THE INTERNATIONAL CYCLOPÆDIA.

STRANGFORD, PERCY CLINTON SYDNEY SMYTHE, 1780-1855; Irish scholar and diplomat; during the period 1817-25, successively British ambassador to Stockholm, Constantinople, and St. Petersburg; in 1825 created Lord Penshurst; author of a translation of the poems of Camoens. His son Percy, 1825-69, was an Orientalist.

STRANGULATION may be defined to be "an act of violence in which constriction is applied directly to the neck, either around it or in the fore part, so as to prevent the passage of air, and thereby suddenly suspending respiration and life."—Taylor's *Principles and Practice of Medical Jurisprudence*, 1865, p. 673. This definition, as Dr. Taylor observes, obviously includes hanging (q.v.). *Hanging* has been already briefly noticed in a special article, but the medico-legal relations of this and the other varieties of strangulation have still to be considered.

When the suspension of a body has not continued for much more than five minutes, and the parts about the neck have not suffered violence, there is a probability that resuscitation may be established; although many cases are recorded when, after only a few minutes' suspension, it has been found impossible to restore life. It is believed that death takes place very rapidly, and without causing any suffering; the violent convulsions that are so often observed being similar to those which occur in epilepsy. A man named Hornshaw, who was on three occasions resuscitated from hanging—a feat which he performed in London for the amusement of the public—stated that he lost his senses almost at once, and other persons who have been restored state that the only symptoms of which they were conscious were a ringing in the ears, a flash of light before the eyes, then darkness and oblivion. The treatment to be adopted after the patient has been cut down may be briefly summed up as follows: exposure to a free current of air, cold affusion if the skin is warm, the application of ammonia to the nostrils, of mustard poultices to the chest and legs, and of hot water to the feet, and the subsequent abstraction of blood, if there should be much cerebral congestion; artificial respiration should also be tried if the above means fail to re-establish the respiratory process. From the post-mortem appearances, together with circumstantial evidence, the medical practitioner is not unfrequently called upon to decide such questions as these: Was death caused by hanging, or was the body suspended after death? Was the hanging the result of accident, homicide, or suicide? For the full discussion of these questions the reader is referred to chap. 53 of Dr. Taylor's volume. In case of strangulation from other causes than that of hanging, the post-mortem symptoms are similar, but the injury done to the parts about the neck is commonly greater. In manual strangulation, the external marks of injury will be in front of the neck, about and below the larynx; and if death has been caused by a ligature, the mark round the neck will be circular, whereas in hanging it is usually oblique. The internal appearances are much the same as in the case of hanging.

STRANGURY (Gr. *strangæ*, that which oozes out, *oureo*, I micturate) is perhaps to be regarded as a symptom rather than a disease. It shows itself in a frequent and irresistible desire to pass water, which is discharged, however, in very small quantity, and whose passage from the bladder is accompanied with scalding and cutting pains along the course of the urethra. The pain often extends to the bladder and even to the kidneys, and is sometimes so severe as to implicate the lower bowel (the rectum), and to produce the straining condition known as *tenesmus*. It is usually caused by irritating substances in the urine, especially by *cantharides* or Spanish flies (whose irritant principle is liable to find its way into the renal secretion, whether the above named drug is taken internally or merely applied to the skin as a blistering agent), and by oil of turpentine, when administered internally in small doses, and is generally present in cases of gravel. Severe as the affection is, it is very transitory, and yields readily to treatment.

After the removal of the cause, if it can be recognized and the removal is possible, a dram of laudanum in a wineglassful of starch mucilage should be thrown into the lower bowel, and mild mucilaginous draughts (of barley-water, for example) should be freely given in order to render the urine less irritating. The warm bath is also useful, and if it cannot readily be obtained, hot local fomentations often tend to relieve the pain and allow the urine to pass more freely.

STRANRAER, a royal and parliamentary burgh, seaport, and market town of Wigtonshire, at the head of loch Ryan, 6 m. n.e. of Portpatrick. There are no manufactures, the town depending almost wholly on the agricultural interest. A mail steamer runs daily between Stranraer and Larne, in Ireland. Stranraer unites with the Wigtown burghs in sending a member to parliament. Pop. of parliamentary burgh, '91, 6193.

STRAP, in carpentry, an iron band fixed round two or more timbers, sometimes with branches along each, to hold them all firmly together.

STRASBOURG (Ger. *Strassburg*), a fortified t., formerly the capital of the French department of the Bas-Rhin, but, since 1871, capital of the new German province of Alsace-Lorraine, stands at the confluence of the Ill and the Brutsche, and not far from the left bank of the Rhine, 89 m. n. of Basel, and 312 m. e. of Paris by rail. The citadel, originally built by Vauban, 1684, was demolished by the Germans during the bombardment of 1870, but in 1873 they began to rebuild it, and this, in conjunction with a system of 14 detached forts, being erected at several miles' distance from the walls, will make the position one of great strength. The most celebrated building is the minster, or cathedral, founded in 1015, which is one of the most sublime specimens of Gothic architecture. Of the two western towers, one, that at the s. corner, has not been completed. The other, finished in 1439, rises to a height of 465 ft. above the pavement, making it one of the highest buildings in Europe (Cologne cathedral, 512 feet; Rouen cathedral, 484 ft.). The minster has a remarkable astronomical clock representing the planetary system. Other notable structures are the Protestant church of St. Thomas, with the tomb of Marshal Saxe, and various monuments to distinguished Strasbourgh scholars; the *Temple Neuf*, or new temple, rebuilt since 1870, the synagogue of the Jews, the town-house, the palace of justice, the arsenal, the episcopal palace, and the theater. The University of Strasbourg was the only complete university in France—i. e., the only one which has the full complement of faculties—besides that of Paris. It was founded in 1621, became specially famous in the branches of medicine and philology, went to the ground during the great revolution, and had its place supplied by an *école centrale*. In 1803 a Protestant academy was established, with 10 chairs, for teaching theology, philology, philosophy, and history. Five years later, Napoleon founded an imperial academy, with faculties of law, medicine, physical science, and philosophy; and in 1819 a partial fusion of these academies took place, greatly to the benefit of both. The university was reopened after the Franco-Prussian war, in May, 1872. In 1896 it had during the summer semester 971 students. The famous library of Strasbourg, consisting of nearly 200,000 volumes, and rich in *incunabula* (q. v.), was entirely destroyed by fire during the bombardment in 1870, but has been more than replaced by a library contributed by the Germans. The trade of Strasbourg, especially its transit trade, is very extensive and steadily increasing and it has a great variety of manufactures—machinery, cutlery, musical instruments (pianos and organs), watches and clocks, carpets, oil-cloth, paper, leather, cottons, woollens, silks, jewelry, artificial flowers, perfumeries, bonbons, chocolate, preserves, brandy, potash, tobacco, etc. The beer of Strasbourg and the *pâtés-de-foie-gras* (*gänseleberpasteten*) are famous. The Basel and Baden railways, the railway to Paris, and the communication with Rotterdam and London by means of the Rhine steamers, as well as with the Danube and all the great rivers of France by means of canals, have greatly added to its facilities for conducting commerce. The country round about Strasbourg is fertile and carefully cultivated, with beautiful gardens, mansions, and villages. Pop. '95 (including a garrison of 15,493 men), 135,608, of whom about one-half are Catholics.

Strasbourg, the *Argentoratum* of the Romans, was extant before the time of Cæsar, but is first mentioned by Ptolemy. The Romans had a manufactory of arms here. In the 5th c. it appears to have received the name of *Strata-Burgum* or *Strata-Burgus*, perhaps from the invading Franks, whence the modern German Strassburg and the French Strasbourg. It became a free town of the German empire, and in 1681 passed with the rest of Alsace into the hands of the French, under whom its population and prosperity greatly increased. On Sept. 28, 1870, after a bombardment of seven weeks, Strasbourg surrendered to the Germans, and in 1871 was annexed to Germany.

STRATEGY is defined by military writers to be the science of maneuvering an army out of fire of the enemy, as *tactics* is the art of managing it in a battle, or under fire. Strategy is the greater science, as including all those vast combinations which lead to the subsequent available displays of tactics. A good strategist has to attend to the establishing of his bases and depots, although some brilliant generals have dared to act without these last aids—notably, Sherman in America in 1864, and Wellington in 1813, advancing from Portugal through Spain into France. The strategist must know how to diffuse the influence of his arms over a broad area, while yet holding his force well in hand to strike crushing blows. Such was Wellington's Salamanca campaign; in which,

though retreating himself to his former base, he compelled the French to evacuate Valentia.

Strategy must not be confounded with stratagem, although there is relationship between the two. Stratagem is any device for deceiving the enemy as to the point or strength of an attack. Such are ambuscades, feints, bugle-calls to imaginary troops, concealment of infantry by clouds of cavalry, and many other efforts.

STRATFORD, a suburb of London in the borough of West Ham, about 4 miles east of St. Paul's. It is the seat of various and extensive manufactures. There are flour-mills, distilleries, and chemical works. In the town and its suburbs, many London merchants have built residences. The prosperity of the town has been much increased by its connection with the Eastern Counties railway. Pop. '51, 10,586; '61, 15,994; '91, 42,982.

STRATFORD, city, port of entry, and co. seat of Perth co., Ontario, Canada; on the Avon river, and the Grand Trunk and the Georgian Bay and Lake Erie railroads; 88 miles w. of Toronto. It has good waterpower; flour, salt, and planing mills; manufactories of iron castings, mill machinery, steam engines, woolen goods, leather, boots and shoes, and farming implements; Grand Trunk railroad shops; several churches; private and branch banks; one of the handsomest railroad stations (the Grand Trunk) in the province; and attractive co. buildings. The imports and exports of merchandise average about \$600,000 each per annum. Pop. '91, 9,501.

STRATFORD-DE-REDCLIFFE, **STRATFORD CANNING**, Viscount, English diplomatist, was son of a London merchant, and cousin of the celebrated George Canning. He was born 1786, educated at Eton, and entered himself at King's college, Cambridge, in 1805, but left in 1807, on receiving an appointment as *précis* writer in the foreign office. He was appointed secretary of embassy at Constantinople in 1808; and on removal of his chief, Mr. Adair, to Vienna, 1810, remained as minister plenipotentiary, and as such effected the important *Treaty of Bucharest* between Russia and Turkey. He was sent as envoy to Switzerland in 1814. About this time he published an ode full of spirit and power, entitled *Buonaparte*. It is called by lord Byron a "noble poem." In 1820 he went as plenipotentiary to the United States, and remained at Washington three years. In 1824 he was sent on special missions to St. Petersburg and Vienna. In 1825 he was appointed by Mr. Canning, then foreign secretary, as ambassador extraordinary to the sublime porte. Here his good offices were warmly exerted on behalf of the Greeks. In 1831 he was accredited with a special mission to Turkey, to fix the boundaries of the new kingdom of Greece, and to settle the treaty in virtue of which Otho ascended the Greek throne. He went to Madrid and Lisbon on a special mission in 1832. He had previously sat in the house of commons for Old Sarum and Stockbridge during a brief interval in his diplomatic career. In 1834 he was elected for King's Lynn, which he represented until 1841, when, having twice refused the governor-generalship of Canada, he was appointed by the government of sir Robert Peel ambassador at Constantinople. Here his influence was strenuously exerted in the cause of civilization and progress. In 1852 the Derby administration recommended the crown to confer upon him the title and dignity of viscount. When the long-standing quarrel between the Greek and Latin monks in Palestine involved the powers of Europe in the struggle, Stratford remembered how the emperor Nicholas of Russia had, from 1829 to 1853, sought to establish a predominant influence, excluding all others, over the porte, with the view of settling the future destinies of Turkey to the profit of Russia when the propitious juncture arrived. At the time when Prince Menchikoff was sent to Constantinople upon a mission from the czar, Stratford was absent in England on leave. He returned to Constantinople in April, 1853, and prepared to resist Menchikoff's demands. The keenly contested diplomatic struggle between Stratford and the Russian ambassador-extraordinary is narrated with dramatic power by Mr. Kinglake in his *Invasion of the Crimea*, who calls Stratford the "Great Eltchi." Stratford's influence with the Porte prevailed, for, to adopt the words of Mr. Kinglake, "as though yielding to fate itself, the Turkish mind used to bend and fall down before him;" and he placed on England the responsibility of a defensive alliance with the sultan against the czar. As Russia would not withdraw her troops from the principalities, the sultan declared war against Russia, and France and England came to the aid of the Porte. Stratford retired from the Turkish embassy in 1858 upon a pension. He afterwards took a frequent part in the debates of the upper house on questions of foreign policy. He was created a Knight of the Garter in 1869. In 1873 he published *Why am I a Christian?* a work on the evidences of Christianity, and in 1876 a play, *Alfred the Great in Athelney*. He died Aug. 14, 1880.

STRATFORD-UPON-AVON, a municipal borough and township of England, in the county of Warwick, and 8 m. s.w. of the town of that name, is situated on the right bank of the river Avon. Pop. '91, 8318. The town is neatly built, with wide, pleasant streets, containing numerous quaint, half-timbered houses. Some trade is carried on in corn and malt. Stratford-upon-Avon is the birthplace of Shakespeare. The house in which he was born is still preserved, and there is a Shakespeare Memorial building, including a theater and a gallery of Shakespearian paintings, and a library of rare Shakespeariana. The great poet is buried in the parish church.

STRATH, a Gaelic word signifying a broad valley, is often prefixed in the n. of Scotland to the names of rivers, as Strathearn, Strathallan, Strathnairn, Strathspey, in each of which cases it signifies the open valley through which the river flows. In such cases, however, as Strathmore (great valley), it simply signifies a valley-like depression. In the s. of Scotland, the word is not used, the Northumbrian word *dale* being used instead, as Clydesdale, Annandale, Teviotdale, Tweeddale.

STRATHAVEN, a t. of Scotland, in Lanarkshire, about a mile w. of Avon Water, and 14 m. s.e. of Glasgow. On the n. side is the picturesque ruin of Avondale castle, and from 5 to 7 m. s.w. are the battle-fields of Drumclog and Loudoun Hill. The more recently built part of the town is neat and spacious. Pop. '91, 3478, chiefly engaged in weaving and trading in cheese and cattle.

STRATHCLYDE. In the 8th c., the ancient confederacy of the Britains was broken up into the separate divisions of Wales and English and Scottish Cumbria. Scottish Cumbria, otherwise called Strathclyde, thenceforth formed a little kingdom, comprising the country between Clyde and Solway, governed by princes of its own, and having the fortress-town of Alclyde or Dumbarton for its capital. Becoming gradually more and more dependent on Scotland, it was annexed to the Scottish crown at the death of Malcolm I., on failure of the line of native sovereigns. Edgar bequeathed Strathclyde to his youngest brother David, again separating it from the crown of Scotland, which went to his intermediate brother, Alexander I. David held it throughout Alexander's reign in spite of that king's opposition, and on Alexander's death without issue in 1124, it was permanently reunited to the Scottish kingdom under David I.

STRATHMORE (the Great Valley), the most extensive plain in Scotland, is a low-lying tract extending across the country from Dumbartonshire n.e. to Stonehaven in Kincardineshire, is bounded on the n. by the great mountain-rampart of the Highlands, and on the s. by the Lennox, the Ochil, and the Sidlaw hills, and is 100 m. long and from 5 to 10 m. broad. In a stricter sense, however, Strathmore proper extends only from the neighborhood of Perth to that of Brechin in Forfar, a distance of about 40 miles.

STRATHSPEY, a Scottish dance resembling the Reel. Its name is derived from the strath, or valley of the Spey in the north of Scotland, where it was first danced. The music of the Strathspey consists of broken or dotted notes preceding longer ones known by the name of the Scotch snap, and the dance abounds in jerky motions, which call every movement of the body into play. The name of Neil Gow (1727-1807) is associated with the Reels and Strathspeys of Scotland. He was the greatest player on the fiddle of Scottish dance music, and he also collected the old Reels and Strathspeys, and other national music of Scotland. Burns wrote verses to many of the oldest Strathspeys, among which are: "Lassie wi' the lint-white locks," "Green grow the rushes, O," and "Whistle o'er the lave o't."

STRATIO TÊS, a genus of plants of the natural order *hydrocharideæ*, having a two-leaved spathe with numerous barren flowers, one female flower in each spathe. *S. aloides*, popularly called WATER SOLDIER, is common in lakes and ditches in the e. of England. It is a singular plant with numerous leaves, which are strap-shaped, and spring from the root, from which also springs the two-edged flower-stem, bearing the spathe with beautiful and delicate white flowers. In autumn the whole plant disappears, the root alone remaining at the bottom of the water, from which a number of young plants arise in spring, filling up ditches, so that nothing else can grow in them. It is a very ornamental aquatic plant.

STRATTON, CHARLES SHERWOOD, 1838-83; b. Bridgeport, Conn.; d. N. Y. He was engaged by P. T. Barnum, 1852, and traveled under the name of General Tom Thumb; at the time of the engagement he weighed under 16 lbs., and was not two ft. high. He was exhibited in Europe, 1854, and drew great attention. He was married to Lavinia Warren, also a curiosity of smallness, 1863, and together they traveled all over the world in company with the minute Minnie Warren and "Commodore" Nutt.

STRATUM, pl. *strata* (Lat. strewn or spread out), the term applied by geologists to the layers into which most of the rocks that form the crust of the earth are divided. It implies that the layers have been spread out over the surface, and that they were formed in this way we may infer from the deposits that are now taking place in lakes and seas into which rivers laden with muddy sediment empty themselves. •

All the aqueous rocks, which cover so large a proportion of the earth's surface, are stratified. They were formed from the abraded materials of older rocks (aqueous or igneous), which have been washed down and rearranged. The kind of rock produced depended upon the material to which the carrying agent had access. Fine mud would produce shales, sand sandstones, and calcareous matter limestones. In a section, these different kinds of rocks are frequently found to interchange within a short space. This is produced either by the water obtaining different materials, or changing its velocity. Thus the fine sediment which has fallen from slowly flowing water may be covered by a layer of sand brought down by a flood, and this again may have spread over it a covering of shells and corals, and such changes may go on alternately for an

the Ural. 8. Double gangue at Freiberg. 9. Run and ramification of gangues at Freiberg.

indefinite period. Each of the different beds composed of the same kind of material is called a stratum. Thus, in the series mentioned, there would be a "stratum" of clay, one of sand, and then one of calcareous matter. An assemblage of strata having a common age is called a "formation," and this term is also extended to rocks which agree in their composition or origin. Thus, we speak of stratified and unstratified, aqueous and igneous, fresh-water and marine, primary and secondary, metalliferous and non-metalliferous formations. As a formation is composed of many different beds, so a stratum is frequently made up of several "laminae" or "layers." The laminae have a more or less firm cohesion, but the strata easily separate from each other. Sometimes the cohesion of the laminae is so great that it is as easy to split the rock against as with the grain. In such compact rocks the lamination is obscure, or altogether imperceptible in fresh specimens, but whenever they are exposed to the influence of the weather, it becomes obvious. The laminae have been produced by short interruptions in the deposition, similar to what might be the result of tidal or other intermittent action. The degree of cohesion may be the result of rapid succession in the acts of deposition, but it is frequently produced by metamorphic action subsequent to deposition. The planes of stratification want the complete coalescence characteristic of lamination; when the contiguous layers are closely united, it is the result of the adhesion of two bodies, and not of their coalescence into one. In addition to accompanying illus., see GEOLOGY, vol. VI.

STRAUBING, a t. of Lower Bavaria, on the right bank of the Danube, 25 m. s.e. of Ratisbon, lies in a very fertile valley, and carries on a river-trade in corn, cattle, and horses. There is a monument to Agnes Bernauer (q.v.). Pop. '95, 15,596.

STRAUSS, DAVID FRIEDRICH, author of the famous *Leben Jesu*, was b. on Jan. 27, 1808, at Ludwigsburg, in Würtemberg. His education was begun in his native town, and completed in the theological seminaries of Blaubeuren and Tübingen. In 1830, his head filled with Hegel's philosophy and Schleiermacher's theology, he entered on the simple life of a country pastor, but already in the following year he was in Maulbronn acting as professor in the seminary, and went thence to Berlin for six months to continue his Hegelian studies, and hear the lectures of Schleiermacher. Returning to Tübingen in 1832, he became *repetent* in the theological seminary, and in the next years held also philosophical lectures in the university as a disciple of Hegel. Known as yet only to a narrow circle, he became all at once a man of mark by the publication, in 1835, of his *Life of Jesus critically treated*; translated into English by George Eliot in 1846. In this work, written from the point of view of a Hegelian philosopher, and designed only for the learned, he attempted to prove the received gospel history to be a collection of myths gradually formed in the early Christian communities, and, sought by an analytical dissection of each separate narrative, to detect, where it existed, a nucleus of historical truth free from every trace of supernaturalism. The book made a real epoch in theological literature, and produced a violent excitement in and out of Germany, calling forth numberless replies from opponents, frightening many by its bold disregard of consequences back into the ranks of orthodoxy, and stirring up others to similar investigations. The first consequence to the author was his dismissal from his academical position in Tübingen, and transference to the lyceum of Ludwigsburg. He resigned the new post, however, very soon in 1836, and retired into private life at Stuttgart, to have leisure to defend himself. In 1837 he published his *Streitschriften* against his opponents; and in 1838 *Zwei friedliche Blätter*, a more conciliatory exposition of his views. Early in 1839 he was called by the board of education in Zürich to be professor of dogmatics and church history in the university; but the step raised such a storm of opposition among the public that the proposition had to be dropped, and even the government itself had to resign in the same year. Thrown back on his literary labors, Strauss, who had published during the year his *Charakteristiken und Kritiken*, sent forth shortly afterward his second great work, *Die Christliche Glaubenslehre*, a review of Christian dogma "in its historical development and its struggle with modern science" (Tüb. 1840-41). This formed a natural sequel to the purely critical investigation of the origins of Christianity in the first work. When Strauss, after a long period of silence, next appeared on the literary field, it was no longer as a professed theologian. In 1847 he drew attention by a work entitled, *Der Romantiker auf dem Throne der Cäsaren, oder Julian der Abtrünnige*, full of direct allusions to the political situation of the day. His fellow-townsmen put him forward as a candidate for the German revolutionary parliament of 1848, but he was unable to stand against the clerical influence brought to bear upon the country-people of the district. His speeches on this occasion were published under the title of *Seix Theologico-political Popular Addresses*, and his native place compensated the defeat by sending him as its representative to the Würtemberg diet. From this position, however, when he unexpectedly displayed conservative leanings, and incurred a vote of censure from his constituents, he retired before the end of the year. A life of the Swabian poet Schubart (1849), and another biographical work, *Christian Märklin, a Picture of Life and Character from the Present* (1851), giving an insight into his own mental development, were his next literary efforts, before another period of silence. His third period of activity was opened in 1858 by a remarkable life of the reformer, Ulrich von Hutten (Eng. trans. 1874), followed up by the publica-

tion of Hutten's *Dialogues* in 1860. These books, though primarily of strictly historical interest, were nevertheless calculated for the present state of religious affairs in Germany, and contained fiercely contemptuous denunciations of the tactics of the reactionary party in the church. A collection of miscellaneous *Minor Writings* appeared in 1862, and a new *Life of Jesus, composed for the German people*, in 1864 (Eng. trans. 1865). The title of the work indicates its popular cast, the peculiar features of it being a long critical statement of the labors of others in the same field down to the present day, and an attempt to construct a life out of all the positive results that have been gained. The mythical hypothesis is retained, but applied differently. Still later publications which appeared in 1865 are *Der Christus des Glaubens u. der Jesus der Geschichte* (Berlin), a criticism of the newly published lectures of Schleiermacher on the life of Jesus, and a brochure, *Die Halben u. die Ganzen*, directed against Schenkel and Hengstenberg. The polemic against Schenkel, professor of theology in Heidelberg, a leader of the liberal party in the church of Baden, and author of the *Charakterbild Jesu* (1864), arose out of an earlier notice of this book by Strauss. In 1872 he published his last work, *Der alte und der neue Glaube*, in which he endeavors to prove that Christianity as a system of religious belief is practically dead, and that a new faith must be built up out of a scientific knowledge of nature. Strauss died in 1874. An edition of his collated works (*Gesammelte Schriften*) began to be published in 1876. The literary, critical, and polemical powers of Strauss must be pronounced to be of the highest order. No more effective German prose than his has been written since Lessing.—See *Life of Strauss*, by E. Zeller (Eng. trans. 1874).

STRAUSS, JOHANN, 1804-49, b. Vienna; was a member of Lanner's orchestra, and then gave concerts with a band he organized in the principal cities of Germany. His three sons have become known as composers of dance music. The eldest son, **JOHANN, b. 1825**, is music director at Vienna to the emperor of Austria. He organized a band which played with great success in all the large European cities. In 1872 he came to the United States to conduct an orchestra of 1000 performers in his own compositions at the Boston Peace Jubilee. He has composed, besides his well-known waltzes, many operettas, among others: *Indigo* (1871); *Die Fledermaus* (1874); and *Cagliostro* (1875); *La Tsigane* (1877); *The Queen's Lace Handkerchief* (1881); *The Merry War* (1881); *A Night in Venice* (1883); *The Gypsy Baron* (1885); *Ritter Pasman* (1892). The second son, **JOSEF, 1827-70, b. Vienna**, composed about 300 pieces of dance music.—**EDUARD**, the youngest son, is the leader of an orchestra in Vienna, and has composed about 200 pieces.

STRAW BAIL. See **BAIL**.

STRAWBERRY. *Fragaria*, a genus of plants of the natural order *rosaceæ*, suborder *roseæ*, tribe *potentillidæ*, remarkable for the manner in which the receptacle increases and becomes succulent, so as to form what is popularly called the fruit; the proper fruit (botanically) being the small *achenia* which it bears upon its surface. The genus differs from *potentilla* (q.v.) chiefly in having the receptacle succulent. The calyx is 10-cleft, the segments alternately smaller; the petals are five; the style springs from near the base of the carpel. All the species are perennial herbaceous plants, throwing out runners to form new plants; and the leaves are generally on long stalks, with three leaflets, deeply toothed. One South American species has simple leaves. Only one species, the **WOOD STRAWBERRY**, (*F. vesca*), is truly a native of Britain. It is common in woods and thickets. Its fruit is small, but of delicious flavor. Another species, the **HAUTOIS STRAWBERRY** (*F. elatior*), is not unfrequently to be seen in woods and hedges, but has probably escaped from gardens. It is really a native of North America. The many kinds cultivated in gardens are regarded as varieties of these species, and of the **CAROLINA STRAWBERRY** (*F. Caroliniana*), the **PINE STRAWBERRY** (*F. grandiflora*, or *F. ananas*), and the **CHILI STRAWBERRY** (*F. Chilensis*), American species, the leaves and fruit of which are larger than those of the wood strawberry. In no genus, however, are the species more uncertain to which the cultivated kinds are to be referred. Some of these are remarkable for the large size of the fruit. New varieties are continually coming into notice, and the utmost care is necessary to keep the larger and finer varieties from degenerating. The cultivation of the strawberry is most extensively carried on in Britain and in Belgium. New kinds are produced from seed; but plantations of strawberries are generally formed of the young plants, which are abundantly produced by runners. The rows are from 18 in. to two ft. apart, according to the kind. The finest fruit is said to be produced when the plants are kept distinct from each other in the rows, but this is not generally done. Tiles are sometimes placed around the plants and under the fruit; and it is an old English practice to lay straw between the rows, to preserve the fruit from rotting on the wet ground, from which the name strawberry has been supposed to be derived; although more probably it is from the wandering habit of the plant, *straw* being a corruption of the Anglo-Saxon *stræ*, from which we have the English verb *stray*. Strawberry beds require to be renewed after a few years. Strawberries are often forced in hot-houses, in order to produce the fruit at a very early season. The uses of the strawberry as a dessert fruit and for preserves are well-known. There is no more wholesome fruit.

The **ALPINE STRAWBERRY** (*F. collina*), a native of Switzerland and Germany, differs considerably from the other kinds in its taller stems and more erect manner of growth.

The fruit, which is either red or white, is not very large, but is produced in great abundance, and unlike other strawberries, parts from its calyx almost on being touched. The Alpine strawberry continues to produce fruit long after the other kinds.

The **INDIAN STRAWBERRY** (*F. Indica*), a native of the Himalaya, requires only a little protection in Britain from severe frost, and with this care grows luxuriantly and produces fruit in abundance. The flowers are yellow, not white, as in other strawberries, and are not produced upon common flower-stalks rising from the center of the plant as in the other species, but upon single-flowered stalks, which spring from the axils of the leaves upon the runners. The fruit is very beautiful, growing with its apex upward. It is not, however, of good quality.

STRAW-MANUFACTURES. The industrial applications of the straw of wheat are of great commercial importance, especially that of plaiting, which is one of the oldest arts practiced by mankind, many specimens having been found in the tombs of the ancient Egyptians, and mention being made of plaiting by Herodotus and other early writers. The earliest notice we have of its systematic use in Europe as an article of clothing is in the records of the reign of Mary, queen of Scots, who, we are told, observed that the peasants of Lorraine wore hats made of straw plait, and that this manufacture was beneficial to them, and she consequently conceived the idea of introducing it into Scotland, which was done about the year 1562, but without much success. Her son, James I., however, carried it into England, where it soon thrived, and has been from that time a permanent branch of industry. It was first regularly established in Bedfordshire, which has ever since been the chief seat of the trade.

At first, the plait was what is called *whole straw*; that is, the straw was cut into suitable lengths without knots, and merely pressed flat during the operation of plaiting, and so it continued until the reign of George I., when it was in great demand for ladies' hats, and some plait was made of split straw. Since that time, this kind has been chiefly used, and a much improved method has been substituted for the clumsy one of using a common knife for splitting it. The instrument now employed is made of steel, and consists of a number of little square blades set in a circular manner around a stem, which at one end terminates in a point, and at the other is bent and fixed into a handle. The point being inserted into the hollow of the straw, is pressed forward, and cuts it into as many strips as there are blades in the cutting-tool; these vary in number according to the fineness of the work to be produced.

It is found that the fine straw-plaiting, which is now produced better in England than in any other country except Italy, can only be made from one or two varieties of wheat, that called the White Chittim being generally preferred, and next to it the Red Lammas, which only succeed as a straw-crop upon the light rich soils of the more southern of the midland counties. The harvesting is a matter of great anxiety, as the straw is liable to many injuries from wet and other causes. The value of this crop can be best understood by the fact that an acre will yield from 25 to 40 bushels of wheat, and from 15 cwt. to a ton of straw, which, when in good condition, is worth \$35 or \$40.

The crop is bought up by straw-factors, who employ people to draw the straw, and remove the ears, which are all cut off by hand for threshing. The straws are afterward cut into lengths and cleared of the outer sheath or leaf; they are then sorted into various thicknesses by an apparatus consisting of a series of sieves about eight inches in diameter; the boys who usually do this work hold a handful on end over the first sieve, which has the narrowest spaces, and the thinnest straws only fall through it; they are next placed on the second, and so on to the last. As they fall through each successive sieve, they pass down through hollow shafts, through shoots of tin or sheet-zinc into boxes, from which they are removed and tied into bundles ready for the splitters, who next take them in hand and reduce them to strips of the sizes required. In Switzerland straw-plaiting schools exist even in the poorest parts of the subalpine districts, and their products command markets in all parts of the world. The higher instruction extends to the cultivation and acclimatization of various kinds of foreign grasses furnishing all qualities of straw.

Besides its value for plaiting, straw is now much used in the manufacture of paper (q.v.).

In America, it is recorded that from a very early period in the colonial times, the plaiting of straw and its manufacture into suitable goods for domestic use was a common home industry in many New England and other northern households. As these goods were necessarily crude and ungraceful, the wants of the wealthier classes were usually supplied by importation from abroad—principally from Italy. In the early part of this century, however, when the prolonged European wars cut off communication with Italy, more attention began to be paid to this branch of industry, and various manufactories were started which supplied a limited and local trade. But it was not until 1825–30 that the business grew to any real importance or covered any great extent of territory. About that time some of the more enterprising New York and Massachusetts houses sought to develop their facilities so as to reach those portions of the country where straw goods were little known, and the business soon assumed immense proportions. For many years goods were made largely from the straw raised and plaited in this country—the plaiting being done chiefly by females during the intervals of household work—but the cheapness and superiority of foreign braids, in

some cases, again drove this form of American labor out of the market. The chief domestic braids now left are the "Mackinaw" straw, which is raised and plaited in Canada and in a few localities in the north-western states, and the palm-leaf, grown in Cuba and split and braided in New England. More than 50 per cent of all the straw goods manufactured in this country are made from the Canton straw imported from China. The Luton straw from England, and the Leghorn from Italy, are also largely used, and small quantities of other varieties are imported from Switzerland, Bohemia, France, Malaga (Spain), Manila, and Central and South America. The total value of the importations is estimated at about \$2,000,000 annually. Straw hats and bonnets are sewn chiefly by the Knowlton and Bosworth sewing machines, which are run by steam and which can turn out as many as 100 hats each in a day. These machines are of American invention and their use is gradually extending abroad. The goods are pressed and blocked into shape at the rate of four a minute, by another machine of American origin. The total value of the straw goods manufactured in the United States was, in 1870, \$7,282,086, and in 1880, \$9,345,759. According to the census of 1890 there were six establishments manufacturing straw goods, exclusive of hats, in the United States. These are distributed between the Dist. of Columbia, Indiana, Iowa, Kentucky, Maine, Maryland, Minnesota, Tennessee and Virginia. The aggregate capital employed in these manufactures is \$106,750, the number of hands employed 433, and the annual value of their products \$214,257. The imports of manufactured straw into the United States for the year ending June 30, 1895, amounted to \$1,283,429, and of unmanufactured for the same year \$24,544.

STRAZNICKY, EDWARD R., PH.D., 1820-76; b. Moravia; graduated at a university in Vienna, where he became an expert linguist, and took the degrees of M.D. and PH.D. He was made intendant of an estate belonging to a wealthy Austrian nobleman, but, becoming involved in the struggle of Hungary for liberty, was compelled to leave his country, notwithstanding the fact that one of his near relatives was a field-marshal in the Austrian service. He arrived in New York penniless, and was forced to submit to severe privations during his first years in America. His ability and education, however, at length secured him influential friends, and he was made secretary of the American geographical society, and in 1859 second assistant librarian in the Astor library. He rose through the different grades until, on the retirement of Hon. Francis Schroeder, superintendent of the library, he was appointed to that position.

STREATOR, a city in Lasalle co., Ill., on the Vermillion river and the Atchison, Topeka, and Santa Fé, the Burlington route, the Chicago and Alton, the Indiana, Illinois, and Iowa, and the Wabash railroads; 16 miles s. of Ottawa, the co. seat. It is in an agricultural, coal-mining, and valuable clay region; contains a high school, Y. M. C. A. building with hall, reading-room, and gymnasium, opera house, public library, several national banks, and about 25 churches; and has manufactories of paving and fire brick, sewer pipe, tile, plate, window, flint, and fancy glass, glass bottles, machinery, flour, etc. Pop. '90, 11,414.

STREET, ALFRED BILLINGS, 1811-81; b. N. Y.; studied law and practiced a few years at Monticello, N. Y., but after 1838 lived at Albany. He wrote many poems of considerable merit, some of which have been translated into the German. Among his writings were: *The Burning of Schenectady, and other Poems* (1842), and *Frontenac, a Tale of the Iroquois in 1696* (1849). In prose, he wrote biographical and historical sketches, *Forest Pictures in the Adirondacks* (1864), and *The Indian Pass* (1869). He was for many years state librarian.

STREET, AUGUSTUS RUSSELL, 1791-1866; b. New Haven, Conn.; graduate of Yale college, 1812; studied law; inherited a large estate; gave \$300,000 to Yale college, founding the Street professorship of modern languages. He erected, and partially endowed, the Yale school of fine arts, and left a sum of money to establish the Titus Street professorship. He lived in Europe, 1843-48; returned to this country and died in New Haven. His daughter married Admiral Foote.

STREET, GEORGE EDMUND, b. England, 1824; educated at the collegiate school, Camberwell, and afterward studied architecture under Gilbert Scott. Among his works are the theological college at Cuddesden, and the churches of St. Philip and St. James, at Oxford, and of St. Margaret, at Liverpool. Among his restorations are Jesus college chapel, Oxford; and Wantage church. Most of his works are in the Gothic style, upon which he has written much. Among his writings are *The Brick and Marble Architecture of North Italy in the Middle Ages* (1855), and *Gothic Architecture in Spain* (1865). D. 1881.

STRELITZ, more properly *streltzi* (arquebusiers), the ancient Russian militia guard, first raised by Ivan Vassilevitch the terrible, in the second half of the 16th century. At that time, and for long afterward, they were the only standing army in Russia, and at times amounted to between 40,000 and 50,000 men. They were located at Moscow in time of peace, in a quarter of the capital which was set apart for them, and, being the bravest and most trustworthy troops in the army, were made objects of special favor and distinctions. But like all such petted corps, the Roman pretorians, the Turkish janizaries, and the Egyptian memluks, their general turbulence, frequent revolts against the government (notably during the Demetrian insurrections), and incessant conspiracies

rendered them more formidable to the Russian government than to external enemies. The strelitz having, at the instigation of the grand-duchess Sophia and the chiefs of the Old Muscovite party, revolted against Peter the Great, that iron-handed ruler caused them to be decimated (1698) in the great square of Moscow, and the remainder to be banished to Astrakhan. The feeble remnant still manifesting their characteristic turbulence and disloyalty, Peter exterminated them almost completely in 1705. Few Russian families at present can claim kindred with the old streltzi, but to this the family of Orloff (q.v.) forms a prominent exception, being descended from a strelitz who was pardoned by Peter the Great while the axe was being raised over him.

STRENGTH OF MATERIALS. The strength of materials depends upon their physical constitution—viz., their form, texture, hardness, elasticity, and ductility.

The resistance of materials in engineering works is tested in reference to various strains; such are—1. Extension or tension; 2. Compression or crushing; 3. Transverse or cross strain; 4. Shearing strain; 5. Torsion or twisting strain.

1. *Extension.*—When a rod is suspended vertically, and a weight attached to its end tending to tear it asunder, all its fibers act equally, and its strength evidently depends on the strength of the individual fibers and their number, that is, the area of cross-section of the rod. The following table gives the resistance to *rupture* of some of the most common materials:

| | Per Square Inch. |
|------------------------------------------------------------|------------------|
| Fine sandstone..... | 200 lbs. |
| Brick..... | 300 “ |
| Common lime..... | 50 “ |
| Portland cement..... | 240 “ |
| Deal (timber)..... | 5 tons. |
| Cast iron (ordinary)..... | 6½ “ |
| “ Stirling's toughened..... | 12½ “ |
| Wrought iron, boiler-plate..... | 20 to 24 “ |
| “ bars..... | 25 “ |
| Cast steel..... | 60 “ |
| Ropes (hemp), four-fifths ton per pound weight per fathom. | |

With regard to the elongation of materials under tensional strain, it has been observed that up to a certain limit, which is different for different substances, the elongation is proportional to the extending force, a physical truth the promulgation of which is due to Hooke (q.v.); up to this limit also the body nearly recovers its original form on the removal of the force; this limit is called the limit of elasticity. When this limit is passed, the permanent elongation or destruction rapidly increases until rupture takes place.

The extension of wrought iron is about $\frac{1}{1000}$ of its length per ton of strain per square inch, and that of cast iron $\frac{1}{8000}$. The limit of elasticity of wrought iron is attained under a strain of 12 tons per square inch; and in the case of American pine $1\frac{1}{2}$ ton per square inch.

2. *Compression or Crushing Strain.*—The strength of pieces of stone, wood, or iron, whose height is small in proportion to their area, and which absolutely crush under the strain, is proportional to the area of their horizontal section. The following table gives the resistance to crushing of some of the more common materials:

| | |
|-------------------|--------------------------|
| Cast iron..... | 50 tons per square inch. |
| Wrought iron..... | 16 “ “ “ |
| Brickwork..... | 30 tons per square foot. |
| Sandstone..... | 200 “ “ “ |
| Limestone..... | 490 “ “ “ |
| Deal..... | 450 “ “ “ |
| Oak..... | 650 “ “ “ |

Up to a certain strain, which is called the limit of elasticity, the diminutions in length of the body are proportional to the compressing force; and are practically the same in amount as the elongations in the case of tensional forces. In the case of wrought iron, the limit is 12 tons per sq.in.; after that strain, its shape and proportions become permanently altered; and where these are of consequence, as in most practical cases, we come to the limit of its utility, which is reached when the load is about 16 tons per sq. inch. It then oozes away beneath additional strain, as a lump of lead would do in a vise.

The mode of ultimate failure of cast iron is quite distinct from that of wrought iron. It crushes suddenly by the sliding off of the corners in wedge-shaped fragments, being a crystalline mass, without sufficient ductility to allow of its bulging horizontally; the angle of rupture at which these wedges slide off being tolerably constant, and varying from 48° to 58°. The limit of elasticity is attained in cubes of deal under a compression of 100 tons per sq.ft.; and in those of oak, 150 tons per sq. foot.

Pillars, round or square, may be divided into three classes—1. Those whose height is not more than 5 times their diameter; 2. Those whose height is between 5 and 25 times their diameter; 3. Those whose height is at least 25 times their diameter. The

first follow the same laws as cubes or pieces of small height above discussed, and are absolutely crushed; their strength being proportional to their cross section. The second are broken across, partly by crushing and partly by bending. The third give way purely from bending as with a transverse strain, and their strength is found by experiment to be directly proportional to the fourth power of their diameter, and inversely proportional to the square of their length. Thus, in the case of two long pillars of equal length, but of which one has its diameter double that of the other, the strength of the former will be 16 times that of the latter; from which will be apparent the advantage of the tubular form for pillars, as it gives a large diameter, combined with lightness.

In the case of long columns whose length is 25 or more times their diameter, if we represent the strength of a long cast-iron column of any dimensions by 1000, the strength of a wrought iron column of the same dimensions will be 1750; of cast steel, 2,500; of Danzig oak, 110; of red deal, 80.

3. *Transverse or Cross Strain*.—When a beam fixed at one end is loaded with a weight at the other, it is bent from its original form, and takes a curved shape. The fibers on the upper or convex side of the beam are extended, and those on the under or concave compressed; while at the middle of the beam, there are fibers which are neither extended nor compressed, where the compression ends and the extension begins: this surface of fibers is called the neutral surface. As long as the beam is not strained beyond the limit of its elasticity, the extensions and compressions for a given strain are nearly equal, and therefore the neutral surface passes through the center of gravity of the cross section of the beam.

If we strain the beam beyond this limit, and approach the breaking strain, the extensions and compressions are no longer equal, and therefore the position of the neutral surface is not readily determined. For example, in the cases of stone and cast-iron, the amount of compression is much less than that of the extension, and in the case of timber greater. Also the extensions and compressions are no longer proportional to the strains. From these causes the position of the neutral axis, and the amount of strain on the different parts of the cross section at the moment of rupture, cannot be determined by theory.

Different theories have been proposed to determine the relative strength of similar beams, while their absolute strength is left to experiment. That of Galileo consists in supposing the beam incompressible, and that it gives way by extension turning round the lower edge, each point of the section giving an equal resistance before rupture. That of Mariotte and Leibnitz supposes the beam in like manner to turn round its lower edge, but considers that the resistance given out by each point of the section is proportional to its distance from that edge.

The theory now generally adopted consists in supposing the extensions and compressions to continue up to the point of rupture proportional to the strains, as is actually the case up to the limit of elasticity, and therefore, that the beam turns round a neutral axis, passing through the center of gravity of the cross section, the force given out by each point being proportional to its distance from the neutral axis. This last theory is found to give the best results in the case of timber and wrought-iron, especially wrought-iron arranged in the forms usual in girders. The second represents nearly the method of failure of stone, and the first that of cast-iron.

Though none of these theories give accurate results, they yet give us means of determining, from particular experiments, the strength of any other beam whatever. For example, these theories agree in giving the strength of a rectangular beam to be proportional to the area of cross section multiplied by the depth, and inversely proportional to the length of the beam, since the strain increases directly as the length. This, when expressed mathematically, is

$$W = C \frac{bd^2}{l} \quad (\text{I.})$$

Where w = breaking weight in tons.

b = breadth of beam in inches.

d = depth of beam in inches.

l = length of beam in inches.

C = a constant number for beams of the same material, to be determined by experiment.

This result is borne out by experiment—that is to say, the constant C being determined by experiment on one beam, the strength of any other is found by multiplying its breadth by the square of its depth and by the constant C , and then dividing by its length. In the case of a beam supported at each end and loaded by a weight in the middle, the strength is also given by the formula,

$$W = c \frac{bd^2}{l} \quad (\text{II.});$$

but c , in this case, is 4 times the value of C in the formula for a beam loaded at one end

The truth of this may be seen from the consideration that the beam may be treated as if it were two beams, each fixed at the middle point at one end, and pressed upward by the reaction of the supports at their other ends. This reaction is evidently equal to $\frac{W}{2}$; so that the breaking weight of the whole beam, supported at both ends, resolves itself into that of a beam of length $\frac{l}{2}$, acted on by the weight at one end $\frac{W}{2}$; this by formula (I.) is,

$$\frac{W}{2} = C \frac{bd^3}{l}$$

$$\text{or, } W = 4C \frac{bd^3}{l} = c \frac{bd^3}{l};$$

therefore, $c = 4C$ or $C = \frac{1}{4}c$.

Experiments on the transverse strength of beams are generally made by loading in the middle beams supported at both ends. The following table, from experiments by Mr. Barlow, gives the value of c for beams supported at each end and loaded in the middle:

| | Tons. |
|-------------------|------------------|
| Cast-iron..... | 13 $\frac{1}{2}$ |
| Wrought-iron..... | 12 |
| English oak..... | 2 $\frac{1}{2}$ |
| Red pine..... | 2 $\frac{1}{5}$ |

These numbers when substituted in the formula give the breaking weight, one-third of this will be the safe load in practice. The transverse strength of cast iron is considered so good a test of its value, that in specifications of iron work, it is generally required to be of such a quality that a bar of it, of certain dimensions, will bear a specified weight at the center; for example, "that a bar of it, 42 in. long, 2 in. deep, and 1 in. wide, set on bearings 36 in. apart, shall bear, without breaking, 30 cwt. suspended in the middle." If a beam be loaded uniformly over its length, it will bear twice as much as if the load be condensed at the center. Also if the load be placed some distance from the center, the load it will bear is to the load borne at the center inversely as the rectangle of the segments into which the beam is divided by the point of application of the load are to one another, from which it follows that it will bear less weight at the center than at any other point.

Since the strength of a rectangular beam is proportional to the square of the depth, multiplied by the breadth, it is evident that by increasing the depth and diminishing the breadth we shall, up to a certain limit, increase the strength of a beam without increasing its weight; for example, let A and B be the sections of two beams, of which A is 2 in. broad and 2 deep, and B 4 in. deep and 1 in. broad, they are of the same sectional area—viz., 4 sq. in., but the strength of B is to the strength of A as $4^2 \times 1$ is to $2^2 \times 2$, or as 16 to 8, that is 2 to 1, that is to say, B is twice the strength of A. Hence arises the advantage of the double T forms so generally used in iron girders, the strength of which forms are proportional to the area of the top or bottom plates multiplied by the depth. For a beam of this form loaded at the center, the following formula will give the breaking weight:

$$W = C \frac{ad}{l}$$

Where a = the area of the top or bottom flange in sq. inches.

C = { 4 times the destroying load per sq. in. of the material, under direct tension or compression in tons.

d = depth of the beam in feet.

l = length between supports in feet.

W = breaking weight at the center in tons.

For cast-iron beams, when the area of the bottom flange is made 6 times that of the top, which has been found by experiment to be the best arrangement, and the strength is measured by the tensional strain, supported by the bottom flange, that is, 6 $\frac{1}{2}$ tons per sq. inch.

$$C = 6\frac{1}{2} \times 4 = 26 \text{ tons.}$$

For wrought-iron beams,

$$C = 4 \times 20 = 80 \text{ tons for the lower flange,}$$

$$\text{and } C = 4 \times 16 = 64 \text{ tons for the upper flange.}$$

FIG. 1.

The principle of hollow structure prevails both in nature and art, wherever strength and lightness have to be combined. It is seen in the stems of plants, especially of the grasses; the bones of animals are also hollow, and those of birds, where great lightness is required, are most so. A feather, with its hollow stem, is perhaps the best instance of the union of strength and lightness that could be given. In art, again, we have hollow metal pillars; and sheet-iron for roofing and other purposes is *corrugated*, or bent into ridges and furrows, to give it depth. Each ridge or furrow is, as it were, half a tube, and resists bending with twice or thrice the energy it would if flat.

The most striking application of the principle of hollow structure is seen in tubular bridges. The object being to resist a vertical strain, the form is made rectangular, and the chief mass of the material is thrown into the top and bottom. The tube may, in fact, be considered as an immense beam or girder constructed on the principle of the double T-iron girder, the top and bottom being the two flanges, and the two sides serving to connect them instead of the one rib in the middle. As it is constructed of plate-iron, the top requires more metal than the bottom, in order to resist the compression; but instead of putting the metal into one thick plate, or into several plates, laid the one on the other, it is made to form a set of minor tubes or cells, which give additional stiffness and strength to the whole tube. The floor, in like manner, contains cells. Each of the tubes over the Conway bridge is 24 ft. high, 14 ft. wide (outside), and 420 ft. long, and weighs 1,300 tons; yet these enormous hollow beams sustain not only their own weight, but the heaviest railway-trains without sensible deflection.

Fig. 2 represents an ingenious contrivance for strengthening the wooden beams supporting a bridge. An iron rod fixed to the beam AB at the two ends, is kept at a distance by struts c, c' . The beam cannot now be bent downward without stretching the rod; which thus has to bear the tensive strain while the beam itself sustains only the compressive strain.

Another way of removing part of the strain from a girder, is to fix a king-post and two oblique pieces on its upper side. The whole is now one composite girder; and when any weight bears upon it, the whole of the compressive strain is thrown upon the oblique pieces, and only the tensive strain is left for the beam to sustain.

When a beam AB is fixed at one end, and loaded at the other, the strain is greatest at B, and is less at other points c, c' , in proportion as Ac, Ac' , the levers at which it acts, are less than AB. The beam may therefore be made to taper off toward the end, and we may determine the exact form the beam should have, in order to be equally strong at every point. For supposing the breadth uniform, the strength increases as the squares of the depths $c'd', cd$, while the strain increases as the levers Ac', Ac ; and thus, if $Ac:Ac'::cd^2$ to $c'd'^2$, the strengths are equal at those points. This proportion will always hold good, if the curve of the beam is that of a parabola; and, accordingly, this is the shape given to the beams of steam-engines.

In beams supported at both ends, the strain is greatest in the middle; girders are therefore made strongest in the middle, and taper toward the ends.

4. *Shearing Strain.*—This force is called into play when a plate is cut by shears, or when a riveted or bolted joint is torn asunder, in which case the rivets are sheared across. The effect of it is to cause the particles in one plane to slide over those in another; this is resisted by their mutual coherence, and the magnitude of the resistance depends on the number of the particles, that is on the area of cross-section of the body sheared. The following laws are the result of experiment: 1. The ultimate resistance to shearing is proportional to the area of section of the bar sheared. 2. The ultimate resistance of any bar to a shearing strain is nearly the same as the ultimate resistance of the same bar to a direct longitudinal strain.

5. *Torsion.*—If one end of the axle or shaft of a wheel is immovably fixed, and a power acts at the circumference of the wheel (or at the end of a lever or winch), the power may be so increased as to twist the shaft asunder at its weakest point. If a shaft A has twice the diameter of another shaft B, there will be four times as many fibers in the section of fracture of A, to resist the twist, as in that of B. But as the separation takes place by the one end of the fracture turning round upon the axis of the shaft, making the ends of the separating fibers describe circles, those fibers that are furthest from the center will have the greatest power of resistance, and the sum of their moments,

FIG. 2.

FIG. 3.

or their united effect, will be in proportion to their mean distance from the center. This mean distance in A is twice that in B; therefore, the resistance in A is 2×4 , or 8 times the resistance in B. Generally, the strength of shafts to resist torsion is as the cubes of their diameters. The torsive strengths of shafts 1 in. diameter, and with weights acting at 1 ft. leverage, being found by experiment for different materials; the strength of shafts of other dimensions is found from these "constants" by multiplying by the cube of the diameter, and dividing by the length of the lever. It is evident that the torsive strength of a hollow shaft will be greater than that of a solid one of the same quantity of material, on the same principle that its transverse strength is greater. The rule used by Boulton and Watt for calculating the diameters of their wrought-iron shafts was as follows:

$$\text{Diameter of shaft in inch.} = \sqrt[3]{\frac{120 \times \text{horse-power.}}{\text{Revolu. per minute.}}}$$

This is found to make the shafts rather too light; and the following variation gives safer practical results:

$$\text{Diameter of shaft in inch.} = \sqrt[3]{\frac{240 \times \text{horse-power.}}{\text{Revolu. per minute.}}}$$

STREPSIPTERA (Gr. twisted-wings), an order of insects called RHAPIPTERA (Gr. fan-winged) by Latreille, but first established by Kirby. The first-known species were observed by Rossi, and referred by him to the order *hymenoptera*. The order strepsiptera consists of a small number of species, very singular in structure and habits, apparently forming a connecting link between *coleoptera* and *hymenoptera*. The species are all small, and in their larval state, live parasitically in the bodies of bees and wasps. Their natural history has been the subject of much attention since they were discovered; but much still remains obscure. The species form the two genera, *stylops* and *xenos*.

STRETCHING-COURSE, in masonry or brick-work, is a course in which the stones or bricks are placed with their longest sides along the face of the wall. The stones are called *stretchers*, as those placed at right angles to them with their end exposed are called *headers*.

STRETTO (Ital. bound), in music, a term which signifies that the movement to which it is prefixed is to be performed with rapidity gradually accelerating toward the close.—The term *stretto* is also applied to the recurrence in a fugue of the subject in one part before it has come to a close in another. See FUGUE.

STRIÆ, the fillets between the flutes of columns, pilasters, etc.

STRICKLAND, AGNES, an English authoress, the daughter of Thomas Strickland, esq., was b. at her father's seat, Roydon Hall, near Southwold, in Suffolk, in the year 1806. She was the third daughter of a family of six daughters and two sons, nearly all of whom have contributed something to the literature of our time. Her first compositions were mostly in the poetical vein, and consisted of anonymous contributions to periodicals. About the year 1825, however, she published, in conjunction with her sister Susanna (afterward Mrs. Moodie), a volume of *Patriotic Songs*; which was followed, in 1826, by a little volume bearing her own name exclusively, and entitled *Worcester Field, or the Cavalier; a Poem, in Four Cantos, with Historical Notes*, which was favorably received by some of the reviews. *Worcester Field* was followed by *The Seven Ages of Woman, and other Poems* (Lond. 1827); and this by *Demetrius, a Tale of Greece, in Three Cantos* (Lond. 1833), written in the meter of Byron's *Coriair*. In 1836 she published a little volume entitled *Floral Sketches, Fables, and other Poems*; republished in 1861. With this the list of Miss Agnes Strickland's poetical works ends. Among her prose works are: *The Rival Crusoes*, published without date; *The Pilgrims of Walsingham, or Tales of the Middle Ages, an Historical Romance* (2 vols., 1835); *Tales and Stories from History* (1836); *Alda, the British Captive* (1841); *Historical Tales of Illustrious British Children* (1847; new ed., 1858); *Historic Scenes and Poetic Fancies* (1850); *Old Friends and New Acquaintances* (2 series, 1860–61). All these, however, are but of small import in comparison with her well-known work, *Lives of the Queens of England from the Norman Conquest, with Anecdotes of their Courts*, in 12 vols. (Lond. 1840–48; new ed., 8 vols., 1851–52). In this work, the materials for which she discovered by diligently ransacking among the treasures of the British Museum and other great public repositories of historic documents, Miss Strickland was largely assisted by her sister Elizabeth, an assistance which she gratefully acknowledges in her preface. It was dedicated to queen Victoria; and as each volume successively appeared, its picturesque style and anecdotal character made it a general favorite, especially among that class of readers whose object in reading history is rather amusement than philosophical instruction. At the same time it must be owned that in these *Lives* she has added materially to our stock of historical information. Miss Strickland's *Lives of the Queens of England*, concluding with the biography of Queen Anne, have been followed by the *Lives of the Queens of Scotland, and English Princesses connected with the Regal Succession of Great Britain*, in 8 vols. (Edin. and Lond. 1850–59); and these by her *Lives of the Bachelors Kings of England* (Lond. 1861), containing the lives of William Rufus, Edward V., and Edward VI. Miss

Strickland published a novel entitled *How will it End?* (1865); *Lives of the Seven Bishops* (1866). In 1871 she received a pension of £100. She died in July, 1874.

STRICKLAND, HUGH EDWIN, 1811-53; b. England; studied with Dr. Arnold at Laleham; graduate of Oxford, 1832; gave his attention to the special study of geology and ornithology. In 1850 he became reader in geology in the university of Oxford, succeeding Dr. Buckland, and retaining the post till his death. He was one of the founders of the Geological Society, and of the Ray Society, which on account of his representations undertook the publication of Agassiz's *Bibliographia Zoologie et Geologie*, 3 vols. of which he edited. He contributed to scientific periodicals, and was associated with Sir Roderick Q. Murchison in his *Silurian System*.

STRICT CONSTRUCTIONISTS. See PARTY NAMES.

STRICTURE is a term employed in surgery to denote an unnatural contraction, either congenital or acquired, of a mucous canal, such as the urethra, œsophagus, or intestine. When, however, the affected part is not mentioned, and a person is stated to suffer from stricture, it is always the urethral canal that is referred to. Contraction of this canal may be either permanent or transitory; the former is due to a thickening of the walls of the urethra, in consequence of organic deposit, and is hence termed organic stricture; while the latter may be due either to local inflammation or congestion, or to abnormal muscular action: the first of these varieties may be termed inflammatory or congestive stricture; and the second, spasmodic stricture. The last-named form seldom exists except as a complication of the other kinds of stricture. There are two principal causes of organic stricture—the first being inflammation of the canal, and the second injury by violence. Inflammation is by far the most common cause, and gonorrhœa is the common agent by which it is excited. Not unfrequently, stimulating injections thrown into the urethra, with the view of checking the gonorrhœal discharge, excite an inflammatory action, which gives rise to stricture. Fortunately, it is only in exceptional cases that a stricture results from inflammation of the urethra, the inflammation, in the great majority of cases, terminating by resolution, and leaving the canal as healthy as before the attack. It is when the complaint assumes a chronic character that it most commonly lays the foundation of stricture. Stricture from the second cause arises from such cases as falling across spars, scaffolding, ladders, etc., or on some sharp object which punctures the perineum, as from earthenware vessels which break under the sitter.

The earlier symptoms of stricture are a slight urethral discharge and pain in the canal, behind the seat of the stricture, at the time of micturition. The stream of urine does not pass in its ordinary form, but is flattened or twisted; and as the disease advances, it becomes smaller, and ultimately the fluid may only be discharged in drops. The straining efforts to discharge urine often induce tenesmus (q. v.).

As the case advances, the urine becomes alkaline and ropy, and deposits a precipitate when allowed to stand; and attacks of complete retention (q. v.) occur with increasing frequency. But these symptoms are not in themselves sufficient to establish the presence of stricture. It is necessary to examine the urethral canal with a catheter (q. v.) or bougie (q. v.), to ascertain whether an organic obstruction exists, whether one or more strictures are present (as many as eight have been recorded, although four are rare; and one is the most common number), and their caliber. The treatment of organic stricture is too purely surgical to be discussed in these pages: it is sufficient to state that its object is twofold, viz., first, to restore the natural caliber of the canal, so far as this can be safely effected; and, secondly, to maintain this patency, after it has been established.

Spasmodic stricture may occur from any of the following causes: The presence of organic stricture or of inflammation of the mucous membrane; from an acrid condition of the urine; from the administration of cantharides, turpentine, etc.; and from the voluntary retention of urine for too long a time. The treatment consists in the removal of the causes as far as possible, and the hot bath. The inhalation of chloroform sometimes gives immediate relief; and several cases are recorded in which, when the spasm occurred periodically, it was cured by quinine. Inflammatory or congestive stricture commonly arises when a recent purulent discharge from the urethra has been checked by external cold or wet. The patient complains of heat, fullness, and soreness in the perineum; the passage of the urine is extremely painful, the stream being small, and ceasing before the bladder empties. The treatment is much the same as that for retention of urine (q. v.).

STRIGAU, or **STRIEGAU**, a t. of Silesia, Prussia, situated on Strigau Water, 32 m. w.s.w. of Breslau. It has manufactures of woollens and linens. It is famous for the victory gained by Frederick the Great over the Austrians and Saxons in 1745. Pop. '95, 12,627.

STRIGIDÆ, the family of nocturnal birds of prey, or owls (q. v.).

STRIKE, a term borrowed by geologists from the German *streichen*, to extend, and adopted with the technical meaning it has in that language. It is applied to the direction of the outcrop of a stratum—the line which it makes when it appears on the surface of the earth. This line is always at right angles to the dip of the bed. The angle of dip and the direction of strike are determined by a clinometer and compass. A perfectly horizontal stratum can have neither dip nor strike.

STRIKES. Beginning as early as the middle of the 14th c., the opposition of combined labor to the efforts of employers to regulate the price and hours of labor, has been prominent in economic history; though, indeed, the earliest incident recorded in such history, had a peculiar origin, the reverse of what we have just indicated. The terrible plague of 1348 which continued during eight years, destroyed, it is believed, nearly two-thirds of the human race then existing. In London, 50,000 bodies were buried in one grave-yard; in Venice the number of deaths is said to have been 100,000; in Lübeck 90,000; in Spain the disease raged three years, and carried off two-thirds of the people; in the east 20,000,000 perished in one year. One result of this protracted "dance of death" was a scarcity of labor so great that it became a question as to the possibility of providing for the living. Such a condition, not unnaturally, encouraged the craftsmen to increase the price of their services, with the increase of the demand and of the scarcity. In England this assertion of a claim which could not but be obnoxious, was met by parliamentary enactments, "statutes of labor," and other exercise of the power of the governing class. It was the first "strike," and, as ever since, it was met by force. It was an attempt to take unfair advantage of disaster and death. Subsequent strikes for a rise in wages have been occasioned mostly by a preceding act of cutting them down. The introduction of machinery and the factory system into British labor, was the occasion of serious resistance on the part of skilled labor; as was the case also on the continent of Europe and in America. From this time strikes have been common, whenever laborers wished an increase of wages, or a lessening of the hours of labor. The organization of trades-unions made it possible to conduct these movements on a large and powerful scale; and in many instances—particularly in flush times, and when prices were high—they were successful. Not always conducted, however, with a due regard for existing economic conditions, they have frequently proved abortive for their purpose, and powerful only in creating added and permanent distress among the laboring classes. Little record has been kept of the strikes which have occurred in America, but we know that as early as 1830 they occurred in Boston to secure shorter hours of labor; the trades engaged being carpenters and masons. Strikes have occurred since in various manufacturing towns in Massachusetts about every year; sometimes for shorter hours, sometimes for more pay. In some instances these were accompanied by rioting, and sometimes the militia were ordered out to suppress this. In 1834 several hundred laborers employed in building the Providence railroad, struck for higher wages, and became riotous. This was probably the first railroad strike. As a rule, all the early strikes were unsuccessful, though the continual effort after the "ten-hour" rule for daily labor was eventually successful. In Lowell, Lawrence, Fall River, and other cotton-manufacturing towns in Massachusetts, strikes have been frequent; many of them being accompanied by much bitterness and ill-feeling; and all resulting in serious pecuniary loss to all concerned. In all the large cities strikes have formed a prominent feature of the history of labor. Type-setters, stage-drivers, railroad-hands, shoe-makers, and nearly all trades and callings have at one time or another in the past half-century experienced these unfortunate aberrations. But the most important event of this nature, was the memorable railroad strike of 1877; when for two weeks, beginning July 14, 100,000 railroad men and 40,000 miners were "on strike" at once; 6,000 m. of railroad, covering several of the trunk lines, were in the hands of an infuriated mob; the state militia and the U. S. army were found necessary to put down the accompanying riotous conduct, murder, and incendiarism; and more than 2,000 freight cars in Pittsburg alone, with their contents, were destroyed, the destruction of railroad property being estimated at \$10,000,000; while in Chicago, Buffalo, Cincinnati, Albany, and other cities, the amount of loss has never been fully estimated. See COMBINATION, LABOR, TRADES UNIONS.

STRING-COURSE, a thin projecting course of stone or brickwork in a wall, generally ornamented with a molding, and made to go around windows or other openings in the wall.

STRINGENDO, a term used in music to denote a gradual acceleration in the time.

STRINGHALT is a peculiar catching up of the horse's limbs, usually of one or both hind limbs. It is most noticeable when the animal is first brought out of the stable, when he is excited, or made to turn suddenly round; it is a variety of chorea or St. Vitus's dance. Although a serious eye-sore, it does not interfere with usefulness, and is quite incurable.

STRINGHAM, SILAS HORTON, 1798-1876; b. N. Y.; entered the navy as midshipman, 1809; was in several actions in the *President* and *Spark*, under Decatur and Rodgers; and in 1819-21 as lieutenant in command of the *Cyane* and the *Hornet* conveyed the first settlers to Liberia and captured many slavers. He was promoted to a captaincy in 1841, and participated in the bombardment of Vera Cruz. On the breaking out of the civil war he was made flag-officer of the Atlantic blockading squadron, and the *Minnesota* was his flag-ship. He commanded the naval force which in connection with the land forces of Gen. Butler, captured Forts Hatteras and Clark. In 1862 he was retired as rear-admiral. In 1871 he became port-admiral of New York, and resided in Brooklyn at the time of his death.

STROBILA. See TAPE WORM.

STROMBIDÆ, a family of gasteropodous mollusks, of the order *pectinibranchiata*, nearly allied to *buccinidæ* (whelks, etc.) and *muricidæ*. The shell has a canal, the external lip of which, as it attains maturity, becomes more or less dilated, and is marked with a sinus, whence the head issues when the animal comes out. The foot is narrow and small, but is employed in active leaping movements, during which the shell oscillates from side to side. The species are numerous, and are mostly inhabitants of tropical seas. Some of them are among the largest of mollusks. *Strombus gigas* is the largest known univalve. It is found in the West Indies, on reefs in shallow water, and is fished both for the table and on account of the shell. Great numbers of the shells are imported into Britain; 300,000 have been brought to Liverpool in a year. They are sometimes called fountain-shell, from their occasional use as a garden ornament. Their chief use, however, is by cameo-makers, by whom they are valued for their solid and delicately tinted substance. A shell sometimes weighs four or five pounds. Pearls of a delicate pink color are sometimes found in this shell. The *strombi* are sometimes called wing-shells, from the dilated margin of the lip.

STROMBOLI, one of the group of the Lipari islands (q. v.), the most north-easterly of the group, is about 12 m. in circumference, circular in shape, and contains 2,000 inhabitants. It is wholly of volcanic formation, and rises to the height of 3,038 ft. above sea-level. On its western side is a volcano of considerable activity. Sulphur and pumice-stone are gathered in large quantities, and among the chief agricultural products are cotton, wine, and excellent fruits.

STROM NESS. See ORKNEY ISLANDS.

STRONG, GEORGE C., 1832-63; b. Vt.; graduated at West Point, 1857, and held the position of 1st capt. of cadets there for 3 years. In 1861 he was attached to the staff of Gen. McDowell and acted as his aide at the battle of Bull Run. He afterward served with McClellan and Butler, and distinguished himself at Biloxi, Tangipahoa river, and in the assault on Fort Wagner, where he was fatally wounded. He rose to the rank of capt. of ordnance and brig.-gen. of vols. Gen. Strong was the author of *Cadet Life at West Point* (Boston, 1862).

STRONG, JAMES, S.T.D., b. New York, 1822; graduated at Wesleyan university, Middletown, Conn., 1844; settled at Flushing, L. I., and taught Hebrew and Greek to private pupils; received, though a layman, the degree of S.T.D. from Wesleyan university, 1856; professor of biblical literature and acting president of Troy university, 1858-61; professor of exegetical theology in Drew theological seminary, Madison, N. J., 1868; traveled in the east, 1874. In 1853 he became associated with the Rev. Dr. John McClintock in the preparation of the *Cyclopædia of Biblical, Theological, and Ecclesiastical Literature*, he having the department of biblical literature. After the death of Dr. McClintock he became the chief editor. He has published also *Harmony and Exposition of the Gospels*; *Greek Harmony of the Gospels*; *Manuals of Greek and Hebrew Grammar*; *Outlines of Theology*; *Appeal to Sunday-school Efforts*; also, articles in the *Methodist Quarterly Review* and *Christian Advocate and Journal*. He prepared the translation of the Book of Daniel for Lange's commentary, and was a member of the Anglo-American committee on the revision of the Bible. He died in 1894.

STRONG, JAMES H., b. Canandaigua, N. Y., 1814; son of Judge Elisha B.; entered the navy as midshipman, 1829; served in the Mexican war; commander, 1861; capt., 1865. He commanded the steamer *Mohawk*, 1861; the *Flag*, 1862; and the steam sloop *Monongahela*, 1863-65. In 1863 he transported a division of the secret expedition of Gen. Banks's army to Brazos, and aided the troops in taking the battery at Arkansas pass. He was in command of the *Monongahela* during her engagement with the ram *Tennessee* in the battle of Mobile Bay; commodore, 1870; rear admiral, 1873. D. 1882.

STRONG, NATHAN, D.D., 1748-1816; b. Conn.; graduated at Yale college, 1769; tutor there, 1772; ordained pastor of First Church (Congregational), Hartford, 1774, where he remained till his death; was a chaplain in the army in the revolutionary war. He published *The Doctrine of Eternal Misery Consistent with the Infinite Benevolence of God*; *Sermons*, 2 vols; *The Hartford Selection of Hymns*. He originated and edited the *Connecticut Magazine*, and was principal founder of the Connecticut missionary society. He held a high rank for learning and usefulness, and was noted for shrewdness and wit.

STRONG, THEODORE, LL.D., 1790-1869; b. Mass.; graduated at Yale in 1812, taking the mathematical prize; tutor in mathematics at Hamilton college, 1812-16; professor of mathematics at Hamilton, 1816-27. A new geometrical demonstration by him of the values of sines and co-sines of the sum and difference of two arcs, and a solution of a difficult problem in diophantine analysis, were published in the *American Journal of Science* in 1818. Other important papers appeared in subsequent numbers. After having mastered the *Principia* of Newton and the subjects added by its commentators, he addressed himself to the study of the more modern analysis of La Grange and Laplace. This required a knowledge of the French language which he did not possess, but he soon taught himself sufficient to be able to read mathematical works in French as well as in English or Latin. In 1827, upon a second invitation from Rutgers

college, N. J., he became professor of mathematics and natural philosophy in that institution, and removed to New Brunswick, where he remained during the rest of his life, performing the duties of his chair till 1862. Prof. Strong made many important contributions to mathematical science, among which may be mentioned the solution of what is known as the irreducible case of cubic equations of Cardan, a result which had long been sought in vain. He also devised a method for the application of the binomial theorem for the extraction of the roots of whole numbers. His two principal systematic works are: *A Treatise on Elementary and Higher Algebra* (1859); and *A Treatise on the Differential and Integral Calculus* (1869). Both of these treatises contain much original work. The work on Calculus, written in his 78th year, and without the aid of notes or books, has many original features, and is divested of technicalities and formulas which have become the accretions of time. It contains a solution, by a new and beautiful method, of the problem, "To find the area bounded by the ordinate of a plane curve drawn through the origin of the co-ordinates by any other ordinate and the intercepted parts of the axis and the curve, supposing the ordinates to be constantly positive between the preceding limits." Prof. Strong was a contributor to various mathematical and scientific journals for the greater part of his life. To the *American Journal of Science* he contributed 22 papers between 1818 and 1845. To the *Mathematical Diary*, published at New York and edited at first by Dr. Robert Adrian and afterward by James Ryan, he also contributed. To the *Mathematical Miscellany*, edited by Mr. Charles Gill at Flushing, L. I., he contributed 22 papers; to the *Cambridge Miscellany*, edited by Profs. Peirce and Lovering, seven papers; and to the *Mathematical Monthly*, edited by I. D. Runkle, two papers. He also communicated five different papers to the National academy of sciences from 1864 to 1867 inclusive. Among the papers contributed to the *American Journal of Science* are a systematic discussion of the laws regulating the action of a central force, the path of the curve produced thereby, and the mutual action of a system of bodies; a discussion of the parallelogram of forces, their composition and resolution, and the statical equilibrium. In volume xvi. of the journal, on p. 286, there is a deduction of the differential equation which constitutes the fundamental formula for expressing the angular velocity of a planet in terms of its radius vector, and thence, the force being given, the law of the curve of revolution, and of all curves produced by a central force, corresponding to the result given by Laplace in the first part of his second book of the *Mécanique Céleste*, and to that of Newton in the 41st proposition, section viii., of the *Principia*. He was one of the original members of the National Academy of Science, and was also a member of the Connecticut Academy of Arts and Sciences at New Haven, of the American Academy of Arts and Sciences at Boston, and of the American Philosophical Society at Philadelphia.

STRONG, WILLIAM, LL.D., b. Conn., 1808; graduated at Yale college, 1828. He studied law, and after his admission to the bar, 1832, began practice in Reading, Penn. In 1849 he was elected to congress and served two terms, after which he resumed practice. In 1855 he was elected a judge of the Penn. supreme court, but resigned in 1868. After two years of practice in the higher branches of the profession, he was appointed associate justice of the U. S. supreme court by Pres. Grant, retiring in 1880. He died at Lake Minnewaska, N. Y., Aug. 19, 1895.

STRONG, WILLIAM L., mayor of New York, born in Richland co., Ohio, March 22, 1827. At the age of sixteen he entered a dry-goods house in Wooster, Ohio, and in 1853 came to New York City, entering the employment of L. C. Wilson and Co. The following year he became connected with Farmham, Dale and Co., which after numerous changes in the firm dissolved partnership, in Dec., 1869, and was succeeded by W. L. Strong and Co. Mr. Strong was for many years a director of the Central National Bank and its president since 1887; a director of the Erie Railway Co., the N. Y. Life Insurance Co., the Mercantile Trust Co. and other corporations. He is a member of the Union League Club, president of the Ohio society and member of the Downtown, Merchants', Colonial, Republican and other clubs. On Nov. 6, 1894, he was elected mayor of New York on a fusion ticket, defeating the Tammany nominee by a large majority. His three years' term of office was marked by its strictly non-partisan character.

STRONGYLIDÆ, a family of nematode worms, possessing the following common characters: The body is round, and sometimes very much elongated, and almost thread-like. The mouth is round, oval, or triangular, and situated at the extreme anterior end of the body. The tail of the male is commonly furnished with a bursa, usually emitting two spicules. The whole family is parasitic, and contains a number of genera. Some of the strongylidæ are parasitic in man, some in mammals, birds, reptiles, etc.

STRONGYLUS (from the similar Greek word signifying *round*) is the term applied to a genus of the family *strongylidæ* (q.v.) of nematode parasitic worms. The only true strongylus infesting man is the *S. bronchialis* of Cobbold, previously known as *filaria hominis bronchialis*, *hamularia compressa*, etc. The male usually measures rather more than half an inch, while the female is upward of an inch in length. For the general and specific characters of this rare entozoon, the reader is referred to Cobbold's *Entozoa*, p. 357. The worm was originally discovered by Treutter in 1790, who found several

individuals in the bronchial glands of an emaciated subject. In 1845 it was again found by Dr. Fortsitz at Klausenberg in Transylvania, in the lungs of a boy six years old. These are the only two cases recorded by Küchenmeister and Cobbold of its occurring in the human subject; but closely-allied species, *S. paradoxus* and *S. micrurus*, are occasionally found, according to Cobbold, in the lungs and air-passages of the pig and the calf respectively, and Küchenmeister states that he has found a species in the lungs of the sheep.

Closely allied to strongylus is the genus *eustrongylus* of Diesing and Cobbold, which contains the species *E. gigas*, more commonly known as the *strongylus gigas* of Rudolphe, Cuvier, and others. This is the largest nematode worm at present known to infest man or any other animal; "the male measuring from ten inches to a foot in length, and $\frac{1}{4}$ of an inch in breadth; while the female is said to attain a length of over 3 feet, its transverse diameter being fully half an inch; body cylindrical, and more or less tinged with redness; head obtuse, and furnished with a simple oval aperture surrounded by six chitinous nodules: mode of reproduction, probably viviparous; eggs broadly oval, measuring about $\frac{1}{16}$ " from pole to pole."—*Op. cit.*, p. 358. This worm occurs, according to Bremser, in the kidneys and bladder, sometimes in the abdominal cavity and the omentum, more rarely in the lungs and liver of "martens, dogs, wolves, seals, otters, oxen, and horses." Fortunately it is very rare in man, and, according to Cobbold, weasels are the animals in which it is most commonly found. The symptoms to which it must give rise must be much the same as those arising from abscess and degeneration of one of the kidneys, or from renal calculi. The diagnosis in a suspected case could only be established by the detection of the eggs or embryos in the urine.

STRONSAY, one of the Orkney islands, lies 15 m. n.e. from the town of Kirkwall. It is $7\frac{1}{2}$ m. long, and 6 m. in extreme breadth. Pop., 1274.

STRONTIA. See STRONTIUM.

STRONTIUM (symb. Sr, equiv. 43.8—new system, 87.2—sp. gr. 2.54) is a ductile and malleable metal, somewhat harder than lead, and of a pale yellow color. When heated in the air, it burns with a crimson flame, and becomes converted into its oxide, strontia. It is unaffected by the action of dry air, but it decomposes water at an ordinary temperature, hydrogen being explosively developed; and it burns in chlorine gas, and in the vapor of iodine, bromine, and sulphur. It dissolves in dilute nitric acid, but the strong acid has scarcely any effect on it. This metal does not occur in the native state, but exists as a carbonate in the mineral *strontianite* (so called from its being first found near Strontian, in Argyshire), and as a sulphate in the mineral known as *celestine* (so called from its delicate blue tint). It is obtained by the voltaic decomposition of the chloride of strontium. This metal bears to barium the same close relation that sodium bears to potassium; and the compounds of strontium resemble those of barium not only in their composition but in their properties.

The oxide of strontium, commonly known as STRONTIA, is obtained in the same way, and resembles in almost all respects the corresponding oxide of barium, except that it is inert when taken into the system, while baryta is poisonous. When a small quantity of water is poured upon it, it slakes, giving out heat.

The salts of strontia resemble those of baryta in their general characters, and in their being precipitated from their solutions by sulphuric acid and the soluble sulphates; but they differ from them in not being thrown down by silico-fluoric acid or hyposulphite of soda, and in their communicating to the flame of the spirit-lamp and to burning substances generally, a brilliant purple-red color. The salts of strontia occur only in the mineral kingdom, and are never found as normal ingredients of organic bodies. *Carbonate of strontia*, SrCO_3 , occurs native both in a massive and crystalline form, and may be obtained artificially as a white powder by precipitating a soluble salt of strontium with carbonate of soda. *Sulphate of strontia* occurs native in *celestine*, a mineral which is found in beautiful rhombic prisms in Sicily. *Nitrate of strontia*, $\text{Sr(NO}_3)_2$, separates from a hot concentrated solution in large colorless transparent anhydrous octahedral crystals, which dissolve freely in water. By the addition of nitric acid, it is precipitated from its aqueous solution. This salt is insoluble in alcohol; but when finely powdered, and mixed with it, it communicates to the alcoholic flame a beautiful red or crimson color. In consequence of this property, it is employed by the makers of fireworks. A mixture of 40 parts of nitrate of strontia with 10 of chlorate of potash, 13 of sulphur, and 4 of sulphide of antimony, deflagrates with a magnificent red color, and constitutes what is popularly known as *red Bengal fire*; but the mixture is dangerous both to prepare and to preserve, having more than once been the occasion of frightful accidents to the manufacturers from its becoming ignited spontaneously.

The most important of the haloid salts of strontium is the *chloride*, SrCl_2 , which may be obtained in crystals containing six equivalents of water. The water is expelled at a moderate heat, leaving the chloride anhydrous. The chloride is the only salt from which the metal has hitherto been obtained.

Regarding the history of this metal, it may be observed that strontia was discovered as an independent substance almost simultaneously by Hope and Klaproth in 1793. In 1807 Davy obtained barium and strontium from their oxides, but not in a pure state:

and it was not till 1855 that Bunsen and Matthiessen succeeded in procuring perfectly pure specimens of the metal.

STROPHULUS. See RED GUM.

STROSSMAYER, JOSEPH GEORGE, b. Eszek, 1815. After being educated at Pesth, Vienna, and Padua, he became Roman Catholic bishop of the united sees of Bosnia and Sirmia in 1850. He attended the Vatican Council of 1869, and the text of a violent speech, opposed to the introduction of the question of papal infallibility, was published in several journals as having been made by Bishop Strossmayer. In 1872, however, he wrote a letter to the *Français*, in which he denied having made such a speech. He retired from his see in 1891.

STROTH'ER, DAVID HUNTER, b. Va., 1816; came to New York in 1845 and studied art for several years. In 1853 he first became known to the public as "Porte Crayon," the author of a series of very amusing papers illustrative of travel, scenery, and manners in the south and elsewhere, some of which were afterward collected in *Virginia Illustrated* (1857). He entered the union army as capt. in 1861, became colonel, resigned in 1864, and in 1865 was brevetted brig.-gen. After the war he published in *Harper's Monthly* (where all his writings had appeared) a series of *Personal Reminiscences of the War*. He was consul-general to Mexico, 1879-85. He d. 1888.

STROUD, a market t. of Gloucestershire, 9 m. s.e. of the city of Gloucester, stands in a beautiful and extensive valley, at the confluence of the Frome and Slade, which unite to form the Stroudwater or Frome. It is the center of the woolen manufactures of Gloucestershire, and contains a number of woolen and silk-mills. The water of the Frome is peculiarly adapted for use in dyeing scarlet and other grain colors; and on this account cloth-factories and dyeworks have been built along its banks for the distance of 20 miles. Pop. '91, 9818.

STROUSBERG, BETHEL HENRY (DR.), b. Prussia, 1823; of Jewish parentage; original name Baruch Hirsch Strausbergi; in early life converted to Christianity; entered the office of his uncles, commission merchants, in London, 1835; married an English-woman; failed in the insurance business in 1847; became a teacher of languages in New Orleans, 1848; speculated in damaged goods to such advantage that he was able to return to London in 1849, and assist in publishing *The Chess Player* and other magazines. In 1855 he went to Berlin on insurance business, and negotiated for the East Prussian railway. He became a railroad magnate, building railroads in Germany, Hungary, and Roumania, and owning immense factories for manufacturing railroad materials. He established beet-sugar and porcelain factories, and was the proprietor of the Berlin cattle yard, the citadel grounds at Antwerp, and an immense estate in Bohemia. He engaged in vast speculations, employed 100,000 persons at one time, and was pointed out in Berlin as *Der Wunderdoctor*. In the war of 1870-71 he met with enormous losses; failed in 1875 in consequence of some transactions with the Roumanian government, and was imprisoned at Moscow for certain irregularities connected with a bank. He d. 1884.

STRUCK JURY. See SPECIAL JURY.

STRUENSEE, JOHANN FRIEDRICH, Count of, a man who, in the 18th century, attracted the attention and excited the sympathy of the whole of Europe, by his elevation and downfall at the Danish court. Struensee was born Aug. 5, 1737, at Halle on the Saale, where his father, Adam Struensee, the author of the old Halle Hymn-book, was pastor of the Ulrichskirche. Young Struensee studied medicine, and when scarcely 19 years old passed as doctor. Early alienated from positive Christianity, he zealously embraced the philosophy which had then arisen in France, and became a disciple of Helvetius and Voltaire. When his father removed to Altona he accompanied him, and was soon afterward appointed traveling physician to the young king, Christian VII. of Denmark; and on their return from a tour, physician in ordinary. At first the young queen, Caroline Matilda, sister of George III. of England, looked upon him with mistrust; and it was not till 1770, when Struensee successfully managed the inoculation of the two-year old crown-prince, afterward king Frederick VI., that she came round to him, intrusted him with the education of the prince, and by degrees made him the confidant of her unhappy position. Struensee removed the estrangement between the royal pair, which was the work of the favorite Holck, and, in consequence, rose still higher in favor with both. He was appointed reader to the king, and private secretary to the queen. Since the revolution of 1660, Denmark had been under the domination of the nobility, who, as a council of state, governed the country. Struensee saw the disadvantages of this government of the nobles, and formed the ambitious resolve to come forward in this land of his adoption as an enlightened reformer after the model of Frederick II. To begin with, he effected the downfall of the favorite Holck, in whose stead his friend Brandt was appointed royal companion and director of the court amusements. In order to gain the love of the people, Struensee proclaimed the freedom of the press. The council was dissolved, and a proclamation issued to the effect that the royal power in all its purity, as it had been handed down from olden times, was to be re-established. These measures amounted in reality to a revolution, and to a declaration of war against the aristocracy. The queen and Struensee, in whose hands the whole power now was, chose new ministers, and excluded

the feeble Christian entirely from the management of affairs. In July, 1771, Struensee received the title of cabinet minister, along with unlimited power. He brought several men from Germany, whom he appointed to different offices. This introduction of strangers caused great dissatisfaction among the people. In opposition to the politics of his predecessors, Struensee endeavored to free Denmark from Russian influence, and to find a natural ally in Sweden. The changes which he undertook in the internal affairs were directed to the advancement of the prosperity of the country, of civil liberty, and enlightenment. He put the finances in order, reduced the expenditure, loosened the fetters in which industry and trade had been bound, encouraged education, mitigated the penal laws, and brought order into the administration. An act passed in 1771 to a certain extent abolished serfage. All these reforms, which are still in operation in the Danish dominions, were excellent; but the haste and want of statesmanlike skill with which they were carried out made them appear as the acts of the most vexatious tyranny. Struensee committed a great mistake, too, in recklessly obtruding his philosophy of enlightenment in the face of the strict orthodox clergy and the pious prejudices of the people.

Struensee had scarcely been in power a year when the symptoms of reaction appeared in all quarters. The queen gave birth to a daughter in 1771, which, in the condition of the king, gave rise to most scandalous reports. The British ambassador, lord Keith, who saw the catastrophe approaching, proposed to Struensee, by advice of George III., to take refuge in England; but Struensee declined doing so. At the head of the hostile party was Christian VII.'s step-mother, Juliana Maria, princess of Braunschweig-Wolfenbüttel, who was impatient of the domination of the queen and Struensee. A bold stroke was to precipitate Struensee and ruin the queen, and the night when a court ball was to take place was fixed upon for carrying out the plot. The conspirators assembled at the king's stepmother's, and by a secret door entered the bedroom of the king, and obliged him to make out 15 warrants of arrest, among others for Struensee. Christian was prevailed upon, but with much difficulty, to write out orders to arrest and convey his consort the queen to Kronenburg. Struensee and the queen were then taken prisoners, and the former was treated with extreme harshness, put in chains, and brought to the citadel. He was accused of an assault on the person of the king; of the intention to compel Christian to abdicate the throne; of criminal intercourse with the queen; of using a fatal system in the education of the crown-prince; and of the usurpation and abuse of supreme power. Not one of these points could be legally proved. Struensee was, however, found guilty of a great and capital crime, and was sentenced to a cruel death. It was wished by some to proceed further against the queen; but the commissioners were satisfied with the simple separation of the royal pair, especially as the British ambassador threatened the appearance of a British fleet. After the king had confirmed the sentence, not without being urged by the Russian ambassador, it was carried into execution, April 28, 1772, amid the rejoicings of the multitude. In the prospect of death, Struensee is said to have returned to the Christian faith. There is no doubt that he did not deserve his fate, but that he fell a sacrifice to the party of the nobles. The execution of his friend Brandt, which took place at the same time, was a still clearer case of legal murder, as he never took any part in the affairs of government. Struensee's brother would have shared his fate had not Frederick II. claimed him as a Prussian subject. Queen Caroline Matilda left Denmark in May, 1772, and died of grief in 1775, in the castle of Celle in Hanover.

In recent times Struensee's history has been recalled to memory in a tragedy by Mich. Beer and Heinr. Laube. See Höst, *Count Struensee and his Ministry* (1824; Germ. Copenh. 1826); Falkenköld, *Mémoires* (Paris, 1826).

STRUTT, JOHN WILLIAM, third Baron Rayleigh, a distinguished physicist, born in England, Nov. 12, 1842. He was educated at Trinity college, Cambridge, graduated in 1865, as senior wrangler in the mathematical tripos, and became a fellow of the college in 1866. He succeeded to the title in 1873. He was professor of experimental physics in the university of Cambridge, during 1879-84, and professor of natural philosophy in the Royal Institute of London since 1887. He has been a fellow of the Royal Society since 1873, president of the British Association (section A) since 1882, member of numerous other scientific societies, and a correspondent of the Institute of France. In 1894, he discovered, in conjunction with Prof. Ramsay, a new element, present in the atmosphere, which he has since prepared in quantity and has named *Argon*. For this discovery he received from Columbia college, on recommendation of the National academy of sciences, the Barnard medal "for meritorious service to science." He is the author of many valuable papers on "Optics," (in *Philosophical Magazine*, 1871-72), on "Resonance" (*Philosophical Transactions*, 1871); *The Theory of Sound*, (2 vols., 1877-78), and many other papers in scientific journals.

STRUTT, JOSEPH, 1742-1802; b. England; studied painting, but afterward devoted himself to antiquarian researches. Among his works are *The Regal and Ecclesiastical Antiquities of England* (1773); *The Chronicle of England* (1777-78); *Complete View of the Dress and Habits of the People of England from the Establishment of the Saxons in Britain to the Present Time* (1796-99); and *The Sports and Pastimes of the People of England* (1830).

STRUVE, FRIEDRICH-GEORG-WILHELM, a celebrated astronomer, was b. at Altona, April 15, 1793, educated at the university of Dorpat (Russia), and appointed to a post in the observatory of that place in 1813. He became director of the Dorpat

Observatory in 1817, and continued with the utmost assiduity his observations and researches respecting double and multiple stars, adding immensely to our knowledge of these systems; and earning for himself the reputation of being one of the most skillful of practical astronomers. The instrument with which he observed was a Fraunhofer's (q.v.) refractor, of 10 in. aperture, and $13\frac{1}{2}$ ft. focal length; and with this telescope, in gleaning from the depths of space the materials for his three important works on double stars (1822 and 1828, 1837 and 1840, 1852), he examined no fewer than 120,000 of these twinkling luminaries. His investigations have led him to the conclusion, that the number of true double stars is much larger than was previously supposed (see STARS). Struve also executed a number of important geodetic operations, such as the triangulation of Livonia, in 1816-19, and the measurement of an arc of the meridian in the Baltic Provinces, in 1822-27; which was subsequently (1828-56) extended by him in conjunction with Hansteen (q.v.) and Selander, to the North Cape; and by Gen. Tenner southward to Ismail in Turkey. This latter undertaking, the most extensive trigonometrical operation ever performed, when completed, gave the length of a meridian arc of 20° , and enabled geometers to determine with increased accuracy the exact form of the earth. Meanwhile, Struve had been appointed, in 1839, director of the best organized observatory in the world, that of Pulkova (q.v.), and also chosen *correspondant* in the astronomical section of the Academy of Sciences of Paris. He died at St. Petersburg Nov. 23, 1864.—His son, OTTO WILHELM STRUVE, also an eminent astronomer, was born at Dorpat, May 7, 1819, was educated under his father's direction, became his chief assistant at Pulkova, and the director of the observatory after his death. He has made numerous astronomical discoveries, among which are more than 500 new double stars, and (1847) a satellite of Uranus, and has written numerous important papers, the most noticeable of which set forth his researches on the inner or dusky ring, and on the variation in breadth of the bright rings of Saturn, and on the periodic motions of double stars. He published 14 volumes of *Observations de Poulkova* (1869-93).

STRYCHNIA, or STRYCHNINE. See NUX VOMICA.

STRYCHNOS, a genus of trees of the natural order *loganiaceæ*, having a five-lobed calyx, a tubular funnel-shaped or salver-shaped corolla, with a five-partite limb, five stamens, a filiform style, numerous ovules, and a one-celled berry, with a leathery rind, many-seeded, or, by abortion, one-seeded, the seeds discoidal and compressed. To this genus belongs the *S. nux vomica*, a tree of middling size, with ovate-stalked leaves, a native of India, the fruit of which is produced in great abundance, and is about the size of a small orange; the seeds are the *nux vomica* of commerce, and yield *strychnine*. The bark partakes of the poisonous quality of the seeds. The wood of the tree is very hard and durable. The clearing-nut (q.v.), and St. Ignatius' (q.v.) bean are produced by species of this genus, to which also belongs the tree (*S. toxifera*) which produces the woorial or curare (q.v.) poison of South America. Another species is the UPAS TIEUTÉ (*S. Tieute*) of Java, a large climbing shrub, the bark of which is extremely poisonous, containing a very large quantity of strychnine. The wood of a species found in the north of India (*S. colubrina*), which is also a climber, is an imaginary cure for snake-bites. The bark of *S. pseudo-quina*, a Brazilian species, is used as a substitute for cinchona.

STRYPE, Rev. JOHN, a voluminous ecclesiastical historian, was b. in London in 1643. He studied at Cambridge, entered the church, and held for many years, with other smaller livings, the rectory of Low Leyton, in Essex. He died at Hackney in 1737, having reached the great age of 94. His works fill thirteen large folio volumes. The most important are—*Memorials of Archbishop Cranmer* (1694); *Life of Sir Thomas Smith, secretary of state to Edward VI. and Elizabeth* (1698); *Lives of Bishop Aylmer* (1701), *Sir John Cheke* (1705), *Archbishop Grindal* (1710), *Archbishop Parker* (1711), and *Archbishop Whitgift* (1718); *Annals of the Reformation* (vol. i. 1709, vol. ii. 1723, vol. iii. 1728, and vol. iv. 1731); *Ecclesiastical Memorials*, relating to religion and the church of England under Henry VIII., Edward VI., and queen Mary, in 3 vols. folio, published in 1721. This is his best work, forming, with Burnet's more readable *History of the Reformation*, a consecutive and full account of the reformed Anglican church. Strype also published an enlarged edition of Stow's *Survey of London*, with several sermons and pamphlets. As a writer, he is heavy, but honest and plodding, and he was a faithful transcriber of the ancient papers he published, which, he says, were all copied with his own hand.

STUART, Lady ARABELLA, or ARBELLA, 1575-1615, b. England; daughter of Charles Stuart, earl of Lennox, and cousin of James I. Her relationship to Elizabeth gave rise to a number of plots to put her on the throne. Several schemes to marry her were defeated by Elizabeth. In 1603 sir Walter Raleigh was charged with a plot to place her on the throne. In 1610 it was discovered that she had made a secret marriage with William Seymour, grandson of the earl of Hertford. Seymour was imprisoned in the Tower, and she was put in the custody of the bishop of Durham, but escaped to a French vessel, in which her husband, who had escaped from the Tower, was also to sail. He did not reach it, and it sailed and was captured. He escaped, however, in another vessel. Arabella spent the rest of her life in the Tower, and finally became insane.

STUART, CHARLES EDWARD LEWIS CASIMIR, often called the younger pretender, the eldest son of James Francis Edward, prince of Wales, known as the elder pretender, or chevalier St. George (see **STEWART, FAMILY OF**), and his wife Clementina Sobieski granddaughter of the celebrated Polish monarch, John Sobieski. He was born at Rome on Dec. 31, 1720, and bore among the Jacobites the title of Prince of Wales. He served under Don Carlos in Spain, and in his youth is described as having been handsome, affable, and engaging in manners. In 1743, 28 years after his father's unsuccessful attempt to regain the crown, a scheme was contrived in France, with the support of the Jacobites in England, by which Charles Edward was to recover the throne of Great Britain for his family. The first contrived project was to land an army in Kent, where were many adherents of the exiled house; and troops to the number of 15,000 were assembled, and transports provided at Boulogne, Dunkirk, and Calais to carry them to England. But the squadron which was to have convoyed the transports fled before the British fleet under sir John Norris; a storm destroyed the transports, and most of the troops were drowned. Charles, however, only awaited a favorable opportunity to make a fresh attempt. In July, 1745, when George II. was in Hanover, and Scotland almost without military, he sailed from Nantes, in company with the marquis of Tullibardine, and a few other devoted followers, and landed in the bay of Lochnanuagh, whence he proceeded to Kinlochmoidart, where the Highland clans attached to his cause were summoned to rise. Ten days later, Charles's standard was set up at Glenfinnan; and he marched southward at the head of a large body of hardy mountaineers. Government offered a reward of £30,000 for the apprehension of the pretender's son, who retaliated by offering a like reward for the apprehension of the elector of Hanover. At Perth, the insurgents were joined by the duke of Perth and lord Strathallan, with a numerous retinue of followers; and on their approach, Edinburgh surrendered without resistance, the castle, which was in possession of the king's troops, still holding out. Charles took up his residence at Holyrood Palace, where he proclaimed his father king of Great Britain, and himself regent.

Meanwhile, sir John Cope, the commander-in-chief of the king's troops in Scotland, having collected some re-enforcements in the n., came from Aberdeen to Dunbar by sea, and encamped at Prestonpans. He was there unexpectedly attacked by the Highlanders, and ignominiously routed, leaving baggage, cannon, and camp equipage on the field. Contrary to the advice of his council, Charles, who could not bear opposition, resolved to advance into England, though his force hardly exceeded 6,500 men. Carlisle surrendered at his approach, and he proceeded unmolested as far as Derby. In the mean time, three English armies, each larger than his own, were preparing to meet him. Being unable to raise any recruits in England, he found it necessary to retreat into Scotland, where he hoped to meet a re-enforcement under lord John Drummond. On their way n., the Highlanders were pursued by the duke of Cumberland, whom they defeated near Penrith. Finding that Edinburgh was now in possession of the king's troops, Charles, joined by lord John Drummond and lord Strathallan, made his way to Stirling. That town surrendered to him, and he laid siege to the castle. Gen. Hawley, in endeavoring to raise the siege, was utterly routed by lord George Murray, at the head of the Macdonalds of Keppoch. But the advance of the duke of Cumberland obliged the rebels to retreat further n., and for a time they carried on a desultory war with the king's troops in the neighborhood of Inverness. On April 16, 1746, the duke of Cumberland encountered Charles's army on Culloden Moor, and opened a heavy cannonade on them. The Highlanders at first rushed boldly forward; but on the advance of the royal infantry, they gave way; the battle soon became a rout, and the fugitives were pursued and slaughtered by the dragoons, who gave no quarter, and spread carnage and desolation over the country. The rebels lost that day at least 1000 men of the bravest and most devoted to the cause. Charles escaped to the Hebrides, hunted by the king's troops; disguised in female attire, he was conveyed to Skye in an open boat by Flora Macdonald, daughter of Macdonald of Milton. For months he wandered in concealment among the mountains of Skye and the mainland, where he had many hairbreadth escapes; and though his secret was known to hundreds of the poorest of the people, no one was tempted by the £30,000 reward to betray him. He eventually escaped to France, and no further attempts were made to reinstate the exiled family.

Charles Edward remained in France till the peace of Aix-la-Chapelle (1748). It was made a condition of that treaty that France should abandon the cause of the Stuarts; and Charles, refusing to quit France voluntarily, was conducted with a guard out of the kingdom, and retired to Rome.

He married on April 17, 1772, Louisa Maximiliana de Stolberg-Guedern, daughter of Gustavus Adolphus, prince of Stolberg-Guedern. The union did not prove a happy one, and the princess withdrew herself from him. See **ALBANY, COUNTESS OF**. In the latter years of his life, the prince was addicted to intoxication. When his claims ceased to be supported by any foreign power, he dropped the title of prince of Wales, and assumed that of count of Albany. He died at Rome, Jan. 31, 1788, and was buried at Frascati. There was no issue of his marriage, but he left a natural daughter, on whom he bestowed the title of duchess of Albany, and to whom he bequeathed considerable property.

Two brothers, generally known as John Sobieski Stuart and Charles Edward Stuart

endeavored, some years ago, to persuade the world that they were legitimate grandsons of Charles Edward. In point of fact, they were sons of Captain Thomas Allen, R.N., and grandsons of Admiral John Carter Allen, who died in 1800. Their story, as set forth, with some slight mystifications, in a work called *Tales of the Century, or Sketches of the Romance of History between the Years 1746 and 1846*, was to the effect that their father, in place of being Admiral Allen's son, was a son of prince Charles and the princess Louisa, whose birth was kept secret, from fear of the Hanoverian family, and who was intrusted to Admiral Allen, and passed off by him for his own son. The life of Charles Stuart is detailed in *History of the Rebellion, 1745-46*, by R. Chambers.

STUART, GILBERT CHARLES, American painter, was b. at Narragansett, Rhode Island, in 1755. In his boyhood, he went to Edinburgh with a Scotch painter named Alexander, with whom he studied his art; but his master dying, he worked his passage home, and began to paint portraits at Newport. In 1778 he made his way to London, where he led for two years a wild Bohemian life; but his talent was recognized by his countryman, Benjamin West, president of the Royal Academy, who took him into his family, and whose full-length portrait he painted for the National Gallery. In 1781 he opened his studio in London, and painted the portraits of his majesty George III., H.R.H. the prince of Wales, the duke of Northumberland, sir Joshua Reynolds, John Kemble, col. Barré, and many other celebrated characters. He also made a professional visit to Dublin, and in Paris painted a portrait of Louis XVI. In 1793 in the fullness of his powers and fame, he returned to America, and painted portraits of Washington, Jefferson, and many of the distinguished men of the period, and commenced a portrait of John Quincy Adams, which at his death was finished by Sully. He died at Boston, July, 1828.

STUART, JAMES EWELL BROWN, 1833-64; b. Va.; graduated at the U. S. academy, West Point, 1854. He was engaged on the frontier fighting Indians, under Sumner and Joseph E. Johnston, and became noted for his daring. In 1857 he was severely wounded while fighting a party of Cheyennes. In May, 1861, President Lincoln appointed him a capt. in the U. S. cavalry, but he declined the appointment to accept from the confederates that of col. of a Virginia cavalry regiment. He commanded the confederate cavalry at the first battle of Bull Run; and in September was appointed brig.gen., and given command of all the Virginia cavalry. He made several successful raids on the union positions, and was appointed maj.gen. in the confederate army, and placed in command of a division of cavalry. On Aug. 22, 1862, he made his famous dash at the right flank of Gen. Pope's army, at Catlett's station. During a heavy storm he penetrated to Pope's headquarters, where he succeeded in capturing important papers, besides obtaining the private effects and dress uniform of Gen. Pope, and of several of his officers. He made important raids after Antietam; in the Chancellorsville campaign; and during Lee's invasion of Pennsylvania; and covered the confederate retreat after the battle of Gettysburg. He was defeated by Sheridan's cavalry in the Wilderness; and on May 12, 1864, was mortally wounded in an engagement with them near Richmond; to which city he was taken, and where he died on the evening of the same day.

STUART, MOSES, American divine and author, was born at Wilton, Conn., Mar. 26, 1780, and educated at Yale, where he remained for some time as a tutor. He began the study of law, but abandoned it for theology; was ordained as pastor of a Congregational church at New Haven in 1806; and in 1809 was appointed professor of sacred literature at the theological school at Andover, a position he filled till 1848. During this period, in addition to his professorial duties, he wrote a *Grammar of the Hebrew Language*, without points; *Letters to the Rev. W. E. Channing*; *Hebrew Grammar*, with points (based on Gesenius); *Commentaries on the Epistle to the Hebrews*, and *the Epistle to the Romans*; on the books of *Ecclesiastes*, *Proverbs*, *Daniel*, and *the Apocalypse*; *Hebrew Chrestomathy*; *Essay on the Liquor Traffic*; *Essay on Christian Baptism*; *Hints on the Prophecies*; *Conscience and the Constitution*—manifesting in all acuteness, vigor, and versatility. Moses Stuart has been called the father of biblical science in this country. While his own contributions to it are of great value, he accomplished still more by the impulse which he gave to others. Studying the Hebrew language with enthusiasm, he infused the same spirit into his classes. He died at Andover, Mass., Jan. 4, 1852. His daughter Elizabeth married Rev. Austin Phelps, D.D., and was an author of considerable popularity. His grand-daughter, Elizabeth Stuart Phelps Ward, is widely known as an author.

STUBBS, THE RIGHT REV. WILLIAM, D.D., was born at Knaresborough, June 21, 1825; educated at the Grammar School, Ripon, and at Christ Church, Oxford, and elected to a Fellowship at Trinity College in 1848. He was ordained in 1848, was Diocesan Inspector of Schools in the diocese of Rochester till 1866, when he was appointed Regius Professor of Modern History at Oxford. In 1868 he was elected Curator of the Bodleian Library, and in 1872 was chosen a member of the Hebdomadal Council. In 1875 he was presented to the Rectory of Cholderton, Wilts, appointed Canon Residentiary of St. Paul's, 1879; consecrated Bishop of Chester in 1884, and Bishop of Oxford in 1889. He has published *Mosheim's Institutes of Church History* (1863); *Chronicles and Memorials of Richard I.* (1864-65); *Chronicle of Roger Hovedon* (1868-71); *Memorial of Walter of Coventry* (1872-73); *Memorials of St. Dunstan* (1874); *Select Charters and other Illustrations of English Constitutional History, from the Earliest Period to the Reign of Edward I.* (1870); and his most famous work, *The Constitutional History of England*, in three volumes (1874, 1875 and 1878).

STUCCO, a composition used for the finer parts of plaster-work, such as cornices, enrichments, etc. Gypsum (q. v.), or plaster of Paris, is used for this purpose. A coarser kind of stucco is also used for making floors, and for plastering the exterior of buildings. See *illus.*, SPAIN, Vol. XIII.

STUHLWEISSENBERG (Hung. *Székes Fejérvár*, Slav. *Bielhrad* or *Bialigrad*, Lat. *Alba Regalis* or *Alba Regia*), a royal free town of Hungary, and seat of a bishop, lies in a swampy plain in the neighborhood of the marshes of Sár-Rét, 16 m. n.e. of lake Balaton. The principal buildings are the splendid cathedral of the Virgin Mary, the church of St. John, and the bishop's palace. It has several Catholic schools, a military academy, and a theater; the principal square is adorned by a bronze statue of the Hungarian poet Vörösmarty. The inhabitants manufacture cotton cloths, flannels, leather, silk, and knives ("Stuhlweissenburg clasp-knives"), and extract soda from the swamps. Pop. '90, 27,548. Stuhlweissenburg is built on the site of the Roman *Floriana*, and from 1027 to 1527 was the place where the kings of Hungary were crowned and buried, 14 of whom repose here. In later times it suffered much from the ravages of war, and was for some years in the hands of the Turks.

STUMPF, KARL, psychologist, b. at Wiesentheid, Bavaria, April 21, 1848; studied at the universities of Würzburg and Göttingen, and was professor of philosophy successively at Würzburg (1873), Prague (1879), Munich (1889), and Berlin (1894). He is a member of the Prussian academy of sciences, and is the author of *Ueber das Verhältnis des Platonischen Gottes zur Idee des Guten* (1869); *Ueber den psychologischen Ursprung der Raumvorstellung* (1873), *Tompsychologie* (1885-90) and *Psychologie und Erkenntnistheorie* (1891).

STUNDISTS, Protestant sect, mostly of Russians from the Eastern church, formed in 1817 by colonists of Württemberg, and now numbering over a million adherents. Its formulas closely resemble those of the Anabaptists; it repudiates the sacraments, and demands an equal distribution of property.

STURDY, or the *Gid*, affects sheep, and occasionally cattle, and is caused by the presence within the brain of a hydatid, reaching sometimes the size of a hazel-nut, and floating in a watery fluid inclosed in a membranous sac. This hydatid, when given to dogs, is known to produce tape-worms, and conversely itself originates from the ova of the tape-worm ejected on the pastures by dogs, rabbits, or even by sheep themselves. In the state of ova, or in some of its earlier minuter transitional forms, the hydatid embryo is picked up along with the grass, passes into the blood, and is thence laid down in the soft loose textures of the brain. It is most common in low damp pastures, and amongst sheep from six to twenty months old. The animal cannot properly seek its food, loses condition, staggers when moved, turns stupidly round almost in one spot, and usually toward the side on which the hydatid lies. The parasite and its sac may generally be safely removed by placing the sheep, with its feet tied, on a table or bench, searching for the softened portion of the skull, which generally overlies the hydatid, laying back a flap of skin, and introducing the trochar and canula, and when the sac is deep-seated, cautiously withdrawing it with the help of a small syringe. Protected by a leather cap and simple water-dressings, the wound speedily heals.

STURGEON, *Accipenser*, a Linnæan genus of cartilaginous fishes, now forming the family *sturioidæ*, and placed by Müller in the order of *ganoids*, distinguished by the ganoid (q. v.) scales or bony shields which form the external covering. The gills are free, as in the osseous fishes. The vertebral column is soft; and there are no evident sutures in the skull. Reproduction is by roe, as in osseous fishes. The form of sturgeons is elongated and angular; the plates are arranged in regular rows; the head is cuirassed; the snout long and conical; the mouth is on the under surface of the head, tubular, protractile, and without teeth. The upper lobe of the tail is much larger than the under. The dorsal and anal fins are opposite to one another, behind the ventrals. The air-bladder is very large, and communicates with the gullet by a large hole. The species of sturgeon are numerous, and inhabit both the sea and fresh water, ascending deep muddy rivers at certain seasons, and temporarily inhabiting lakes. Numerous species are found in the northern parts of the world, although there are none in the Arctic ocean, or the rivers which flow into it, but the s. of Siberia and North America particularly abound in them. They are plentiful in the Caspian and Black seas, and in the rivers connected with them, where the sturgeon fishery is of great importance, supplying the inhabitants of large districts with their chief article of subsistence, and producing great quantities of caviare (q. v.), or preserved sturgeon roe, and of isinglass (see *GELATINE*), for sale. The COMMON STURGEON (*A. sturio*) is sometimes caught in the mouths of British rivers, most frequently in salmon-nets; and is a large fish, 6 or 8 ft. in length, with five rows of flattened plates; the muzzle long and pointed. Another species (*A. latirostris*), with broader muzzle, also visits the British coasts, but they are not popularly distinguished. The sturgeon is more abundant on the northern coast of Europe. It is also found in the more southern parts, and was in very high repute for the table among the Greeks and Romans. At their banquets it was introduced with particular ceremonies. In England, when caught in the Thames, within the jurisdiction of the lord mayor of London, it is a *royal* fish, reserved for the sovereign. Its flesh is white, delicate, and firm. It is used both fresh, generally stewed, and pickled or salted.—The

largest species of sturgeon is the **BIELAGA**, or *Иuso* (*A. Iuso*) of the Black and Caspian seas, and their rivers. It attains the length of 20 or 25 ft., and has been known to weigh nearly 3,000 lbs. It enters the rivers in winter, while they are still covered with ice. Great part of the caviare of commerce is made from it, and much isinglass, which is merely the air-bladder washed, cut into strips and dried. The **STERLET** (*A. Ruthenus*) is a comparatively small species, only about 3 ft. in length, found in the same regions, and particularly esteemed for the delicacy of its flesh, and of the caviare obtained from it. There are several other European and Asiatic species; and some of the North American rivers and lakes abound at certain seasons in species of sturgeon which are peculiar to them.—Sturgeons spawn in fresh water, but the young are seldom seen there, and are supposed to descend very early to the sea.

STURGIS, SAMUEL DAVIS, b. Penn., 1822; graduate of West Point, 1846; served through the Mexican war; taken prisoner during the operations before Buena Vista; exchanged after a short confinement. He was on duty in California, New Mexico, and the w. frontier; capt., 1855. In the war of the secession he was obliged to abandon fort Smith, Arkansas (his officers having resigned to join the confederate army), taking with him his command and saving the government property. As maj. 4th cavalry, 1861, he served under Lyon, and succeeded to his command at Wilson's Creek. In 1862 he was assigned to the command of the fortifications at Washington. He was prominent at South mountain, Antietam, Fredericksburg, and in the operations in Kentucky and Ohio, 1863-64, joining in the expedition against Gen. Forrest; col. 7th cavalry, 1869. He had been brevetted maj.-gen., 1865. In 1886 he retired from active service.

STURT, Sir CHARLES, 1806-69; b. England; entered the British army, and in 1825 was stationed in New South Wales, then holding the rank of capt. In 1828 he headed an exploring expedition which penetrated the interior of Australia and discovered the Macquarie, Castlereagh, and Darling rivers, and in 1830, the Murray river, which he descended to Lake Alexandrina. Another expedition in 1844 reached the desert in the center of the continent. For these explorations he was honored with high colonial positions and on his return to England was knighted. He published two books describing his explorations.

STURTEVANT, JULIAN MONSON, b. Conn., 1805; became professor of mathematics in Illinois college, and in 1844 was elected its president, resigning the position about 1880. He published about 1862 *The Present Attitude of England toward the United States*, and also wrote *Economics; The Keys of Sect*, and contributed to many religious periodicals. He was original and vigorous as a thinker. He d. 1886.

STUTSMAN, a co. in N. Dakota, drained by the Dakota river and Pipe-stem creek; 2304 sq. m.; pop. '90, 5266, chiefly of American birth, with colored. It is intersected by the Northern Pacific railroad. It contains the Fort Seward military reservation. The surface in the vicinity of its co. seat is much diversified, in other portions stretching into level fertile prairies for miles on either side of the railroad track. Co. seat, Jamestown.

STUTTERING. This loose and imperfect action of the organs of articulation is often inaccurately confounded with *stammering* though physiologically distinct from it. The distinction will be found explained and elaborated in the article **STAMMERING AND DEFECTIVE SPEECH** (q.v.).

STUTTGART, the royal residence and metropolis of Württemberg, is beautifully situated in a widening of the Nesenbach valley, the hills forming a semicircle of eminences clothed with vineyards, orchards, and gardens. The basin in which Stuttgart nestles is 897 ft. above the sea-level, and enjoys a mild and healthy climate.

In the Altstadt, which occupies the center of the town, the streets are narrow and gloomy, but the new quarters, mostly erected during the present century, have fine, broad streets, symmetrical squares, and handsome buildings. The schloss, or palace, is a fine modern building. The royal park and gardens extend from the n.e. side of the palace for 2 m. in the direction of Canstatt, have an area of 560 acres, are adorned by fine groups of trees, and intersected by shady avenues, in which all classes may freely walk. The cathedral, built in the 15th c., was gifted by the king, in 1852, with several beautiful painted windows. Other principal buildings are the royal theater, public library, mint, museum of art, polytechnic school erected in 1860-65, the royal stables for 300 horses, etc. A fine statue of Schiller has been erected in the palace place. The extensive royal library is especially rich in MSS., Bibles in various languages, and specimens of early printing.

Stuttgart has many benevolent institutions and societies. There is direct railway communication with the leading cities of Germany, Switzerland, France, Belgium, and the Netherlands. Pop. '95 (including garrison), 158,321. Since 1866, and especially since the Franco-Prussian war, trade has increased in a remarkable degree. The principal industries are the manufacture of machinery, musical instruments, cotton and wool fabrics, carpets, leather, paper, glass, porcelain, gold and silver articles, jewelry, perfumery, chemicals, tobacco, beer-brewing, etc. Stuttgart has a high position in the book-trade, and is the place of meeting of the booksellers' union of southern Germany. Stuttgart was the birth-place of Hegel; here, also, Schiller's youth was spent. The

name of the city occurs for the first time in 1229. It was besieged by King Rudolph of Hapsburg, 1286-87, and appears then to have been a place of strength. Between 1634-38, nearly 9,000 people died of the plague; and during the wars of Louis XIV., Stuttgart was thrice taken; and again in 1796, 1800, and 1801.

STUYVESANT, PETER, 1602-82, b Holland; in early manhood entered the military service of the Dutch in the West Indies, and in 1634 was made director of the colony of Curaçao. In 1646 the Dutch West India company appointed him director-general of their American colonies. He soon gained the confidence of the colonists, and reconciled the Indian tribes who had been made hostile by former unjust treatment. He also succeeded in arranging with the English commissioners, in 1650, the boundaries between their respective territories. A convention of delegated colonists in 1653 demanded for the people, among other things, a confirming voice in the appointment of local officers. Stuyvesant, with characteristic boldness, ordered them to disperse forthwith, claiming that his authority was not from the people, but from God and the Dutch West India company. The people submitted, but with mingled feelings of chagrin and discontent. The protracted contentions of the Dutch and the Swedes, dwelling near the Delaware river, about governmental jurisdiction, became more critical in 1654 when the Swedish governor seized the fort built by the Dutch, where Newcastle now stands. To end this trouble, Stuyvesant with 600 men sailed up the Delaware, re-captured the fort, and established the Dutch authority over the entire territory. After ten years of undisturbed quiet, in 1664 an English vessel arrived with an armed force under col. Nicholls, who demanded a surrender of the government, on the ground that the whole territory was given by royal charter to the duke of York. Stuyvesant at first refused, but finding the people anxious to exchange rulers, he yielded to the English demand. Thus abruptly terminated the Dutch control over the New Netherlands, and both the town and the territory was thenceforth called New York. Stuyvesant reported personally to the authorities in Holland, but soon returned to New York for the remainder of his life. He cultivated an extensive farm called the Bouwerij, giving its name to one of the busy streets of the city. A pear tree in his garden, which he brought from Holland, bore fruit more than 200 years. As an interesting relic of the past and of the man so highly and so justly honored, the city authorities for many years protected this pear tree by a tall iron railing. Stuyvesant died in 1682, aged 80 years. He was buried where St. Mark's Church now stands, and the elaborately inscribed stone that covered his grave is built into the eastern wall of the church.

STYE, or **STR**, is the popular name for a minute boil occurring at the edge of the eyelid, and known to surgeons under the term *hordeolum*. It begins as a small, red, tense swelling, accompanied with considerable itching, and a feeling of stiffness. As the inflammation goes on, the lid may become so swollen as to keep the eye closed. In a few days, matter forms, a white point appears at the apex of the swelling; and when the cuticle gives way, pus and a small slough of connective tissue escape, after which there is a general remission of the symptoms, and the eyelid soon resumes its natural state.

This common affection is chiefly confined to scrofulous and delicate children, but it is sometimes observed in persons of more advanced age. The best local treatment consists in the application of warm-water dressings with lint and oiled silk; and if any hardness remains after the discharge of the matter, dilute nitrate of mercury ointment may be applied. The sty should never be rubbed (notwithstanding the common prejudice in favor of rubbing it with a gold ring), nor, in general, is it necessary to puncture it. To prevent the recurrence of these little boils, attention should be paid to the diet, which should be abundant and nourishing, to the state of the bowels, and to the general health; and tonics may usually be prescribed with advantage. The old form of the word was *stian*. See Holland's *Plinie*, book xxviii. ch. xi.

STYLE, OLD AND NEW. See **CALENDAR**.

STYLITÉS. See **PILLAR SAINTS**.

STYLOBATE, the substructure of a temple beneath the columns. It is sometimes continuous all round the peristyle in the form of three high steps; sometimes it resembles a continuous pedestal along each side, with flights of steps at either end.

STYPTICS (Gr. *styptikos*, astringent) are agents employed in surgery for the purpose of checking the flow of blood by application to the bleeding orifice or surface. See **BLEEDING**.

STYRAX. See **STORAX**.

STYRIA (Ger. *Steiermark*), a duchy forming one of the German crown-lands of Austria, is bounded on the n. by upper and lower Austria, e. by Hungary and Croatia, s. and w. by Carniola, Carinthia, and Salzburg. Its area is 8,671 English sq.m., and pop. '90, 1,282,708, who are partly of German and partly of Slavic origin. Styria is a mountainous country, being traversed in the w. and center by branches of the Noric Alps, which spread out into numerous ramifications; while the southern portion between the Drave

and the Save is occupied by branches of the Carnic Alps. The climate of Styria, like that of most mountainous countries, is variable, but is generally raw and cold in the northern and more mountainous portion, and mild in the south. But in spite of its physical character, agriculture is so zealously prosecuted that $\frac{2}{3}$ of the country are under cultivation, producing rye, wheat, oats, and maize. Vines are largely cultivated in various parts, and orchards are numerous. The chief wealth of the country, however, lies in its mineral products, which include, besides immense quantities of iron, lead, copper, zinc, graphite, marble, limestone, and slate, with abundance of salt and coal. The chief industries are thus necessarily in connection with the production of iron and steel, and their manufacture into articles of such excellent quality as to be in great demand in other countries. There are also manufactures of brass and lead articles, earthenware, paper, tobacco, glass, and of cotton, linen, cloth, chemicals, etc. Styria was anciently divided between Noricum and Pannonia, and has generally followed the fortunes of the two provinces of Upper and Lower Austria.

STYX (Gr. *stug-*, to hate, abhor), a water-fall in Greece, near the town of Nonacris, in the n.e. of Arcadia, descends perpendicularly over lofty and precipitous rocks, and forms a small torrent, which falls into the Crathis. The scenery around it is weird and desolate, so that the Greeks regarded the Styx with superstitious awe; the water being supposed to be poisonous, and to break every vessel into which it was put, except those made of the hoof of a horse or an ass. It was reported that Alexander the great had been poisoned by it. It is now called *ta Mauraneria* (the black waters), and also *ta Drakoneria* (the terrible waters), the belief in its poisonous qualities still surviving.—In mythology the Styx was a river of Hades, round which it flowed seven times, and over which Charon (q.v.) conveyed the shades of the departed. As a goddess Styx was the daughter of Oceanus and Tethys, dwelling in a grotto at the entrance of Hades. She was the confirmer of the most solemn oaths of the gods.

SUABIA. See SWABIA.

SUAKIN, a seaport belonging to Turkey, on a small rocky island in the Red Sea, off the w. coast of Africa, but near the shore, in lat. 19° 7' north. It has a good harbor, and a considerable trade in gum, ivory, ostrich-feathers, coffee, etc., and it is a station for pilgrims passing to and from Mecca. Population estimated ('82) at 11,000.

SUARez, FRANCISCO, the most celebrated of the modern scholastic and polemical divines of the Roman Catholic church, was born at Granada in 1548. His early studies were singularly unpromising; and it is remarkable, in the history of a man afterward so eminent, that it was not without great difficulty, and after repeated trials, that he obtained admission into the society of the Jesuits. His later career, however, was brilliant, quite in proportion to the dullness of his first beginnings; and he taught philosophy and theology with remarkable success, first at Alcalá, and afterward at Salamanca, Rome, and Coimbra. The accounts given of his habits of application to study are almost beyond belief. He is said to have habitually devoted seventeen hours a day to study. Of his power of memory, the marvels related are scarcely less prodigious. He is said to have been able to repeat at will any portion of the whole 23 folio volumes of his own works, even to the quotations from the fathers and other theological writers with which they abound. Suarez may truly be described as the ablest and greatest of the modern scholastics; but in his works scholasticism appears in its best form; for although they abound in discussions uninteresting, and indeed unintelligible, to persons unacquainted with scholastic terminology, yet they may also be truly said on each subject to exhaust the whole of the learning, ancient and modern, which existed relating to that subject at the date of their publication. On the philosophy of the ancients, Suarez is especially copious and accurate; and of most of the modern German philosophy we may find the germ in the pages which he devotes to the account of the opinions of the ancients.

In the scholastic controversies on grace and free will, Suarez was strongly opposed to the Thomistic doctrine; but he also rejected the opposite system of Molina. See **MOLINISM**. The scheme of reconciling the freedom of the will with the efficacy of grace, and of saving at the same time, the doctrine of "special election," devised by Suarez, is called *congruism*, and is explained under the head **MOLINA**. The works of Suarez are entirely theological, or ascetic, and were printed in 23 volumes folio at Lyons, Mainz, and Venice. An edition in 28 volumes 4to was completed at Paris in 1861. His treatise *De Legibus* is much esteemed, and has been reprinted in England. Suarez died at Lisbon in 1617.—See Des Champs, *Vie de Suarez* (4to, Perpignan, 1671).

SÜBAHDAR was, under the mogul government, the title of a governor of a province. It now designates a native officer, holding a rank equivalent to that of captain under the European officers.

SUBALTERN, in the army, or rather in a regiment, is a company officer below the rank of captain; i.e., a lieutenant.

SUBDEACON is an assistant deacon,—an order in the Roman Catholic Church next inferior to the order of deacons. This office had its origin in the early Christian Church, developing from the last named of the following two orders of that Church: the presbyteriate and the diaconate. The order rendered important aid to the diaconate in the

distribution of the charities of the Church ; its members were also sent on distant and important missions. It was however regarded by the Church as an office of human invention and its introduction was gradual and with little uniformity. After the division in the Church, subdeacons were retained by the Greeks as guards at the gates of the sanctuary during mass ; they also prepared the sacred vessels at the Prothesis, but were not allowed to touch the pater and chalice when they contained the Holy Eucharist. With both Greeks and Orientals, the order is still one of the minor or inferior orders. Among the Latins they were allowed to prepare the sacred vessels, also the bread and wine, for the mass, and poured the water into the chalice at the Offertory, and sang the epistle. Under Pope Gregory the Great (q.v.) the office was somewhat enhanced by its inclusion under the operation of the law of celibacy, and about 1200, under Pope Innocent III. (q.v.), it was counted among the major, or holy orders. The office is not retained in the English Church.

SUBDOMINANT, in music, the fifth below the tonic; the note whose dominant is the tonic. Thus F is the subdominant of C, and C of G. One of the keys most nearly related to any key is its subdominant; and the easiest of all modulations is that from a key to its subdominant, which is effected by adding the dominant seventh to the common chord, and the resolution of this chord is the common chord of the subdominant e.g., in modulating from the key of C to the key of its subdominant F, we have

See DOMINANT.

SUBIA'CO (anc. *Sublaqueum*), a city of the province of Rome, on a hill by the Teverone, 30 m. from Rome. Subiaco possesses a fine cathedral, and many monuments of antiquity. There was a famous Benedictine monastery in Subiaco, and here, in the 15th c., one of the earliest printing-presses in Italy was established. Pop. '81, 6503.

SUBJECT. See OBJECT.

SUB-KINGDOMS, ANIMAL, a term applied to the great primary divisions of the animal world. The sub-kingdoms are also named "morphological types," and this latter term serves to indicate their constitution more definitely than the name "sub-kingdom." As an example of the manner in which a "sub-kingdom" of animals is constituted, we may select that of the *Annulosa* or *Articulata*, a group of animals which was clearly defined by Cuvier himself, and which has remained since his day, with few alterations, as one of the most distinctive groups of the animal creation. A lobster may be selected as a typical example of this group. In the detailed examination of this animal, we may note that the jointed nature of the tail is perceptible in the fore part of the body, notwithstanding that the latter region consists apparently of a single piece. A further examination of the lobster's body would reveal the fact that each joint and its appendages—the latter being "paired"—agrees in essential or fundamental structure with every other joint of the body. The investigation of the plan of structure of the lobster's frame would show a very typical arrangement of parts. The heart lies dorsally, or on the back. The digestive system occupies a median position; and the nervous system lies ventrally, or on the floor of the body. The nerve-axis of the lobster further consists, typically, of a double chain of nervous masses (or *ganglia*) united by nervous cords, and from which branches proceed to the various parts of the body. The ideas we may gain regarding the general type of structure of the lobster's body, or plan on which that body is built up, may be thus summarized: (1.) The body is jointed; (2) the joints and their appendages are fundamentally similar or homologous; (3) the heart lies dorsally, the nervous system ventrally, while the digestive system occupies the median position; (4) the appendages are in pairs. Now, if we examine the body of any insect, we shall find it to essentially resemble that of the lobster in the general arrangement of its parts. The body of a spider or a scorpion exhibits a similar disposition of organs to that of the lobster, and shows a fundamentally similar structure beneath variations in appearance and form; and a centipede's body would be found to be also constructed on the lobster-type. The barnacles, water-fleas, crabs, and a whole host of animals more or less nearly allied to the lobster, and belonging to the lobster's class (that of the *Crustacea*), exhibit a near relationship with the typical animal; while worms generally (leeches, earth worms, etc.,) would present a fundamental similarity in their characters to those described as existing in the lobster. We thus discover uniformity of type beneath variations in form and appearance, and it is exactly this uniformity or broad structural likeness between apparently different animals which enables us to group them together to form "sub-kingdoms" or "types." A sub-kingdom or type of animals may therefore be defined as consisting of a number of animals whose bodies are constructed on the same fundamental plan. Lobsters, crabs, barnacles, etc., insects, spiders, scorpions, centipedes, and worms thus form the "sub-kingdom" *Annulosa*, on account of their agreement in fundamental structure, and in the essential characters just described as being typically exhibited by the lobster. The animal world is thus divided into five or six sub-kingdoms. Between some of these groups recent research—altogether unfavorable to the construction of defined sub-kingdoms or types—has demonstrated connecting links to exist. But by the great majority of zoologists, the following divisions are recognized:

- I. PROTOZOA—Ex.: Sponges, infusoria, amœbæ, and other animalcular forms.
 II. CŒLENTERATA—Ex.: Sea-anemones, corals, zoophytes, jelly-fishes, etc.
 III. ECHINOZOA—Ex.: Sea-urchins, star fishes, crinoids, sea-cucumbers, tape-worms, flukes, etc.
 IV. ANNULOSA—Ex.: Worms, insects, centipedes, spiders, crustacea.
 V. MOLLUSCA—Ex.: Sea-mats, sea-squirts, lamp-shells, shell-fish, cuttle-fishes.
 VI. VERTEBRATA—Ex.: Fishes, amphibia, reptiles, birds, mammals.

SUBLAPSA'RIAN (Lat. *sub-lapsum*, after the fall), the name given to one section of the school of divines, who maintain the doctrine of absolute decrees of election and reprobation. It is possible to conceive God making such a decree in two different ways, either on the hypothesis of his foresight of the fall of Adam, and thus of original sin, or independently of such foresight on his part, and without any reference to such foresight, and entirely out of his own free will and determination. The sublapsarian system supposes the former; and thus refers the eternal election or reprobation of men by God to his foreseeing that all men would fall in Adam, and thus would deserve eternal reprobation. Out of the entire mass of mankind thus fallen, he freely pre-elects some to life, and equally freely predooms others to death. This distinction is not confined to the Calvinistic schools; it is also found among the Roman Catholics. See SUPRALAPSARIAN.

SUBLIMATION is a chemical process similar to distillation, but differing from it in the nature of the substances to which it is applied. While in distillation *liquids* are converted by the agency of heat into vapor, which is condensed in the liquid form usually by the cooling action of water; in sublimation, *solid* bodies are reduced by heat to the state of vapor, which reassumes the solid form on cooling. Sublimation is usually conducted in a single vessel of glass or iron, the product being deposited in the upper part of it in a solid state, while the impure residue remains at the bottom; but in the case of sulphur, the vapor is condensed on the walls of a large chamber. Iodine affords a good example of sublimation. On gently heating the lower part of a Florence flask containing a little of this substance, a purple vapor rises, which almost immediately condenses in small brilliant dark purple crystals in the upper parts of the flask, while any impurity that may be present remains at the bottom. Among the substances obtained by this process, and employed in the pharmacopœia, are arsenious acid, benzoic acid, corrosive sublimate, and sublimed sulphur.

SUBLIME. Objects indicating great power, vast expanse, or lofty elevation, excite in the beholder a feeling of pleasurable elation; and the name "sublime" is applied both to the objects and to the feeling.

The precise quality in things that arouse this mode of pleasurable excitement has been variously assigned. According to Burke, *terror* is, in all cases whatsoever, either more openly or more latently the ruling principle, or, at all events, one of the chief sources of sublimity: Blair suggested that *mighty power or force* is the cause; Payne Knight ascribed it to *mental energy*; Kaimes considers it due to *height or elevation*; Dugald Stewart, in an elaborate essay, affirms that *elevation* is the leading characteristic, and that expanse and power are sublime by suggesting or implying great height; sir W. Hamilton says that sublimity requires *magnitude* as its condition, and exists in three forms—space, time, and power.

The feeling itself has also been described variously. If this could be fixed, we should have a key to the objective quality. Longinus characterized it, in reference to literary composition, as "filling the reader with a glorying and a sense of inward greatness." Some would call it a "sense of security" in circumstances of terror or danger. Hamilton describes it as "a mingled feeling of pleasure and pain—pleasure in the consciousness of the strong energy, pain in the consciousness that this energy is vain." The connection with the sentiment of power is generally admitted; but as the comparison of the object with self suggests our own littleness at the same time, there may be a doubt as to whether the emotion is due to the power, to the littleness, or to the combination.

Referring to the generic sentiment of power, which is evidently at the foundation, we find that the feeling of superior might in ourselves is cheering, elating, stimulating; and that the sense of littleness or inferiority is a depressing and enfeebling state of mind, a state of pure pain, redeemable in certain circumstances by other feelings, as when our inferiority is only in the comparison with an object of love or veneration, or when it is the condition of some compensating superiority—"the courtier stoops to rise." The presumption, therefore, is that the elation of the sublime is connected with the notion of power. It may be felt although the power is not actually possessed, but imagined, borrowed, or conceived, through a sort of sympathy with the *appearances* of great power or might. If this account of the feeling be correct, power must be a principal quality in its objects; and if with this we combine voluminous sensation (and the corresponding ideas, vastness of expanse and greatness of time), we shall probably be able to explain the sublime in all its forms.

SUBLIME PORTE is the official name for the Turkish Government. The name comes originally from the chief gate of the seraglio, which is called the *Babi Humayun*, or Sublime Gate, and is the place where justice is publicly administered.

SUBMARINE NAVIGATION. When the diving-bell (q.v.) had shown that air for respiration can be supplied to persons placed in adequately arranged vessels under

water, ingenious men began to speculate on the possibility of navigating closed ships or boats in similarly exceptional circumstances. Cornelius Drebell made a vessel to be rowed under water in the time of James I. In 1774 an inventor named Day lost his life during an experimental descent in Plymouth sound, in a vessel of about 50 tons burden. Mr. Bushnell, of Connecticut, in 1775, and Robert Fulton, about 1796, contrived submarine vessels, intended to be used in warfare. The vessel patented in 1859 by Mr. Delaney, of Chicago, was egg-shaped in transverse section, and diminished nearly to a point at each end. Although this method of navigation has never been put into successful practice, there is very little doubt as to its practicability, at least for special purposes. Additional interest was given to this subject in 1897 by experiments made with small submarine vessels designed to attack war-ships, but no very definite results were obtained at first.

SUBMAXILLARY GANGLION, one of the four sympathetic ganglia lying in the cephalic region, sometimes called cranial ganglia; but the latter term is rather misleading, as none of the ganglia are within the cranial cavity. The submaxillary ganglion is situated above the deep portion of the submaxillary gland. See **SALIVARY GLANDS**, *ante*. It is connected by filaments with the lower border of the gustatory nerve (nerve of taste, supplying the tongue). It also receives motor filaments from the chorda tympani nerve, a branch of the facial. It is small, rounded, and of a reddish-gray color; its filaments of distribution, five or six in number, arise from the lower part of the ganglion, and supply the mucous membrane of the mouth and Wharton's duct, some being lost in the submaxillary gland.

SUBORDINARY, or **SUBORDINATE ORDINARY**, in heraldry, a name given to a certain class of charges mostly formed of straight or curved lines. Heraldry vary a little in their enumeration, but the following are generally held to come within this category: the bordure (q.v.); canton (q.v.); flanche (q.v.); fret (q.v.); fusil; gyron; inescutcheon (q.v.); lozenge (q.v.); mascle (q.v.); orle (q.v.); pall (q.v.); pile (q.v.); quarter (q.v.); tressure (q.v.). See also **HERALDRY**.

SUBORNATION or **PERJURY** is the offense of procuring another to take such a false oath as constitutes perjury (q.v.) in that other. It is a misdemeanor, punishable anciently by death; afterward banishment, or cutting out of the tongue; then forfeiture of goods; and latterly, as at present, by fine and imprisonment.

SUBPCENA, in American law practice, means the writ or process by which the attendance of a witness in a court of justice is compelled. It is a writ issued by a court commanding him to lay aside his business and all excuses, and attend at the time and place indicated, under penalty of a fine. If the witness is required to produce a document, the writ is called a *subpoena duces tecum*. If the witness do not attend, and has not a good legal excuse, such as dangerous illness, he may be sued in an action of damages or committed to prison.

SUBROGATION, in law, the substitution of another person in the place of the original creditor. The person thus taking the creditor's place succeeds to all the rights of the latter. Subrogation is taken from the Roman law, and belongs to equity rather than to common law jurisprudence. It may be conventional, where it takes place from the agreement of the parties; or may result from the action of the law, as where it takes place for the benefit of co-promisors and for the benefit of sureties against their principals. When a second mortgagee pays the first mortgagee's claim, he at once becomes the equitable assignee of the first and can compel actual assignment, and so in all cases where a prior creditor is paid by a subsequent one. If an entire debt be paid by one of several joint debtors, he is entitled to contribution from the others and subrogation takes place.

SUB ROSA, "under the rose"—i.e., between ourselves, or in secrecy. It was customary among the ancient Germans, on occasions of festivity, to suspend a rose from the ceiling above the table, as a symbol that whatever was said during the feast by those present would be afterward forgotten, or at least be kept as a secret among themselves.

SUBSCRIPTION, in law, a written contract by which a person agrees to contribute a sum of money for a specified purpose; as a subscription for a college or a newspaper. If the contract be legal and grounded on good consideration a subscriber may be sued for his subscription as soon as the condition upon which he made the promise is fulfilled. It has even been held that subscribers for a common purpose may be regarded as contractors with each other, and the consideration of each subscription the promises of all the other subscribers, so that each subscriber may be sued by all the others. This seems to be scarcely tenable, and it is customary to make subscriptions payable to a treasurer. Wherever action has been taken upon the subscription by the expenditure of moneys or otherwise, before notice received of the withdrawal of a subscription, there is a consideration sufficient to support the promise, which may then be enforced.

SUBSIDIES, a term in politics, used in two different senses: 1. It is applied in English political history to taxes levied not immediately on property, but on persons, in respect of their reputed estates in lands or goods; or customs imposed on any of the staple commodities in addition to the *costuma magna et antiqua*. Thus 30,000 sacks of wool were granted to Edward III. in 1340, in aid of the war with France. Subsidies were granted on various occasions to James I. and Charles II. 2. The same word is

used to denote money paid by one state to another, in order to procure a limited succor of auxiliary troops, ships of war, or provisions. In the time of the war with the revolutionists of France and Napoleon I., Great Britain furnished subsidies to foreign powers to a large extent, in order to engage them to resist the progress of the French. In questions regarding subsidies, it is held that the state furnishing the succor does not thereby become the enemy of the opposite belligerent; it may remain neutral in all respects, except as regards the auxiliary forces supplied. Such, for example, was long the attitude maintained by the confederate cantons of Switzerland: while granting troops to the various European powers, they were in the habit, at the same time, of preserving a rigorous neutrality. The service of Swiss regiments abroad is no longer sanctioned. The federal constitution of Switzerland, of Sept. 12, 1848, prohibited the conclusion of military capitulations; and on July 30, 1859, a proclamation was issued by the federal council, forbidding any Swiss subjects from taking service under a foreign power, without the authorization of the council.

SUBSTANCE, a word connected with certain discussions in logic and metaphysics. Substance is correlative with quality or attribute. Every substance must have attributes, and every attribute must be the attribute of some substance. The substance gold has the attributes weight, color, etc. But as every power or property of a thing, every way that the thing affects us, may be called an attribute or quality, if all the attributes are counted off, there is nothing left; and the question then arises: What is the *substance*? To avoid this seeming inconsistency, it was assumed that everything whatsoever possesses, besides its attributes, an unknown substratum that they rest upon, or inhere in—a mystical and inscrutable bond, that holds the attributes together, without being itself an attribute. This gratuitous assumption of what is, after all, a nonentity, was repudiated by Locke and others, who found a meaning for substance without departing from the knowable. Every object has some *essential* or *fundamental* quality, which being present, it preserves its identity; and which being removed, it is no longer the same object, but another. Thus the substance of body or matter is not the remnant after all the qualities are subtracted; it is the two fundamental and inerasable qualities, extension and resistance; size, shape, color, heat, odor, etc., may all be varied; but so long as extension and resistance in any degree are found, we have a piece of matter. On the same view, the substance of mind is whatever we regard as its fundamental essence, or distinguishing marks. We may adopt feeling, or volition, or intellect, or require a share of all three, according to our mode of defining the mind. It would, then, be a mere confusion of language to talk of feeling, volition, and intellect as *inhering* in mind; they *are* mind, and there is nothing besides.

Notwithstanding the obviousness of this explanation, the employment of the words substance and attribute has led to such an inveterate demand for something that shall underlie all attributes—a substance of body, and a substance of mind—distinct from anything meant by the names, that many philosophers have considered it necessary to preserve the phantom as a thing of belief, if not of knowledge. The doctrine of an unknowable substance in the abstract very early allied itself with the popular theory of the perception of a material world (see PERCEPTION), and the same arguments are good, for or against both. Other names for expressing the same contrast are *noumenon* and *phenomenon*. The phenomenon is what shows itself to our senses, or is conceived by our intelligence—the qualities of extension and resistance in body; and of feeling, etc., in mind. The noumenon is something apart and beyond, something inconceivable and unknowable, but which, say some, we are instinctively led to believe in. Thus, in the great question above alluded to—the belief of an independent material world—the phenomenal manifestations are inextricably involved with our mental powers of conceiving, and would vary, if these were to vary; consequently, they cannot be the absolute, independent, self-existent reality; which drives one school of philosophy upon the expedient of believing in such a reality, although it must be for ever incomprehensible to us.

SUBSTITUTE, MILITARY. In nations where conscription is resorted to for the supply of soldiers for the army, the lot often falls on those unwilling to serve in person. In such a case the state sometimes agrees to accept the services of a substitute who is of equally good physique. Unless the levy be very extensive, or the term of military service very long, substitutes are readily found among military men who have already served their prescribed period. Of course, the substitute must be paid for the risk he runs. His price depends, like all other saleable articles, on the demand and supply. In the United States, when conscription was resorted to, during the civil war, many of those who were drafted sent substitutes in their place. The price of a substitute rose toward the end of the war to \$1000 or \$1500.

SUBSTITUTION is one of the three principal methods employed in examining the chemical composition of organic bodies, and in tracing their relation to other compounds; the two other methods being those of *oxidation* and of *reduction*. Although the term is restricted to organic chemistry, the ordinary method of preparing insoluble inorganic compounds by double decomposition is in reality a case of substitution of one base or one acid for another. If, for instance, solutions of nitrate of lime and sulphate

of soda are mixed together, the resulting compounds are sulphate of lime and nitrate of soda, in which the lime is substituted for the soda, and the soda for the lime. In some cases an element may be replaced (or, more correctly, displaced) by a compound group; thus, cyanogen, CN, may take the place of oxygen, as, for example, in the reaction that ensues between hydrocyanic acid and red oxide of mercury, when cyanide of mercury and water are formed, as shown in the equation $2\text{HCN} + \text{HgO} = \text{Hg}(\text{CN})_2 + \text{H}_2\text{O}$. Similarly, the groups NO_2 , HSO_3 , and NH_2 may often be substituted for hydrogen. In various organic bodies, one or more atoms of hydrogen may be displaced by one or more atoms of chlorine, a fact which was originally observed by Gay-Lussac in noticing the action of chlorine on wax. The new product thus formed is almost always analogous in its nature to the compound from which it is produced; thus, according as the substance acted on by the chlorine is an acid or a base, the resulting product is an acid or a base, and the number of atoms is always the same in the original substance and the product. The following examples will elucidate the above remarks: If acetic acid, $\text{CH}_3 \cdot \text{CO}_2\text{H}$, be exposed to the action of chlorine, we obtain, according to the duration and modifications of the action, the two compounds, monochloroacetic acid, $\text{CH}_2\text{Cl} \cdot \text{CO}_2\text{H}$, and trichloroacetic acid, $\text{CCl}_3 \cdot \text{CO}_2\text{H}$, in the former of which, one atom, and in the latter, three atoms of hydrogen, are displaced by a corresponding number of atoms of chlorine. Ethyl chloride, $\text{CH}_3 \cdot \text{CH}_2\text{Cl}$, may be made to yield the following succession of compounds, in which a gradually increasing amount of the hydrogen is displaced by chlorine, until, in the final result, the hydrogen has altogether disappeared. The consecutive compounds thus resulting from ethyl chloride, $\text{CH}_3 \cdot \text{CH}_2\text{Cl}$, are (1) ethylidene dichloride, $\text{CH}_3 \cdot \text{CHCl}_2$; (2) trichlorethane, $\text{CH}_3 \cdot \text{CCl}_3$; (3) tetrachlorethane, $\text{CH}_2\text{Cl} \cdot \text{CCl}_3$; (4) pentachlorethane, $\text{CHCl}_2 \cdot \text{CCl}_3$; and (5) hexachlorethane, $\text{CCl}_3 \cdot \text{CCl}_3$. "The chlorine," says prof. Miller, "appears to have taken the place of hydrogen in the group without disturbing the relative position of the other elements which enter into its formation; just as a brick in an edifice may be conceived to admit of being removed, while its place is supplied by a block of wood or of stone, without altering the form or symmetry of the building." Substitutions of bromine and iodine for hydrogen may be effected in the same way as has been shown to occur in the case of chlorine. The study of the artificial formation of organic bases has led to the discovery of many remarkable instances of substitution products. If, for example, ethyl bromide, $\text{C}_2\text{H}_5\text{Br}$, is heated in a sealed tube with a solution of ammonia in alcohol, ethylamine hydrobromide is formed, and on distilling this with hydrate of potash, one of the products is a new base, ethylamine, $\text{C}_2\text{H}_5\text{NH}_2$, which may be regarded as ammonia, NH_3 , in which one atom of hydrogen has been displaced by one molecule of ethyl, C_2H_5 . By a similar proceeding, we may successively displace the second and the third atoms of the hydrogen in the ammonia; and we thus obtain two more complex bases, diethylamine, $(\text{C}_2\text{H}_5)_2\text{NH}$, and triethylamine, $(\text{C}_2\text{H}_5)_3\text{N}$.

SUBTRACTION, one of the four fundamental processes of arithmetic, is the diminution of a quantity by the removal of a certain portion of it. It is consequently the reverse of *addition*, and determines how much of any quantity remains after a certain quantity has been taken from it. In cases where the digits of the number to be subtracted are greater than the corresponding ones of the number to be diminished, two methods of operation may be adopted.

| (1) | (2) | (3) |
|------|---------------|---------------|
| 7324 | 7 (13) (12) 4 | 6 (13) (12) 4 |
| 1842 | (2) (9) 4 2 | 1 8 4 2 |
| 5482 | 5 4 8 2 | 5 4 8 2 |

For example, in subtracting 1842 from 7324, the numbers are written as in form (1). The method of operation usually followed is to make an addition mentally to the upper figure when necessary, and then compensate for this by an equivalent addition to the next under figure, as represented in form (2). Thus 10 "tens" are added to 2 "tens," to enable 4 "tens" to be subtracted; and this addition is compensated for by an equal increase of the under line by 1 "hundred," through the change of 8 "hundreds" into 9 "hundreds." The more simple and directly intelligible plan, shown in form (3), is to borrow a unit of the next higher degree in the upper line, care being taken to remember in the partial subtraction immediately succeeding, that the upper digit must be considered as less by unity than it appears.

SUB-TREASURY WAREHOUSE SCHEME. A plan favored by some members of the Farmers' Alliance (q.v.) in 1890-91, and embodied in a bill introduced into Congress by Mr. Vance, of South Carolina. The bill proposed that the Treasury Department establish in each county of the several states a branch to be styled a sub-treasury, on the petition of 100 or more citizens of the county. These sub-treasuries were to receive on deposit cotton, wheat, corn, oats, or tobacco from citizens, in return for which treasury notes up to the value of 80 per cent. of the value of the deposit would be issued to the depositor in the nature of a loan at the annual rate of one per cent. interest. On the repayment of the loan, the deposit of grain, etc., was to be returned.

SUBWAYS. The system of engineering *beneath* the public streets has not by any

means yet reached its full development. Subways for foot passengers are occasionally constructed in connection with railway termini; one such connects the Bishopsgate (London) station of the Metropolitan railway with the Liverpool street station of the Great Eastern; another connects two Victoria stations at Pimlico, belonging to different lines and companies. The *Tower Subway* is a remarkable instance of a passage under the Thames for foot-passengers. The Metropolitan or underground railway, opened in 1863, was the first example of its kind; the passengers going down-stairs from the side pavements to stations underneath the carriage-way. The pneumatic propulsion of mail-bags (see PNEUMATIC DISPATCH) has given rise to projects for a similar mode of propelling railway trains beneath streets and roads. One such, the Waterloo and Whitehall railway, was commenced about 1865, to pass under the Thames; want of funds led to its abandonment after shafts had been sunk. The term *subways* is usually applied, not to such tunneled passages for traveling, but to roomy archways that will contain sewer-pipes, water-pipes, and gas-pipes. It has been long considered a defective system that whenever such pipes need repair, the surface of the street has to be broken up to get at them, thereby causing great expense and great interruption to traffic. When the metropolitan board of works commenced their series of improvements, they resolved on the trial of subways for this useful purpose. They began with a new street, extending from Covent Garden market to St. Martin's lane, opened in 1861. Underneath the carriage-way of this street, there is a subway, a central arched passage or tunnel 12 ft. wide by 6½ ft. high; with arched side-openings for house service-pipes connected with the cellarage of the several dwellings. In this subway are water-pipes, gas-pipes, and electro-telegraphic wires, all easy of access by side entrances to the subway, of sufficient size to admit workmen, pipes, etc. In this instance, the main sewer is not in the subway itself, but underneath it, provided with man-holes, gullies, ventilating shafts, etc. A second example is afforded by Southwark street, lately formed from Blackfriars road to the southern foot of London bridge. Underneath this street extends a subway, excellently planned for the purposes above mentioned. Two street lamp-posts, of unusually elegant design, one at each end of the street, act as ventilating shafts for the subway, and there are other ventilators along the route, besides side entrances for workmen. A curious proof has been furnished, however, of the anomalies which so frequently mar our public works. In 1865, a gas company broke up the roadway, and broke through the well-built crown of the arch of the subway, to get at their gas-pipes for purposes of repair or adjustment. It was found, on investigation, that no one had power to prevent them. The act empowered the metropolitan board of works to make a subway for the use of gas companies, water companies etc.; the gas company, on the other hand, were empowered by *their* act to break up the public roadways to get at their pipes; the board could not compel the company to adopt the new plan, because the powers were only permissive, not obligatory. The water companies and gas companies fear incurring additional expense; and there is known to be a difference of opinion among engineers concerning the danger from leakage and explosion when the two sets of pipes are inclosed in the same archway.

The subway system, after overcoming these and other difficulties, has made a great advance within a recent period. Queen Victoria street, and several other new streets, have been provided with subways similar to that under Southwark street. The Victoria or northern Thames embankment presents some fine examples of subway engineering. Between the masonry of the river-wall and the former line of high water, there are no less than three tunnels or arched passages under the surface of the ground parallel to the course of the river. One is the metropolitan district railway; another is the low-level sewer of the Great Main Drainage system; while a third is a subway to contain gas and water-pipes, telegraph wires, etc. The most extraordinary plan, perhaps, ever seriously proposed in subway engineering is connected with the spot where Tottenham Court road, Euston road, and Hampstead road join. The Metropolitan railway is here flanked on either side by sewers; above it, but below the level of the street, are several gas and water pipes, drains, and ventilating shafts; while crossing immediately over the Metropolitan railway, at right angles, is the tube of the (still abortive, 1879) pneumatic dispatch (q.v.). Beneath all this is the section of another tunnel, intended to join the Midland and North-western railways with the South-eastern. Civil engineers and contractors are ready to grapple with the difficulties of this extraordinary work whenever financial circumstances are favorable. See RAILWAYS; TUNNEL. A system that appears to have been very successful in London, and which in consequence is advocated by many for introduction into New York as a means of solving the rapid transit problem, is that known from its promoter as the GREATHEAD SYSTEM. Mr. Greathead secured for his plan a parliamentary concession in 1888, and constructed a subway from the Monument to South Lambeth, a distance of more than three miles, at a depth below the streets of from 40 to 60 feet. It is composed of two tunnels which are circular and driven through sand, clay, or rock, by instruments prepared for the purpose; and which are composed, after the opening has been made, of sections of iron rings bolted together and with the interstices filled with tarred rope, and surrounded by a coating of Roman cement impervious to water. Hydraulic elevators carry passengers up and down shafts sunk from the street-level. The advantages of the Greathead system are

(1) the great depth which allows the tunnel to be constructed with little interference to buildings on the surface, and which consequently lessens expense; (2) the use of electricity as the mode of tractions, thus avoiding the noise, smell, and dampness inevitable when steam locomotives are used; (3) the higher rate of speed possible, it being on an average from 22 to 26 miles an hour. The original Greathead line was opened Nov. 4th, 1890; since which time, four similar projects have been started. See an article by Mr. Simon Sterne in the *Forum* for August, 1891.

SUCCESSION is a legal term used in Scotland, but not used technically in England, where the same subject is spoken of under the name of next of kin (q.v.) and descent; see also ADMINISTRATION AND ADMINISTRATOR; DISTRIBUTION, STATUTE OF; EXECUTORS; INTESTACY.

SUCCESSION ACTS. From a comparatively early period in English history, parliament occasionally exercised the power of limiting or modifying the hereditary succession to the throne. The first instance of such interference occurred in the reign of Henry IV., who possessed himself of the crown, to the prejudice of the descendants of Lionel, duke of Clarence, second son of Edward III. Act 7 Henry IV. c. 2 confirmed the title of that monarch, and declared prince Henry heir-apparent of England and France, with remainders to Henry IV.'s other children. Parliamentary interposition was subsequently exercised in the case of Henry VII. and in regard to the immediate successors of Henry VIII. The respective rights of James I., Charles I., and Charles II. were acknowledged by parliament; and in the case of Charles II. the crown was held to have devolved on him immediately on the death of his father.

The revolution of 1688 was founded on the so-called abdication of the government by James II. See ABDICATION. The convention bestowed the crown on William and Mary for life, and regulated the claims of Anne. On the impending extinction of the Protestant descendants of Charles I., the crown was settled by 12 and 13 Will. III. c. 2, in the event of the death of William and Anne without issue, on the next Protestant line, according to the regular order of succession—viz., the descendants of the electress Sophia of Hanover, granddaughter of James I.; and it was at the same time enacted, that whoever should hereafter come to possession of the crown, should join the communion of the church of England as by law established. This is the latest parliamentary limitation of the crown; but the right of parliament to limit the succession has been secured by 6 Anne, c. 7, which attaches the penalties of treason to the "maliciously, advisedly, and directly" maintaining, by writing or printing, that the king and parliament cannot make laws to bind the succession to the crown, and the penalties of a *præmunire* (q.v.) to maintaining the same doctrine by preaching, teaching, or advised speaking.

SUCCESSION WARS were of frequent occurrence in Europe, between the middle of the 17th and the middle of the 18th centuries, on the occasion of the failure of a sovereign house. The most important of these wars was that of the Orleans succession to the Palatinate (1686-97), closed by the peace of Ryswick; of the Spanish succession (1700-13); of the Polish succession (1733-38), closed by the peace of Vienna; of the Austrian succession (1740-48); and of the Bavarian succession (1777-79), called, in ridicule, the potato-war. Of these, the second and fourth were by far the most important, and a brief notice of their course and conclusion is subjoined.

SUCCESSION, WAR OF THE SPANISH, arose on the death, without issue or collateral male heirs, of Charles II., king of Spain, Nov. 3, 1700. The nearest natural heir to the throne was of the royal line of France, Charles's elder sister having married Louis XIV.; but to prevent any possible union of the two crowns, a solemn renunciation had been exacted both from Louis and his queen, for themselves and their heirs; and this renunciation having been ratified by the king and cortes of Spain, was made as binding as legal forms could make it. Failing the Bourbons, the next heirs were the descendants of the younger sister of Charles, who had married the emperor Leopold I., and from whom no renunciation had been exacted; and the only issue being a daughter, who had married the elector of Bavaria, and borne a son, Joseph Ferdinand, this prince was during his lifetime regarded both by Charles II. and the Spanish people as the rightful heir. But, dying in 1699 without issue, the question of succession was reopened, Louis XIV., failing his wife's rights, claiming for himself, as the son of Philip IV.'s elder sister (being, however, again legally barred here by another solemn renunciation); while the emperor Leopold, maintaining with justice that the Bourbons were by these two renunciations wholly deprived of all their rights of heirship, claimed the throne as the son of Philip IV.'s younger sister. The other powers of Europe, especially Britain, Holland, and Germany, warmly interested themselves in the matter, as a question of policy, and with good reason; for not only was the crown of Spain a valuable prize in itself, carrying with it the sovereignty of the Netherlands, the Milanese, Naples, and Sicily, and immense possessions in America, but its union with France or Austria would of a certainty endanger the independence of every other sovereignty in Europe. Both claimants bade for the support of the maritime powers, the one by renouncing his claims in favor of his second grandson, Philip of Anjou, the other by putting forward his second son, Charles, as his substitute, while both solemnly promised never to undertake the union of the two crowns. The Austrian party at first preponderated in Spain; but Louis, by able and unscrupulous policy, succeeded in undermining the Austrian influence at Madrid, and in having Philip declared the heir (Oct. 2, 1700). On the death of king Charles, a month

after, Philip appeared in Spain, and was well received by all classes, and at once recognized as monarch, an example gradually and unwillingly followed by all the European powers excepting the emperor; for at that time the dread of Louis XIV.'s power pressed like an incubus on the nations of Europe. However, the French monarch, by various ill-advised acts, chiefly by his support of the elder pretender (the son of James II.), whom he recognized as sovereign of Britain, and by occupation of the Netherlands and menacing treatment of Holland, stirred up such general resentment, that William III. was enabled to revive the *grand alliance*, and his successor, Anne, to join with Holland and Austria in declaring war against France and the "Spanish usurper," May 15, 1702.

Hostilities at once commenced; a combined British-Dutch-German army under Marlborough attacked the French in Belgium, and captured one by one their fortresses on the Maes, while the Reichs army (Germany having declared for Austria), under the Markgraf of Baden, crossed the Rhine, and took Landau. Austria herself had, however, commenced the contest in the previous year by sending into Italy prince Eugene (q.v.) of Savoy-Carignan at the head of a veteran army of 32,000 men, who did a good deal of hard fighting, with no adequate result. Meanwhile, the elector of Bavaria raised an army and declared for France, and a French army under Villars marched to join him. Both were kept in check by the Markgraf for some time; but, in the summer of 1703, Villars burst through the Black Forest, and joined the elector, with the view of penetrating through Bavaria into Austria, but his obstinate ally, the elector, was determined to invade the Tyrol instead, and join Vendome in northern Italy—a scheme which ended most disastrously; and Villars returned in disgust to France. In the Low Countries, Marlborough employed himself in gradually depriving the French of their strongholds: in Italy the Austrians were driven from point to point, till nothing remained to them but a few districts on the Po; they were, however, relieved toward the close of the year by the defection from France of the duke of Savoy, who joined the grand alliance Oct. 25, 1703, an event which compelled Vendome to return to Piedmont. The first great blow was struck in the following year, when the combined Austrian-German-British army, under Marlborough, totally defeated the French and the elector at Blenheim (q.v.), driving the débris of their forces almost to the foot of the Vosges. After this the French never obtained a permanent footing in Germany. The campaigns of Marlborough in Germany, and of Eugene in Italy, in 1705, were successful but not very important. The year 1706 was another great epoch in this protracted contest; the British and Dutch having freed the valley of the Maes, had forced the French into South Brabant, and Marlborough having, by a stratagem, caused them to march toward Namur, suddenly attacked them at Ramillies (q.v.), and, after a brief combat, put them completely to rout with great slaughter, the elector and Villeroy, the joint commanders, narrowly escaping capture. Louis hastily re-enforced his army, and recalled Vendome from Italy to take the command, a step which, however necessary, cleared the way for Eugene who completely out-generated his opponent Marsin, and after a memorable march of 34 days, appeared before Turin, and united with the duke of Savoy. The battle of Turin, in which the gallant Marsin was slain, was one of the most obstinate of the whole war, but its result was as decisive, and from this period the French power in northern Italy was shattered: and the following year saw the country completely cleared of both French and Spaniards. From 1706 the war in Germany was purely defensive, and no battle worthy of notice was fought. In Italy also the contest on the whole languished, though the Austrian arms were for the most part successful, Mantua and Naples (1708) being subdued, and the pope compelled to preserve neutrality by dread of another sack of Rome. But since the commencement of 1704, another theater of war had been established by the landing of the archduke Charles at Lisbon with 8,000 British and 6,000 Dutch troops, who were joined by the Portuguese (their king having acceded to the alliance against France), and invaded Spain from the west; but nothing of consequence was accomplished till a landing had been effected by the earl of Peterborough (q.v.), with a small body of troops, in Catalonia. Then attacked both from the w. and e., the Bourbon forces were beaten and driven across the Pyrenees, and it was only after the departure of Peterborough that Berwick (q.v.) made head against his antagonists. By his victory at Almanza (April 25, 1707), he recovered the whole of Spain except Catalonia. In 1710 Berwick finally left Spain; and the Carlists under Stanhope and Starhemberg again got the upper hand, repossessing themselves of the e. of Spain, and of Madrid (Sept. 28). But the arrival of Vendome speedily changed the face of affairs. Stanhope was defeated and captured (Dec. 9) at Brihuega, and Starhemberg was forced to retreat on the following day. The war was thenceforth confined to Catalonia, and was distinguished by no noteworthy incidents. The most important part of the struggle had been meanwhile taking place in the Netherlands, where Marlborough (1707) drew up in concert with Eugene a secret plan of operations which affected a division of the Moselle army under the elector and Berwick from that of the north under Vendome; whereupon the British and Germans swiftly uniting fell upon Vendome's army at Oudenarde (q.v.) (1708), and before Berwick could come up to its aid, inflicted upon it a severe defeat. The capture of Lille, Ghent, and Bruges necessarily followed. France now began to show symptoms of exhaustion, and made overtures of peace, but these being chiefly illusory, were rejected; and the emperor having largely re-enforced Eugene, the allies took the field with 110,000 men,

while the French, equal in strength, were now directed by Villars, the most enterprising and fortunate of their generals; but his star, which had hitherto been constantly in the ascendant, fell before that of Marlborough at Malplaquet (q.v.) (Sept., 1709). After some further campaigning, besieging, and negotiating, the opportune death of the emperor (April 17, 1711) rescued France from the brink of destruction; for Britain became immediately lukewarm in support of a cause which would effect the reunion of Austria and Spain; and the Tories having come into power, private preliminaries of peace were signed between Britain and France, Oct. 8, 1711. Eugene, however, continued the war, aided by Holland, and captured Quesnoy; but the defeat and capture of the earl of Albermarle and the British contingent at Denain (July, 1712) so weakened his force, that he was compelled to give way; and in the following spring the Dutch joined the British as parties to the peace of Utrecht (q.v.). The emperor Charles was also forced to conclude a treaty of peace at Baden, Sept. 7, 1714, which ended the struggle, leaving Philip in possession of the Spanish throne (see *UTRECHT*); while Austria obtained the Spanish Netherlands and the Milanese.

SUCCESSION, WAR OF THE AUSTRIAN. The death of the emperor Charles VI. (Oct. 20, 1740), by which the male line of the house of Hapsburg became extinct, was the signal for a general uprising of the powers of Europe, some to prey on the Austrian possessions, and others to aid the eldest daughter and heir of the deceased emperor. The probability of such a contingency had long been foreseen by Charles VI., for as early as 1713 he had published a *Pragmatic Sanction* (q.v.), stipulating that, in default of male heirs, the whole of his dominions should descend undivided to his eldest daughter, Maria Theresa (q.v.); and it was almost his sole aim, during his subsequent reign, to gain the consent of all parties having proximate claims to any of the Austrian domains, and of the principal powers of Europe, to this arrangement. The elector of Bavaria, Charles Albert, alone refused to resign his pretensions. On the death of her father, Maria Theresa intimated her accession to the various European powers, and from all of them, except France and Bavaria, received assurances of good-will and support; but notwithstanding, two months did not elapse till Frederick II. of Prussia, without a declaration of war, invaded Silesia. The Austrian treasury was at this time exhausted, and the army much disorganized; so that little or no effective resistance could be made to the Prussians; while the state of alarm into which this sudden attack had thrown the court of Vienna was increased by doubts as to the intentions of France. These doubts were soon resolved by the latter, in the spring of 1741, forming a confederacy of all the claimants to the Austrian dominions—the electors of Bavaria and Saxony, sons-in-law of the emperor Joseph I.; Philip V. of Spain; Charles Emmanuel of Sardinia, who claimed the Milanese; and Frederick II. of Prussia, who *now* demanded almost the whole of Silesia. On the other hand, Britain granted Maria Theresa an annual subsidy of £300,000; the Dutch were willing to aid her when opportunity offered; and Hungary gallantly responded to her pathetic appeal by sending in thousands her motley population, Magyars, Croats, Slavs, and Toltatches, to fight in defense of their heroic queen. Meantime the Bavarians, in conjunction with the French under Belleisle, overran the greater part of Bohemia. This invasion compelled the queen to buy off her most formidable opponent, Prussia, by the surrender of Silesia and Glatz; and then, while prince Charles of Lorraine kept the French at bay in Bohemia, Khevenhuller, the most enterprising of the Austrian generals, advanced up the valley of the Danube, captured 12,000 French in Linz, overran Bavaria, and on the very day of the elector's coronation as the emperor Charles VII., took Munich his capital (Feb. 12, 1742). But this great success alarmed Frederick II. for the security of his new possessions, and abruptly breaking the treaty, he poured his forces into Bohemia and upper Austria, and gained the battle of Chotusitz (May 17). The same year witnessed increased activity on the part of Britain (the Walpole administration being now in power) and Holland on behalf of Austria; the expulsion of the French and Bavarians from Bohemia; the severance of the king of Sardinia from the coalition against Austria, produced by the bribe of some districts of the Milanese, which, however, he did not obtain till some time afterward; the enforcement of neutrality upon Naples by the threatening attitude of a British fleet off the capital; and, on the other hand, the recovery of Bavaria by the elector.

In May, 1743, Bavaria again fell into the hands of prince Charles and Khevenhuller; count Saxe was driven with great loss from the Palatinate; the "emperor" Charles Albert and the Swedes, disgusted at their ill-success in the war, retired from the contest, so that France and Spain now remained the sole representatives of the once mighty coalition. In 1744, France and Britain, which had hitherto engaged in the conflict only as allies, declared war on each other; and the latter proceeded to destroy piecemeal the French and Spanish shipping on the high seas, and to attack their colonial possessions. For this, however, the successes of Saxe in the Netherlands were a compensation. However, the great successes of Austria on the Rhine, and the ill-concealed ambitious projects of Maria Theresa, again alarmed Frederick II. for Silesia; and he resolved on another attempt to rivet his hold on the much-coveted province before it was too late. Accordingly, he concluded at Frankfort (May 13, 1744), a secret convention with France, the emperor, the elector-palatine, and the king of Sweden. Bursting into Bohemia with his usual celerity, Frederick II. forced the Austrians at once to return from Alsace, thus enabling the elector to recapture Bavaria; but before prince Charles had time to reach

Bohemia, a fresh levy of 44,000 men, which had been raised by the chivalrous and patriotic Hungarians, joined by 6,000 Saxons, had reached the Prussians, and by cutting off their supplies, and capturing their stragglers and foraging parties, compelled them to evacuate the kingdom with considerable loss. In Italy, the Spaniards, who were now joined by the Neapolitans, were defeated repeatedly, and compelled to retreat down the peninsula; and the king of Sardinia succeeded in preventing the French from effecting a permanent lodgment in n.w. Italy. In January, 1745, the emperor-electoral died, and his son, Maximilian Joseph, profiting from his father's misfortunes, declined to take part in the contest, or to allow himself to be nominated emperor, and made peace with Austria. Frederick II., displeased with the meddling and overbearing conduct of France with respect to the approaching imperial election, also sought to come to terms with Austria, by the mediation of Britain, and the peace of Dresden (Dec. 25, 1745) finally withdrew Prussia from the conflict. In Flanders, the fortunes of Austria also declined; and after the victory of Fontenoy (May 11, 1745) she could not prevent Saxe from capturing the chief Belgian fortresses in succession. In Italy, also, fortune declared for the coalition; for the Spanish-Neapolitan army, now re-enforced by the Genoese and Modenese—70,000 men in all—defied all opposition, overran the whole of Lombardy and much of the Sardinian territories, driving the king under the walls of his capital. Similar reverses befell the allies in Flanders during the campaign of 1746; but these were more than counterbalanced by the great successes obtained in Italy, where all the lost fortresses of Lombardy, Parma, and Guastalla, were recaptured, the coalition army totally routed in a great battle near Placentia (June 16), and Genoa overrun and occupied. Another of fortune's favors to Austria was the death of Philip V. of Spain (July 9), which, by depriving that arch-plotter, his queen, of the supreme power, considerably diminished the zeal of the Spanish court in the prosecution of the war. In 1747, the Dutch, who had hitherto escaped the ravages of war, were made practically acquainted with them by Saxe, who, having completely subdued the Austrian Netherlands, invaded and overran Dutch Flanders, routed the unfortunate duke of Cumberland at Laffeldt (July 2), while his celebrated chief of engineers, count Lowendal, after a two months' siege, took Bergen-op-Zoom, Cohorn's masterpiece, a fortress believed by the Dutch to be impregnable. At the commencement of 1748, Britain, France, and Holland sought to bring about a peace, and agreed among themselves to certain preliminaries, which were submitted to Austria and Sardinia; but as one of them was the surrender of Parma and Placentia to Don Philip of Spain, the former refused her consent; and her two allies, disgusted at her disregard of the sacrifices they had made on her behalf, at once signed the preliminaries (April 30), and Austria sullenly followed suit on May 18. Much discussion followed, but on Oct. 18, 1748, the treaty of Aix-la-Chapelle (q.v.) put an end to this most disastrous war, which left the Hapsburgs in possession of their hereditary dominions, with the exception of Silesia and some of their Italian provinces. See AIX-LA-CHAPELLE.

SUCCINIC ACID, $C_2H_4(CO_2H)_2$, derives its name from its having been originally found in amber (Lat. *succinum*), and is one of the group of dibasic acids of the oxalic acid series, whose general formula is $C_nH_{2n-2}O_4$. Succinic acid occurs as a natural constituent not only in amber, but also in the resins of many of the pine tribe, in the leaves of the lettuce and wormwood; and, in the animal kingdom, it has been detected in the fluids of hydatid cysts and hydrocele, in the parenchymatous juices of the thymus gland of the calf, and of the pancreas and thyroid gland of the ox.

One of the most important points in connection with succinic acid is its convertibility into tartaric acid, while tartaric acid may in its turn be reconverted into succinic acid.

SUCCOTASH (Indian, *msickquatash*) is an article of food common in the United States, and is made of corn and beans boiled together. The dish, as well as the name, originated with the Narragansett Indians.

SUCCORY. See CHICORY.

SUCCOTH, or SUKKOTH, one of the Egyptian "treasure cities" built by the captive Israelites for Pharaoh. The archaeological interest which has always surrounded the locality of this city was renewed by the publication of *The Store City of Pithom and the Route of the Exodus*, by Edouard Naville, of the Egyptian exploring expedition, 1885. It is shown by reasonably conclusive evidence that the modern settlement of Tell-el-Maskhûtah is the site of the ancient Succoth. The "stone of Pithom," unearthed by M. Naville, is as important a discovery as was that of the Rosetta stone, as it bears strong testimony to the identification of the modern with the ancient site. On this stone the god Sept is called "the great god of Succoth;" Rameses II. is styled "the lord of Succoth;" another inscription reads: "All the priests who go into the sacred abode of Tam, the great god of Succoth;" finally, the hawk of black granite engraved on the stone, and known to have been the emblem of Harmechis, with the oval of Rameses II., seems to confirm the biblical record, and to fix the date at that given by Old Testament scholars as the time of the building of the city. The hieroglyphic form of the name is Thurku, or Thukut, which, by well-understood philological laws, was rendered Succoth by the Hebrews. It is also discovered that Tell-el-Maskhûtah is the site of the Heroopolis of the Greeks.

SUCHET, LOUIS-GABRIEL, Duke of Albufera, and marshal of France, was descended from an honorable family, and b. at Lyons, Mar. 2, 1770. He volunteered as a private into the cavalry of the Lyons national guard in 1792, and subsequently became attached to the army of Italy. His rare intelligence and brilliant valor, displayed at Lodi, Rivoli, Castiglione, Arcola, and in numerous battles of less note, laid the foundation of his military reputation, and in 1798 he became gen. of brigade. The able manner in which he, with a force not one-sixth of that of the Austrians, kept Melas in check (1800), preventing the invasion of the s. of France, and ultimately capturing 15,000 prisoners, is one of the most brilliant military feats on record. Suchet also took a distinguished part in the campaigns against Austria (1805) and Prussia (1806), and was subsequently (April, 1809) appointed generalissimo of the French army in Aragon, where, for the first time, he appears as holding an independent command. The part of Spain committed to his charge, though inhabited by a people distinguished by their obstinacy and patriotism above all others in Spain, was completely subdued, more, however, through his just and able administration, and the strict discipline which he maintained, than by military talent. The latter quality he was only called upon to exercise against Spanish troops, which he had little difficulty in annihilating. In the first few days of 1812 he conquered Valencia, and obtained in addition to his dignity of marshal (July 8, 1811) that of duke of Albufera, and the grant of a magnificent domain. The five campaigns which he made in the peninsula are considered perfect models of the kind of service he had to perform—viz., to rivet the chains of a foreign domination on the necks of a patriotic and high-spirited people. The details have been well given by him in his *Mémoires sur ses Campagnes en Espagne* (Paris, 1829–34, 2 vols. with atlas). But the misfortunes of the other French armies in Spain compelled Suchet gradually to relinquish all his conquests. He was created a peer by Louis XVIII., but took service under his old master after his return from Elba, and was charged with the defense of the s.w. frontier. Deprived of his peerage at the second restoration, he did not return to court till 1819, when it was restored, and he soon rose high in royal favor. He died at the château of Saint Joseph, near Marseilles, Jan. 3, 1826. Napoleon's high opinion of Suchet's military talents is recorded by O'Meara and Las Casas, and, according to his classification, Suchet ranked second, Massena being first.—His son and successor in the dukedom of Albufera was a member of the corps législatif, and a supporter of the Napoleonic policy under the emperor Napoleon III.

SUCKER STATE. See STATES, POPULAR NAMES OF.

SUCKING-FISH, a name sometimes given to the remora (q.v.), and to fishes of the family discoboli (q.v.), which have a sucker formed by the union of the ventral fins, and are capable of attaching themselves by it to stones or other substances. The best known of the British species, and the only one which is of any value as an article of food, is the lump sucker (q.v.).

SUCKLING, Sir JOHN, one of the brilliant cavalier poets of the court of Charles I., was born at Whitton, in Middlesex, and baptized Feb. 10, 1608–9. His father, also a knight, held office as a secretary of state, and comptroller of the household, but died in 1627, when the poet was in his eighteenth year. The latter inherited large estates; and having completed his education at Trinity college, Cambridge, he went abroad, and served for some time in Germany under Gustavus Adolphus. He returned about 1632, and was soon distinguished for his wit, gallantry, and lavish expenditure. To aid the king against the Scots he raised a troop of 100 horsemen, whom he clad in a rich and gaudy uniform of white and red, with plumes of red feathers in their caps. This loyal corps is said to have cost the poet about £12,000. They rode n.; but no sooner had the cavalry come within sight of the Scots' army at Dunse than they turned and fled without aiming a blow! This disgrace gave occasion to numerous lampoons, and to a clever though coarse ballad against Suckling's gay horsemen; but in reality they behaved no worse than the rest of the English army. Their loyal commander next joined in a scheme to rescue Strafford from the Tower, and this being discovered, he fled for safety to the continent. He died, while yet in the flower of his life and genius, in 1641 or 1642. Various accounts are given of the circumstances attending his death, but the most painful of these, viz., that he poisoned himself in Paris, is confirmed by family tradition. See the memoir by the Rev. Alfred Suckling (1836), prefixed to a volume of *Selections from the Works of Sir John Suckling*. He had probably run through his fortune, and dreaded want, as well as despaired of the success of the royal arms. The works of Suckling consist of four plays, now utterly forgotten, a prose treatise entitled *An Account of Religion by Reason*; a collection of *Letters*, written in a stiff, artificial style; and a series of miscellaneous poems, beginning with *A Session of the Poets*, published in 1637, which is original in style, and happily descriptive of the author's contemporaries. But the fame of Suckling rests on his songs and ballads, which are inimitable for their ease, gayety, and pure poetic diction. His ballad of *The Wedding* is still unsurpassed, and one simile in his description of the bride—

Her feet beneath her petticoat,
Like little mice, stole in and out,
As if they feared the light—

has had the honor of being copied by Herrick and Congreve.

SUCRE. See CHUQUISACA.

SUCRÉ, ANTONIO JOSÉ DE, 1793-1830; b. Venezuela; educated at Caracas. When 18 years old he entered the patriot army, and in 1822 held a command at Pichincha. In 1823 he became the chief of the Peruvian patriots, and the next year won the battle of Ayacucho, which brought about the independence of Peru. By the legislature of Bolivia he was chosen president for life in return for his efforts in rendering that republic free. In 1827 an insurrection took place in which Sucre was wounded. He then resigned, engaged in the war between Colombia and Peru, and defeated the Peruvian army under Lamar at Tarqui, 1829. He was chosen president of the first congress of the republics which met in Bogota, 1830, and on his return was assassinated, it was said, by order of Obando.

SUCTORIA, an order of insects, containing only those forming the Linnæan genus *pulex*. See FLEA.

SUDAMINA, or MILIARY ERUPTION, is one of the diseases of the skin belonging to the class *vesicule*, or *vesicles*. The former name is derived from the fact that the disorder is always accompanied with profuse sweating; while the latter has reference to the size of vesicles, which do not exceed those of a millet-seed. The vesicles are most abundant on the neck and trunk, and are sometimes, but not always, attended with itching. They almost always occur in association with febrile disorders, which, however, do not seem in any way modified by these occurrences. The only known condition that favors their production is copious and prolonged sweating. They sometimes appear in health during the summer heat, when strong exercise has induced copious sweating. Pathologically this disease is of so little importance that it is unnecessary to notice its treatment. It is, however, sometimes useful as a sign in diagnosis, especially in typhus and typhoid fevers.

SUDAN. See SOODAN.

SUDBURY, a municipal borough of Suffolk, 16 m. s. of Bury St. Edmunds, on the left bank of the Stour, across which a bridge connects the town with the suburb of Balingdon in Essex. The silk and bunting manufactures are the most important branches of industry. There are also brick-works, in which the white clay used is notable for its purity. Malting is carried on. Sudbury was one of the first towns into which the woolen manufacture was introduced by the Flemings. Pop. '81, 6584; '91, 7059.

SUDDEN DEATH may be induced by natural or by violent causes, and the detection of the true cause is obviously of very great importance, since the acquittal or conviction of a suspected person may depend upon it. Sudden death may occur naturally from syncope (fainting or swooning), from asphyxia (literally pulselessness), or, more correctly, apnæa (privation of breath), or from coma (insensibility). Syncope, or sudden cessation of the heart's action, may occur, as Dr. C. J. B. Williams points out in his *Principles of Medicine*, in two ways: (1.) By the heart losing its irritability (or becoming paralyzed), so that it ceases to contract; and (2.) by its being affected with tonic spasm, in which it remains rigidly contracted, losing its usual alternation of relaxation. Sudden death from asphyxia, or, more correctly, from apnæa, occurs when, from any cause, the entrance of air into the lungs is prevented. It is not so often witnessed as a result of disease as of accident. It is sometimes caused by a spasmodic closure of the chink of the glottis (see LARYNX). Sudden death from coma is liable to occur in apoplexy and injuries of the head.

In its relations to medicine and medical jurisprudence the subject of this article has been fully discussed by Herrick and Popp, *Der plötzliche Tod aus inneren Ursachen* (1848).

SUDERMANN, HERMANN, German author, born at Matzicken, in East Prussia, Sept. 30, 1857. After attending the universities of Königsberg and Berlin, he decided to devote himself to literature, and for some years was editor of a small newspaper, the *Deutsches Reichsblatt*. During this first period he wrote a large number of stories which passed unnoticed, and of plays which were never produced. But the production in 1888 of his social drama *Ehre*, in which he identified himself with the naturalistic movement, met with a remarkable success, and brought him into the front rank of contemporary German writers. He has since published a long line of novels and short stories, *Frau Sorge* (1888); *Der Katzensteg* (1889); *Im Zwielicht* (1890); *Iolanthes Hochzeit* (1893); *Es War* (1894), which have all gone through numerous editions; also a tragedy, *Sodom's Ende* (1890); and the following plays, *Heimat* (1893); *Die Schmetterlingsschlacht* (1894); *Das Glück im Winkel* (1895); *Morturi* (1896). The success of *Ehre* was repeated only in *Heimat*, which under the title of *Mayda* has gained widespread fame as a favorite rôle of both Eleanora Duse and Sarah Bernhardt.

SUDETENGEIRGE, the most important mountain-range of Germany, dividing Prussian Silesia and Lausitz from Bohemia and Moravia, and connecting the Carpathians with the mountains of Franconia. It does not form a continuous chain except in the middle, where it is known under the names of Riesengebirge (q.v.) and Isergebirge; the ends, both toward the n.w. and s.e., broadening out into great rugged hilly plateaus, with broken chains and isolated peaks. The Sudetengebirge are composed chiefly of granite, gneiss, mica-schist, and porphyry, with superimposed beds of basalt and coal, and are clothed with pines to a height of between 2,000 and 3,000 feet. They are rich in minerals, especially in the metals, iron, lead, copper, zinc, tin, cobalt, with some silver and gold. Schneekoppe (Snow-peak) in the Riesengebirge, about 5,000 ft. high, is the cul

minating point in the whole range.—The name Sudetengebirge is applied in a narrower sense to the s.e. portion of the range separating Silesia from Moravia.

SU'DRA is the name of the fourth caste of the Hindus. See **CASTE**.

SUE, MARIE JOSEPH EUGÈNE, a well-known French novelist, was born at Paris Dec. 10, 1804. His father, Jean-Joseph Sue, was one of the household physicians of Napoleon, and he educated his son for his own profession. At the age of twenty the young man became an army-surgeon. In this capacity he served in the French expedition to Spain, under the duke of Angoulême, in 1823. Subsequently he transferred himself to the navy; and in 1828 was present at the battle of Navarino. In 1829 his father died, leaving him a handsome fortune, on the acquisition of which he ceased to practice his profession. After coquetting a little with art he betook himself seriously to literature, and very soon, in the department of fiction, he achieved a considerable popularity. His earlier efforts were sea-stories, somewhat after the manner of Cooper, or romances in imitation of Scott; and though in both fields he displayed talent, his true power was scarcely as yet developed. Something of it may, however, be traced in his *Mathilde, ou les Mémoires d'une Jeune Femme*, published in 1841; but it was first decisively made manifest in the famous *Mystères de Paris*, which began to appear the year after in the columns of the *Journal des Débats*. The furor of excitement occasioned by this work and its successor—*Le Juif Errant*—which appeared in the *Constitutionnel*, not only in France but elsewhere, has seldom, perhaps, been exceeded; and for both the writer received large sums of money. In 1846 his *Martin, l'Enfant Trouvé* was issued; in 1847-8 appeared *Les Sept Péchés Capitaux*; and in 1852 he published *Les Mystères du Peuple*, his last work of any importance. Throughout Sue's latest works there runs a vein of socialism; and at the revolution of 1848 he allied himself with the extreme sect of the republicans. On April 28, 1850, he was elected deputy to the legislative assembly for the department of the Seine, and was assiduous in his duties as such till the *coup d'état* of Dec., 1852, by which he was driven into exile. He retired to Savoy; and at Annecy he died July 3, 1857.

In the writings of Sue great power is displayed; but it is rather of the unhealthy kind, and depends for much of its effect on vicious sources of interest. His books are read once with a fever-heat of curiosity, and scarcely bear reproof.

SUE'CA, a t. of Spain, in Valencia, and 23 m. s. of the city of that name, on the Jucar, about 4 m. from the Mediterranean. Brick and tile works are in operation, and there are several flour and rice mills. Pop. 11,340.

SU'ET is a variety of solid fatty tissue, which accumulates in considerable quantity about the kidneys and the omentum of several domestic animals, especially the ox and sheep. Beef suet is extensively used in cookery, while purified mutton-suet under the name of *Sevum Præparatum* occurs in the Pharmacopœia, and is obtained by melting and straining the internal abdominal fat. It consists of a mixture of ordinary animal fats with a great preponderance of the most solid of them, viz., stearin, which constitutes about three-fourths of the whole. The pure suet of the Pharmacopœia is "white, soft, smooth, almost scentless; and is fusible at 103°." It is used as an ingredient in cerates, plasters, and ointments. Ordinary melted suet is frequently employed in the same manner as lard, to preserve potted meats or fish and similar articles from the action of the air.

SUETO NIUS, GAIUS TRANQUILLUS, son of Suetonius Lenis, a tribune of the 13th legion under Otho, was born probably a few years after the death of Nero. He is known to us chiefly as a Roman historian and miscellaneous writer, for his merits as which he is highly praised by the younger Pliny. He was also, it is supposed, a teacher of grammar and rhetoric, and a composer of exercises in pleading; nay, from a letter of Pliny's to him, it may be gathered that he sometimes pleaded causes in person. Pliny procured him the dignity of military tribune, which, by Suetonius's desire, he got transferred to another. Though childless, Suetonius was, through the same friendly agency, presented by Trajan with the *jus trium liberorum*, which, in that reign, was only to be had by great interest. He was afterward secretary of the emperor Adrian, whose favor he had secured. The date of his death is unknown. All his works (among which, as we learn from Suidas, there were several on topics usually treated by grammarians) have been lost, except his *Lives of the Cæsars*, his *Lives of Eminent Grammarians*, and (in part only) his *Lives of Eminent Rhetoricians*. It is by the first of these works that he is most favorably known, replete as it is with information about the twelve Cæsars, from C. Julius to Domitian, which is to be had nowhere else, and abounding with anecdotes which, while they too often prove the profligacy of his heroes, testify to the impartiality of their chronicler. From a period long before the renaissance to the present, these "Lives" have always been favorite reading, and have found numerous editors, the best of whom is still Burmann (Amsterdam, 1736), and numerous translators into nearly every European language. The standard text is that of Roth (Leips. 1836).

SUE VI, first mentioned by Cæsar, in whose history (*De bello Gallico*) the name is employed as the collective designation of a great number of Germanic peoples. They occupied a district of indefinite extent on the eastern side of the Rhine, and may have been the same tribes as those subsequently known as Chatti, Longobardi, etc. Cæsar

states that their territory comprised 100 cantons, and was densely wooded, that they had towns (*oppida*), but no strongholds, and that every year a part of the population left their homes to seek employment in war. The Suevi of whom Tacitus speaks (*Germania*, 38, etc.) seem to have dwelt n. and e. of the Suevi of Cæsar, extending as far as the Elbe and the Baltic, which Tacitus calls the "Suevic sea." The peoples united under the rule of Maroboduus, the Marcomannic chief, were Suevic, and hence the Marcomanni and Quadi, who figure in the reigns of Marcus Aurelius and Aurelian, are often called Suevi. After the name had fallen into disuse as a collective designation, it re-appeared (second half of the 3d c., *Amm. Marc.*, etc.) as the name of a people occupying the same territory as the Suevi of Cæsar, who appear, however, to have been a mixed race made up of adventurers from different parts of Germany, and who probably took the name of Suevi after possessing themselves of the country. We find them in alliance with the Burgundians, Alemanni, Alani, Vandals, etc. They are among the most notable of the barbaric peoples that broke up the Roman empire in the n.w. and west. Bursting through the passes of the Pyrenees (409 A.D.), they along with the Vandals, overran and wasted Spain (q.v.). Those who remained at home in Germany seem to have spread during the 5th c. e. to the Neckar and the Rauhe Alps, and s. as far as Switzerland. The mediæval Swabians were their direct descendants.

SUEZ; until recently, a small, ill-built, wretched-looking town, on an angle of land near the northern extremity of the gulf of Suez, 76 m. e. of Cairo, with which it is connected by railway. The pop. was officially returned in 1882 as 10,919. It is walled on all sides but that toward the sea, has an indifferent harbor, but a tolerably good quay. Suez of late has been greatly improved. The town is divided into the Arab quarter, with seven unimportant mosques, and the regularly laid-out European quarter, with the store-houses of the Peninsular and Oriental Steamship Co. The bazars are provided with clarified butter from Sinai, with fowls, grain, and vegetables from the Egyptian province of Sharkijeh, and with wood, dates, and cotton. Rain falls but seldom, sometimes not once in three years. All around stretches a burning waste of sands. Suez owes its modern prosperity to the establishment of what is known as the *overland route* (q.v.) to India, in consequence of which a large portion of the traffic between England (and other European countries) and the east passes through the place; and to the opening of the Suez canal in 1869. For a long time previous to the establishment of the overland route, Suez had been in a state of complete decay, although, at a yet earlier period—previous, in fact, to the discovery of the sea-route to India by the cape of Good Hope—it was a flourishing emporium of the products of east and west. A salt manufactory has been established here by the Egyptian government, and sends every year very large exportations of its product to India.

The **GULF OF SUEZ** is the western and larger of the two branches into which the Red sea divides toward its northern extremity, and washes on the w. the coasts of Egypt, on the e. those of the Sinaitic peninsula. Extreme length, 200 m.; average breadth, about 20 miles. The shores are sometimes low, barren, and sandy wastes, sometimes bold and rocky headlands.

The **ISTHMUS OF SUEZ** is a neck of land 72 m. in width at its narrowest part, extending from the Gulf of Suez on the s. to the Mediterranean on the n., and connecting the continents of Asia and Africa. It embraces within its limits (according to the commonly received opinion) the fertile Goshen (q.v.) of antiquity; but it is now a wretched uninhabitable waste, consisting of mingled sand and sandstone, interrupted here and there with salt swamps or lakes, but almost entirely destitute of fresh water. The main interest that attached to this region, in recent times, was, whether or not—since Egypt was on the great highway to India and China—it was practicable to cut a ship-canal through the isthmus. We shall here briefly indicate the main steps that were taken to have this important question solved in a satisfactory manner.

It is certain that, in ancient times, a canal connecting (indirectly) the two seas did exist. At what period it was constructed is not so certain. Herodotus ascribes its projection and partial execution to Pharaoh Necho (about 600 years B.C.); Aristotle, Strabo, and Pliny less felicitously fix on the half-mythical Sesostris as its originator. The honor of its completion is assigned by some to Darius, king of Persia, by others to the Ptolemies. It began at about a mile and a half from Suez, and was carried in a north-westerly direction, through a remarkable series of natural depressions, to Bubastis, on the Pelusiac or eastern branch of the Nile. Its entire length was 92 m. (of which upward of 60 were cut by human labor) its width from 108 to 165 ft., and its depth 15 (Pliny says 30) feet. How long it continued to be used, we cannot tell; but at length it became choked up with sand, was restored by Trajan early in the 2d c. A.D., but again became unusable from the same cause, and so remained till the conquest of Egypt by Amrou, the Arab general of the Calif Omar, who caused it to be reopened, and named it the "Canal of the Prince of the Faithful," under which designation it continued to be employed for upward of a century, but was finally blocked up by the unconquerable sands, 767 A.D. In this condition it has ever since remained. The attention of Europe was first turned to it in modern times during the invasion of Egypt by Bonaparte, who caused the isthmus to be surveyed by a body of engineers, who arrived at the opinion that the level of the Mediterranean is 30 ft. below that of the Red Sea at Suez, an opinion

which a subsequent survey proved to be erroneous. From this time, the question continued to be agitated at intervals, especially by the French, and various plans were proposed, but nothing definite was arrived at till 1847, when France, England, and Austria sent out a commission to measure accurately the levels of the two seas. The commissioners, M. Talabot, Mr. Robert Stephenson, and Signor Nigrelli, ascertained that, instead of a difference of 30 ft., the two seas have *exactly the same mean level*. The only noticeable difference was, that there is a tide of $6\frac{1}{2}$ ft. at the one end and $1\frac{1}{2}$ ft. at the other. Another examination leading to similar results was made in 1853. Mr. Stephenson expressed himself very strongly against the feasibility of a canal, that is to say, a canal of such dimensions as would suit the requirements of modern commerce, and planned, instead, a railway from Cairo to Suez, which was opened (1858), and which now conveys overland all the Indian and Australian mails. The French, however, were not satisfied with Mr. Stephenson's conclusions, and M. Talabot, on his return to Europe, published in the *Revue des Deux Mondes* a plan for connecting the two seas by way of Alexandria and Suez (or rather a point 6 m. below Suez), for a description of which we have not space. In 1854 a new experimenter appeared in the person of M. de Lesseps, a member of the French diplomatic service in Egypt, who (1856) obtained from the pasha the "concession," i.e., the exclusive privilege of forming a ship-canal from Tyneh (near the ruins of ancient Pelusium) to Suez. The peculiarity of M. de Lesseps's plan lay in this, that, instead of following an oblique course, and uniting his canal with the Nile, as the ancients had done, and as all the modern engineers had thought of doing, he proposed to cut a canal right through the isthmus in a straight line to Suez. This canal was to have a minimum width at the surface of 262 ft., and at the bottom of 144 ft., with a depth of $22\frac{1}{2}$ ft.; and at each end there was to be a sluice-lock formed, 330 ft. long by 70 wide. By taking advantage of the tides at Suez, it was hoped that an additional depth of 3 or 4 ft. might be obtained. But the colossal feature of M. de Lesseps's plan was the artificial harbors which he proposed to execute at the two ends, Tyneh and Suez. That at the Mediterranean end was to be carried out 5 m. in order to obtain a permanent depth of water for a ship drawing 23 ft., on account of the enormous quantity of mud-sand which the Nile annually pours out (30,000,000 cubic yards, it is said), and which the prevalent wind drives eastward along the shore toward the southern coast of Palestine. The quantity of stone required to construct this harbor has been calculated variously at from 3 to 12 million cubic yards, and there are no stone quarries except at a great distance from Tyneh. The pier at Suez was to be carried out 3 m., and in other respects the difficulties, though great, were not, as on the Mediterranean coast, *almost insurmountable*. The English for political, perhaps, as well as for practical reasons, looked with aversion on M. de Lesseps's scheme; but in 1855, the question was again taken up in an international spirit, a new European commission was appointed, which reported that M. de Lesseps's scheme, somewhat modified, *was practicable*, and that a canal might profitably be constructed. The result of the report was the formation of a joint-stock company, with a subscribed capital of £8,000,000 (afterward increased), in which Saïd, the pasha of Egypt, took a large number of shares, and made large concessions of land; and the work was accordingly begun. The canal was to be dredged through lake Menzaleh, which runs far into the land directly toward Suez, to be connected with lake Temsah, the Bitter lake, and other marshy swamps, and so with Suez. Only a third of the way required to be excavated through the sands and rocks of the desert. As early as Dec., 1864, the Mediterranean and the Red sea had been connected. The communication, however, was not throughout by the permanent maritime canal, but simply by a fresh-water canal of no great width or depth. In April, 1865, the works, at the request of M. de Lesseps, were visited by another scientific commission, who reported more favorably of the scheme than was expected in England. They stated that the "construction of a ship-canal across the isthmus is only a question of time and money," and they added that three years would suffice for the completion of the various contracts connected with the undertaking.

The canal was formally opened in Nov., 1869. An account of the opening, and a description of the canal in its completed state, is given under SUEZ CANAL.

The hostility of the British nation to the canal faded away with its successful completion and the advantages which it afforded to British commerce. The fears expressed at the opening of the canal, that the trade of the east would be diverted from Great Britain as a center, were found by statistics to be groundless. In 1875 the British government purchased, for \$20,000,000, the Khedive of Egypt's shares in the canal, which amounted to 176,602 out of 400,000. These shares gave no returns to their owner till 1894, the Khedive having alienated the dividends till that period in favor of the company.

SUEZ CANAL. In the former article on this subject, the nature of the scheme was briefly described; and the progress of the works noticed down to the year 1865. In this place, some of the features will receive a little further explanation, now that the canal is finished and in operation. The canal is 100 m. long, 25 m. being through lakes.

The Port Saïd Entrance.—Port Saïd or Saïd, a t. now containing 10,000 inhabitants, had no existence in 1860. It became the depot of the company, the metropolis of vast bodies of laborers and other persons employed on the works of the canal. As the Mediterranean sea is very shallow near this point, an artificial deep channel had to be made,

bounded e. and w. by piers stretching far out into the sea. Stone for these piers was, in the first instance, brought from a long distance; but afterward artificial stone was made on the spot, consisting of two parts of sand and one part of hydraulic lime ground into a paste, and poured into wooden boxes or moulds. When the mixture solidified, the mould-boards were removed, and the solid blocks of artificial stone were left from three to six months in the open air to dry and harden. The blocks contain 10 cubic meters each, weigh 20 tons, and were made at a contract price of 42 francs per *mètre cube*. The western pier has a length of 7,000 ft., and the eastern of 6,000 ft.; they are 4,600 ft. apart at the shore, but gradually approach toward each other, so that their outer ends are only 2,300 ft. apart. The western pier is continued in an arc of 1100 yds. extent, so as, with the eastern pier, to shelter the harbor from all winds. Within this outer harbor is an inner port, 870 yds. by 500, which is kept at a uniform depth of 30 ft., by means of steam-dredging. The lighthouse, with its electric light, is 180 ft. high.

From Port Said to Temsah Lake.—From Port Said, the canal crosses about 20 m. of Menzaleh lake, a salt-water shallow, closely resembling the lagoons of Venice, having from 1 to 10 ft. depth of water. The canal through this lagoon is 112 yds. wide at the surface, 26 yds. at the bottom, and 26 ft. deep. An artificial bank rises 15 ft. on each side of this channel. Beyond Menzaleh lake, heavier works begin. The distance thence to Abu Ballah lake is 11 m., with a height of ground above the level of the sea varying from 15 to 30 ft. Crossing the last-named lake, there is another land distance of 11 m. to Temsah lake, cutting through ground to a depth varying from 30 to 70 or 80 ft.; and then 3 m. further across this little lake itself. At El Guisr, or Girsch, occurs the deepest cutting in the whole line, no less than 85 ft. below the surface; at the water-level it is 112 yds. wide, at the summit-level 173 yds., from which the vastness of the gap may be estimated. Ismailia (pop. 5,000) on Temsah lake, is regarded as the central point of the canal. While the canal was being made, it grew up rapidly from an Arab village to a French town, with the houses of engineers and managers, hotels, shops, cafés, a theater, and a central railway station, from which railways stretch to Alexandria and Suez.

The Fresh-water Canal.—This extends from the Nile to Temsah lake, and was constructed purposely to supply with water the population accumulating at various points on the line of the canal; but is also used by small sailing-vessels. This fresh-water or "sweet-water" canal comprises three portions or sections: (1) from the Nile e. or n.e. to Ismailia, on Temsah lake; (2) from Ismailia, nearly s. to Suez, on the western side of the great ship or maritime canal; (3) from Ismailia nearly n. to Port Said, also on the w. side of the ship canal. The first and second of these sections are really canals, large enough to accommodate small steamer and barge traffic; but the third section consists simply of a large iron pipe, through which the water is conveyed to the several stations. Plugs are inserted in the pipe wherever needed, to allow water to be drawn off for everyday wants.

From Temsah Lake to Suez.—The route crosses Temsah lake to Toussoum and the Serapeum cutting, through a plateau 46 ft. above the sea, where the waters were let in by the prince and princess of Wales, Feb. 28, 1869. There is a space of 8 m. from Temsah lake to the commencement of the Bitter lakes, which had to be dug to a depth varying from 30 to 62 ft., according to the undulations of the surface. In these deep cuttings, owing to the great width of the canal, the quantity of sand to be dug out (for it is nearly all sand, though sometimes agglomerated with clay) was enormous, requiring the constant labor of a large number of powerful dredging machines and elevators. In passing through the Bitter lakes, there was more embanking than excavating to be done, seeing that the bottom of this region is only two or three yards above the intended bottom of the great canal. From the southern end of the Bitter lakes to Suez, a distance of about 13 m., there is another series of heavy cuttings through the stony plateau of Chalouf, varying from 30 to 56 ft. in depth. Where cutting is thus difficult, the surface width is reduced considerably from the regular width of 327 feet. The canal is intended throughout to be 72 ft. wide at the bottom, and 26 ft. deep.

On Nov. 16, 1869, the Suez canal was opened in form, with a procession of English and foreign steamers, in presence of the Khedive, the empress of the French, the emperor of Austria, the crown-prince of Prussia, and others. On Nov. 27, the *Brazilian* went through; a ship of 1809 tons, 380 ft. long, 30 ft. broad, and drawing from 17½ to 20½ ft. of water. Since then, the canal has continued in successful operation, and passages have been made almost daily, chiefly by British vessels. The cost of construction of the canal was said to have reached in Dec. 1869, the total of \$58,135,000. In 1870, 491 ships, of 436,618 tons, passed through; and in 1895, 3434 ships, of 8,448,383 tons. The larger part of the shipping belongs to Great Britain. The great advantage of the canal is, of course, the shortening of the distance between Europe and India. From London or Hamburg to Bombay is by the cape about 11,220 m., but by Suez only 6332; that is, the voyage is shortened by 24 days. From Marseilles or Genoa there is a saving of 30 days; from Trieste, of 37. The rate at which steamers are allowed to pass through, is from 5 to 6 knots an hour. The canal charges are, 10 francs per ton, and 10 francs per head for passengers. The transit receipts for 1895 amounted to 78,426,000 francs. To secure uninterrupted sailing, enlargement of the canal was begun in 1884; an additional breadth of 262 feet, it was believed, would increase the speed of vessels to 8½ knots an hour.

SUFFIELD, a town in Hartford co. Conn.; on the Connecticut river and the New York, New Haven and Hartford railroad; 17 miles n. of Springfield. It was incorporated in 1674 by Massachusetts, and annexed to Connecticut in 1749. The principal industries are farming, tobacco growing, and cigar making. It has a public library, literary institute, water works supplied from artesian wells, national and savings banks, and several churches. The assessed property valuations exceed \$2,000,000. Pop. '90, 3169.

SUFFOCATION. See ASPHYXIA and RESPIRATION.

SUFFOLK, a co. in e. Mass., on Massachusetts bay, containing the cities of Boston and Chelsea, the townships of Revere and Winthrop, and some small islands in Boston harbor and Massachusetts bay; 45 sq. m.; pop. '90, 484,780. Co. seat, Boston.

SUFFOLK, a co. in s.e. New York, bounded on the n. by Long Island sound, on the s. by the Atlantic ocean, watered by the Peconic and other rivers, traversed by branches of the Long Island railroad; area, 720 sq.m.; pop. '90, 62,491, chiefly of American birth. It includes the central and e. portions of Long Island. The surface is level except in the north. Co. seat, Riverhead.

SUFFOLK, a maritime co. of England, bounded on the e. by the German ocean, on the n. by Norfolk, and on the s. by Essex. Area, 947,681 acres; pop. '91, 371,235. The surface is for the most part flat, falling away into marshes on the n.w. and n.e. borders. The coast-line, which is low and marshy, or lined with cliffs of shingle or gravel and red loam, is about 50 m. in length, and is, on the whole, regular, being unbroken by any considerable indentation, and comprising no headland worthy of notice except Lowestoft Ness, the most easterly point in Great Britain. The tributaries of the Waveney, which separate Suffolk from Norfolk on the n., and those of the Stour, which form the boundary-line on the s., together with the river Lark, an affluent of the Great Ouse, and the Gipping, which, after it begins to broaden into an estuary, is called the Orwell, are the chief streams. The climate is cold in spring, but is drier than that of the western counties. The soil is of various kinds, some of which are very productive. Most of the land is under cultivation, and the most improved system of agriculture has been introduced, together with the best and newest agricultural implements. A polled breed of cattle, of which the cows are deservedly held in high esteem, is peculiar to the county. The Suffolk pigs are a famous and most profitable breed. The ordinary crops are raised. The co. is divided into six parliamentary districts. Capital, Bury St. Edmunds.

SUFFRAGAN (Lat. *suffraganeus*, from *suffragium*, a suffrage or vote), the name given to a bishop in a province, in his relation of dependence or subordination to the archbishop, or rather metropolitan, of the province. See METROPOLITAN. In some continental churches, the name is applied to coadjutor-bishops appointed—as in the case of prince-bishops in the German empire—to assist the bishop in his own diocese.

SUFFRAGE (Lat. *suffragium*, derivation uncertain), a right to vote, and more particularly the right possessed by the citizen of a state where representative government exists to vote for a member of the legislative body.

The idea that the universal enjoyment of political suffrage is a right by natural law is grounded on the fiction that the obligations of municipal law arise out of a social contract express or implied. In opposition to this notion it is argued that the true purpose for which government exists is the general welfare of the nation; and it is the duty of state to consider whether the suffrage may be more beneficially exercised by the many or the few. Infants, minors, idiots, and insane persons have everywhere been excluded from the suffrage, on the ground that sound judgment is necessary for its exercise. Persons convicted of crimes have been excluded, as a security to society; and also almost universally women, for reasons based on their relation to society and to the opposite sex. Like considerations of expediency, it is argued, are a ground for withholding the suffrage from those whose circumstances and station in life render it unlikely that they should form a sound judgment on political questions. It is the intelligence and enlightenment of the country that an elective legislature should represent; and in any large extension of the suffrage there is obviously a risk of the intelligence of a constituency being swamped by its mere numerical majority. A widely extended suffrage has, however, been advocated as a valuable means of educating the people to self-dependence; and several philosophical politicians of the present day, who are favorable to a large extension of the electoral qualification, propose to obviate what they regard as its otherwise inevitable evils by graduating the suffrage, so as to give each individual elector a number of votes corresponding as much as possible to his property, education, or social position. Schemes for this end, differing in detail, have been proposed by Mr. J. Stuart Mill, in his *Considerations on Representative Government* (1851); and by Prof. Lorimer in his *Political Progress not necessarily Democratic* (1857), and *Constitutionalism of the Future* (1865). See REFORM, REPRESENTATION, BALLOT.

Suffrage, under the United States constitution, is exercised by such electors in each state as have the qualifications necessary for electors of the most numerous branch

of the state legislature (art. 1, sec. 2). By the XIV. and XV. amendments the states are forbidden to abridge the privileges or immunities of United States citizens (see PRIVILEGES AND IMMUNITIES), or to deny or abridge the right of suffrage on account of "race, color, or previous condition of servitude." It seems clear that the states retain the right to impose conditions on suffrage other than those specifically prohibited in the amendments. The age of 21 is universally fixed on as that when suffrage may be exercised by male citizens; conviction for crime, insanity, and pauperism everywhere excludes. In a few states ability to read and write is required, while Rhode Island has a small property qualification. Wyoming territory, 1885-87, allowed women to vote in local matters, and Massachusetts in 1879 passed a law allowing women to take part in the town election of school officers; some other states have similar provisions.

SUFISM (from *sufi* or *sofi*, the Greek *sophos*, a sage; erroneously also derived from Arab. *sof* or *suf*, wool, and thus designating an individual who wears nothing but woolen garments) designates a certain mystic system of philosophical theology within Islam. Its devotees form a kind of ecclesiastical order somewhat similar to that of the fakirs (q. v.), or dervishes, but they are mostly of a far superior stamp; and some of the greatest Persian poets, philosophers, historians, and even kings belonged to their ranks. They assume four principal degrees of human perfection or sanctity. The first or lowest is that of the shariat—i. e., of the strict obedience to all the ritual laws of Mohammedanism, such as prayer, fasting, pilgrimage, almsgiving, ablutions, etc., and the ethical precepts of honesty, love of truth, and the like. The second degree (*tarik*) is not attainable by all, but only by those higher minds that, while strictly adhering to the outward or ceremonial injunctions of religion, rise to an inward perception of the mental power and virtue necessary for the nearer approach to the divinity, the necessity of, and the yearning for, which they feel. The third (*hakikal* = truth) is the degree of those who, by continuous contemplation and inner devotion, have risen to the true perception of the nature of the visible and the invisible—who, in fact, have recognized the Godhead, and through this knowledge of it have succeeded in establishing an ecstatic relation to it. This state is finally sublimated into that highest and last degree (*maarifal*), in which man communicates directly with the Deity. Practically, the great mass of the people take the lowest degree; the second stage is reached by the "*murides*," who do not fulfill the behests of the ceremonial law because they are behests, but because they are good in themselves, knowing that virtue is good; and because it leads to truth, they adhere to it for its own sake. They give alms because the sight of poverty grieves them; their ablutions are as much due to their desire of physical purity as to that of obeying a religious injunction. The third stage is that of the *naibs*, to whom all this spiritualizing of faith applies in a still more eminent degree. And the highest stage of attainable perfection is that of the *murshid*, whose words are God's words, pure and simple, because he is in direct and constant communion with God. He is the "*sun of faith*," by whose reflected light shine the *naibs*, its "*moons*." All Sufistic poetry and parlance is to be taken allegorically and symbolically. They represent the highest things by human emblems and human passions; and religion being with them identical with love, erotic terminology is chiefly used to illustrate the relation of man to God. Thus the beloved one's curls indicate the mysteries of the Deity; sensuous pleasures and chiefly intoxication, indicate the highest degree of divine love as ecstatic contemplation; while the wine-house, of which constant mention is made, merely indicates the state in consequence of which our human qualities merge in or are exalted into those of the Deity. Founded in the 9th c. by Kafi-Mullah, this peculiar mysticism has principally struck root in Persia, and chiefly among men of genius, e. g., Hafiz (q. v.). Recently, it has been revived, with slight modifications, by Shamil, the renowned and once formidable antagonist of the Russians, who undertook to enlist even the common soldiers, if not in the ranks of the initiated—for Sufism, in its real meaning, is very exclusive—at least of its votaries; and the very lowest among them even had a sentence given him indicative of his forming part of the sect and of the gradations that form its main characteristic. In conclusion, it may be observed that Sufism mixes up all religions and all their prophets indiscriminately in one class; and the words idolatry, unbelief, licentiousness, and the like are generally used in their reverse sense by its votaries. Their principal religious writer is Jaleddin Rumi.

SUGAR (Lat. and Gr. *sacchar*-, Sans. *sarkara*, Pers. *schakar*, Arab. *sokkar* or *assokkar*, Sp. *azucar*, It. *zucchero*, Fr. *sucre*, Ger. *zucker*) is a general term applied by chemists to a number of neutral carbo-hydrates, possessing a more or less sweet taste, for the most part crystallizable, and produced by the vital processes going on in certain plants and animals. They are divisible into two groups, the first embracing such sugars as are capable of undergoing fermentation, and of being resolved, under the action of yeast, either directly or indirectly into alcohol and carbonic acid gas; and the second including those sugars which are not capable of being broken up by fermentation into the above-named products. The first group contains cane-sugar or sucrose, fructose or inverted sugar, trehalose, mycose, melezitose, melitose, grape-sugar or glucose (q. v.), and milk-sugar or lactose; while the second group includes inosite or inosin, sorbite or sorbin, scyllite or scyllin, and eucalyn.

Cane-sugar or *sucrose*, $C_{12}H_{22}O_{11}$, the ordinary sugar of commerce, is by far the most

important of this class of compounds; and in so far as its sweetening properties are concerned, it exceeds grape-sugar in the ratio of 5 to 2, and milk-sugar in a still higher ratio. It has a specific gravity of 1.6. It dissolves in about one-third of its own weight of cold water, producing a thick viscid syrup, and in all proportions in hot water; it is slightly soluble in absolute alcohol, but spirit of wine of specific gravity 0.830 dissolves about one-fourth of its weight. By the spontaneous evaporation of its watery solution it is deposited in four-sided rhomboidal prisms. Common loaf-sugar and sugar-candy are two well-known forms of crystallized sugar; the former consisting of a mass of small transparent crystals, and owing its dazzling whiteness to the numerous reflections and refractions which the rays of light undergo within the interior from the numberless crystals of which it is composed; while the brown color which the latter usually possesses is due to the coloring matter not having been removed from the syrup previous to crystallization. The crystals of sugar-candy are larger than those of loaf-sugar, in consequence of the slower evaporation in the former case. When crystals of sugar—as, for example, two pieces of loaf-sugar—are rubbed together in the dark, a pale phosphorescent light is evolved. If a solution of sugar be boiled for a long time it acquires an acid reaction and loses its power of crystallizing—a change which is attended by the assimilation of additional water, and the formation of the uncrystallizable inverted sugar which will be presently described. If the boiling be further prolonged the inverted sugar, $C_6H_{12}O_6$, assimilates more water, and is converted into grape-sugar, $C_6H_{12}O_6 + 2Aq$, while a little formic acid and ulmin (a brown, nearly insoluble substance belonging to the *humus* group) are produced. The crystallization of sugar is also prevented by the addition of a little oxalic, citric, malic, or any of the stronger acids to its solution; and in order to check the bad effects of an acid, a small quantity of lime is usually added to the cane-juice before it is heated.

The action of different degrees of heat on sugar has been carefully studied. At about $320^\circ F.$ ($160^\circ C.$) sucrose fuses, and on cooling forms the transparent amber-colored solid known as *barley-sugar*, which, if kept for a long time, assumes a crystalline state, and becomes opaque. If the application of heat be continued until about $410^\circ F.$ ($210^\circ C.$), the sugar loses two atoms of water, and *caramel*, which is described in the article *GLUCOSE*, is formed, and at a still higher temperature, the changes which sucrose undergoes are identical with those suffered by glucose. Sugar dissolves many metallic oxides when its solution is boiled with them—as, for example, freshly precipitated oxide of lead, lime, and baryta, and its presence prevents the precipitation by alkalies of several of the metallic oxides from their salts—the oxides of copper and of iron being thus retained in solution. Many metallic oxides are partially or entirely reduced when boiled with sugar; thus chromic acid is reduced to sesquioxide of chromium, salts of the red oxide of mercury are converted into those of the suboxide, and salts of gold give a precipitate of the reduced metal. It does not reduce alkaline solutions of oxide of copper to the suboxide (Trommer's test) unless with the aid of heat, which converts it into glucose. Under the action of certain oxidizing agents it may be converted into propionic, formic, and acetic acids. Sucrose is not *directly* capable of undergoing fermentation; but in the presence of a ferment (yeast, for example) it is converted into glucose, and in that form it readily undergoes vinous, lactic, and butyric fermentation. Its action on polarized light is described below.

This variety of sugar is chiefly obtained from the juice of the sugar-cane, but it is also abundantly present in the juices of certain species of maple and of beet-root, all of which yield this substance as a commercial product; it is also contained in sugar-grass (*sorghum saccharatum*), whose juice yields 13 per cent of sugar; in carrots and turnips, in the pumpkin, the chestnut, the young shoots of maize, in the flowering buds of the cocos palm, and in a large number of tropical fruits. Its use as an article of diet has been already mentioned under *Diet*. Several articles of food contain some form of sugar in considerable quantity. In peas, there are 2 per cent of sugar; in rye-meal and wheaten bread, about $3\frac{1}{2}$ per cent; in cows' milk, $4\frac{1}{2}$ per cent; in goats' milk and in barley-meal, $5\frac{1}{2}$ per cent; in human milk, in asses' milk, ripe gooseberries, and ripe pears, about 6 per cent; in oatmeal, about 8 per cent; in wheaten flour, from 4 to 8 per cent; in beet-root, from 5 to 10 per cent; in ripe peaches, $16\frac{1}{2}$ per cent; in ripe cherries, 18 per cent; and in dried figs, upwards of 60 per cent. Although sugar is commonly regarded as a luxury, it is in reality a very valuable article of food (as, indeed, might be inferred from its presence in milk, and in both the yolk and white of eggs), since it is very rapidly digested, and supplies heat-forming or respiratory food to the system, "When, however," says Dr. E. Smith, "it is compared with wheaten flour, it is a very dear food, since three or four times more carbon will be obtained for 1d. in flour, besides nitrogen, none of which is found in sugar. It has also been proved by Messrs. Lawes and Gilbert that even its fattening properties—that is to say, its power to form fat in the system, when it is supplied in excess of the quantity which the daily wants of the body require to produce heat—are not greater than those of starch as found in the cheapest grain."—*Practical Dietery*, 1863, p. 63. In consequence of sugar being a fat-forming substance, it should be taken very sparingly in cases of excessive obesity. There are certain forms of dyspepsia in which sugar should be avoided, as exciting increased gastric uneasiness; and in diabetes, all articles of food containing or (like starch) yielding sugar, should be rigidly prohibited. Although prone to fermentation when in a

dilute state, in its concentrated form sugar possesses great antiseptic power, and is extensively employed to preserve both vegetable and animal substances from decay. The sugar naturally existing in some fruits is often sufficient to insure their preservation in a dry state, while in other cases it is added, as in preserves and jellies. A mixture of salt and sugar applied to meat, fish, etc., preserves more of the natural flavor than mere salting does. Sugar converted into caramel is much used by cooks and confectioners as a coloring matter.

Closely allied in their chemical characters to sucrose are the following comparatively rare forms of sugar: (1) *Trehalose*, $C_{12}H_{22}O_{11} + 2H_2O$, so called from *Trehala*, or Turkish manna (the product of a coleopterous insect, *Larinus nidificans*), from which this variety of sugar is extracted, differs from sucrose in the following points—it crystallizes in brilliant rectangular octahedra; contains water of crystallization; fuses at 212° F. (100° C.), and loses its water of crystallization; is very soluble in hot alcohol; possesses about three times as great a rotatory power on polarized light; and when heated to 256° F. (130° C.), it loses its water of crystallization. (2) *Mycose*, obtained from ergot of rye, possesses the same composition as trehalose, from which it mainly differs in crystallizing in rhombic prisms, and in exhibiting a somewhat weaker rotatory power. (3) *Melcitose*, $C_{12}H_{22}O_{11} + H_2O$, obtained from larch manna, differs from cane-sugar in its less sweet taste, and in exhibiting a less powerful rotatory action. (4) *Melitose*, $C_{12}H_{22}O_{11} + 3H_2O$, the chief ingredient in the Australian manna yielded by the *eucalyptus* tree, crystallizes in acicular prisms, is feebly sweet, undergoes fermentation with yeast; but yields only half as much alcohol and carbonic acid as would be obtained from an equal weight of glucose, one half of this sugar being converted into an unfermentable syrupy body, known as *eucalym*, $C_6H_{12}O_6$.

More important than any of the above varieties, and differing from cane-sugar in a distinctive physical property, is the substance formerly known as *fruit sugar*, but now often described as *inverted cane-sugar*. The objection to the former name is, that the sugar contained in many ripe acidulous fruits, and formerly regarded as a distinct variety, is merely a mixture of cane-sugar, with more or less of the *inverted sugar*, $C_6H_{12}O_6$, which has already been noticed as resulting from the action of prolonged boiling, or of a little acid on cane-sugar. The same change occurs in many ripening fruits, in consequence of the presence of a peculiar albuminous ferment. Inverted sugar is not crystallizable, is soluble in dilute alcohol, and produces *left handed* rotation; hence its name. By chemical means, it is convertible into grape-sugar, a change which sometimes occurs spontaneously, as is seen in the gradual crystallization of the sugar in dried fruits.

Grape-sugar, constituting the hard granular sweet masses occurring in old dried fruits, such as raisins, figs, etc., has already been described in the article GLUCOSE, or GLUCOSE, under which names it is commonly known to chemists. It is also known as *starch-sugar*, because it is readily obtained by the action of a dilute acid on a hot solution of starch, and is identical with the sugar occurring in the urine in diabetes.

Milk-sugar, known also as *lactine* and *lactose*, $C_{12}H_{22}O_{11}$, or, according to some chemists, $C_{12}H_{22}O_{11} + H_2O$, is a purely animal product. It exists in considerable quantity in the milk, especially of the herbivorous animals, and is one of the most important and essential ingredients in that secretion. It may be obtained on a large scale by separating the curd from the milk, and evaporating the whey till it is ready to crystallize; when, on the introduction of small pieces of wood, the crystals of sugar are deposited on them. These crystals are four-sided prisms of a milk-white color, and so hard that they crunch between the teeth. This variety of sugar is only moderately sweet (*vide supra*), requires about six times its weight of cold water for its solution, but dissolves readily in boiling water, while it is insoluble in alcohol or ether. If it be gradually heated to 284° F. (140° C.), two equivalents of water are expelled, whereas, if it be suddenly heated to about 400° F. (204.5° C.), all five equivalents are given off. When pure, milk-sugar is insusceptible of fermentation; but when boiled with dilute acids, it is converted into a directly fermentable sugar, in many respects very similar to grape-sugar, and to which some chemists have given the name of *lactose*, a term commonly applied to milk-sugar itself. On treating a moderately diluted acid solution of milk-sugar with yeast, this variety is first formed, and then yields carbonic acid and alcohol; if, however, decomposing matters, as, for example, casein in the act of disintegration, are present, it undergoes lactic and butyric fermentation; and hence we understand how milk after exposure for a time to the air becomes sour. The intoxicating character of the drink prepared by the Kalmucks and Tartars from sour mares' milk, is due to this indirected vinous fermentation of sugar of milk. Regarding the uses of this variety of sugar, it may be observed that it is probably the most important of the constituents of whey (which is milk deprived of the whole of its casein except a mere trace held in solution), and hence that it is the active ingredient in the *whey-cure*, which is so popular in Switzerland. (The whey in these cases is usually obtained from goats' milk.) It is also the chief constituent of the globules used in homeopathy.

The second group of sugars, namely, those which are incapable either directly or indirectly of undergoing fermentation, are of less practical importance than cane sugar, grape-sugar, or milk-sugar.

Inosin, or *inosite* (derived from the Greek *is*, gen. *inos*, muscle), is represented by the

formula $C_6H_{12}O_6 + 2H_2O$. It occurs as a normal constituent in the juice of the heart, and of the involuntary or unstriated muscles, and has also been found in the tissues of the lungs, spleen, liver, kidneys, and brain, and in the urine in Bright's disease and diabetes. It has been recently shown that it is identical with the substance previously known as *phaseo-mannite*, which is readily obtained from the unripe seeds of the common kidney-bean (*phaseolus vulgaris*). It forms colorless efflorescent prisms, which lose two equivalents of water at about $212^\circ F.$ ($100^\circ C.$). When mixed with decaying cheese and chalk, it becomes gradually converted into lactic and butyric acids. *Seyllite* is a saccharine matter closely resembling inosite, and occurring in various organs of several plagiostomous fishes, and especially in the kidneys of the rays and skate. It differs, however, from inosite in its crystalline form, and in its containing no water of crystallization. Its composition is unknown. *Sorbin*, or *sorbite*, $C_6H_{12}O_6$, derives its name from its occurring in the juice of the berries of *sorbus aucuparia*, the service tree, and may be obtained in colorless transparent rhombic octahedra. It reduces oxide of copper to the suboxide (Trommer's test), and is of a sweetish taste.

Closely allied to the sugars, but differing from them in their chemical composition (inasmuch as they do not contain hydrogen and oxygen in the proportions to form water), are *mannite*, $C_6H_{14}O_6$, obtained from *manna*, the inspissated juice of the *fraxinus ornus*, but also occurring in celery, onions, asparagus shoots, *laminaria saccharata* and other sea-weeds, certain fungi, the juice which exudes from apple and pear trees; *dulcite*, $C_6H_{14}O_6$, the product of an unknown Madagascar tree; *quercite*, $C_6H_{12}O_6$, obtained from acorns; and *pinite*, $C_6H_{12}O_6$, from *pinus lambertiana*, a tree growing in Australia and California. All these bodies are crystalline, and sweet to the taste.

Although chemists have hitherto looked upon the sugars as organic compounds, without any recognizable radical, and from their composition have termed them *carbohydrates*, "the researches of Berthelot render it probable that the sugars as well as mannite, and the bodies allied to it, are polyatomic alcohols, like glycerine, for he has found that they possess the power of entering into combination with various acids, with elimination of water, in some cases yielding colligated acids analogous to the tannic, and in others furnishing neutral bodies, closely allied to the fats." Miller's *Organic Chemistry*, 2d ed. p. 72.

Among the various chemical purposes to which the phenomenon of circular polarization may be applied, we may especially mention its use in determining the quantity of any kind of sugar in solution. While some sugars give a right-handed rotation, others give a left-handed rotation, and each sugar exerts a definite amount of rotatory power. The following are the rotatory powers of the chief varieties of sugar, equal weights of each being dissolved in an equal bulk of water, and the temperature being $59^\circ F.$ ($15^\circ C.$):

| | | | |
|----------------|----------------------------|-------|--------------|
| Cane-sugar | $C_{12}H_{22}O_{11}$ | right | 73.2° |
| Milk-sugar | $C_{12}H_{22}O_{11}$ | " | 58.3° |
| Melezitoze | $C_{12}H_{22}O_{11}$ | " | 94.1° |
| Melitose | $C_{12}H_{22}O_{11}$ | " | 102° |
| Trehalose | $C_{12}H_{22}O_{11}$ | " | 220° |
| Grape-sugar | $C_6H_{12}O_6$ | " | 57.4° |
| Inverted sugar | $C_6H_{12}O_6$ | left | 26.7° |
| Sorbin | $C_6H_{12}O_6$ | " | 46.9° |

For details regarding the apparatus to be employed, and the method of using it, we may refer to Miller's *Chemical Physics*, 3d ed. p. 204; and to a memoir by Clerget in the *Ann. de Chimie*, iii., xxvi. 175. This method has been applied to determine the amount of sugar in diabetic urine, to ascertain the quantity of sugar which remains in the unfermented state in wines, and to other similar purposes. As, however, the process is one of extreme delicacy, this method must be used with great caution.

Manufacture.—The manufacture of sugar from the sugar-cane and other sources is now one of the largest branches of human industry, but this great development is of comparatively recent date; and although there are evidences of its very high antiquity in India and China, sugar appears only to have been vaguely known to the Greeks and Romans. It is mentioned by Theophrastus as "honey in reeds;" and Lucan has the following line, which indicates a knowledge of its existence, but merely as a curious fact:

Quique bibunt tenera dulces ab arundine succos.

Its introduction to Europe appears to have been one of the results of the Crusades. The sugar-cane was grown in Cyprus about the middle of the 12th c.; it was from thence, at a later time, transplanted to Madeira, and at the commencement of the 16th c., was carried from the latter island to the West Indies. Originally, in all probability, only the sweet recent juice was known; for apparently the art of boiling it down, and forming it into raw sugar, was an invention of the 15th c.; and it was not until the middle of the following century that a Venetian discovered the art of refining sugar, which soon became established in Germany. The first refinery of which any notice exists was one in Dresden, as early as 1597; but long previous to this the subject had attracted so much attention as to be discussed in learned treatises, one of which in particular, the *Saccharologia* of Sala, in the beginning of the 16th c., shows that the clarification of the syrup by defecation was then a matter of some importance. Still, the manufacture of sugar in the

countries to which it had been introduced made but slow progress, for its use was limited by its dearness to the wealthy. The material has now, however, become one of the commonest necessities of life, and has largely conduced to the health of nations. Until 1747, sugar was supposed to be the product of the sugar-cane only, but in that year, Marggraf, a German chemist, demonstrated that it was a natural product of other vegetables, and especially of the beet-root; and half a century later, its manufacture from that source was first commenced in Silesia. A large portion of the sugar consumed on the continent is now obtained from this source. See BEET-ROOT SUGAR.

Since we have become better acquainted with the sources of sugar supplies, we have learned that a large portion of the raw sugar of the East Indies received in British ports as cane-sugar is in reality made from the juice of several palms, especially that of *arenga saccharifera*, and the wild date, *phoenix sylvestris*. The juice is obtained from these plants by cutting off the male spadix when young, and from the cut portion there is for four or five months a continual flow. The liquid is at first clear, and is immediately boiled down to a thick syrup, which granulates on cooling, and constitutes, if not otherwise purified, the coarse brown sugar called jaggery, which is extensively consumed in India. More carefully prepared, it is sent to Europe with sugar made in the cane-plantations, and is only distinguished from it by well-skilled persons. If the juice is not immediately boiled, it becomes turbid, and passing into the vinous fermentation, forms the intoxicating drink called toddy.

In Canada and in the United States very much sugar is made by boiling the juice or sap of the sugar maple-tree (*acer saccharinum*). The *sorghum saccharatum*, or sugar-grass (see DURRA), and the stalks of ordinary maize or Indian corn (*zea*) yield sugar, which has lately been made so as fairly to rival the best crystallized cane-sugar (see under SUGAR-CANE).

Beet-root sugar is manufactured from the fresh-dug roots, chiefly of the varieties we call mangold-wurzel. The process (which, however, is constantly undergoing modifications) is briefly described in the article BEET-ROOT SUGAR. Beet-root yields from 7 to 8 per cent of sugar, of which only 3 to 4 per cent are of the best quality, called *melis*, 2 to 3 per cent of the second quality, called *farin*, and the remainder molasses.

The manufacture of starch-sugar is described in the article GLUCOSE.

From the beginning of the 16th c., when the sugar-cane of India was introduced to the West Indies, sugar has been one of the most important products of those islands. Careful cultivation has produced many varieties of this useful plant, some of which are better adapted than others for particular localities. The original variety introduced into the West Indies is still cultivated under the name of the *Creole cane*; but the favorite variety is the *Otaheite cane*, which is the most luxuriant grower, and gives the largest yield of juice. It is the variety chiefly cultivated in Brazil, Demerara, and Venezuela, as well as the West Indies. In many parts of the east, another admirable variety is the *Batavian or striped cane*; it was originally raised in Java, and is the favorite with rum-distillers.

The extraction of juice from the sugar-cane is effected by simple pressure. In its native country, India, there are still in use in some districts machines of the rudest construction, which are probably the same which were used a thousand years since. The Chinapatam sugar-mill consists of a mortar made by cutting down some hard-wood tree to within 2 or 3 ft. of the ground, and hollowing the top of the portion left standing in the ground into the form of a mortar. A small hole is then bored obliquely through from the bottom of the cavity to the outside, and a pipe conveys the juice into a jar. A cylindrical piece of wood, sharpened at each end, acts as a pestle, and is kept in its place with sufficient pressure by a lever and ropes. Two men are required: one has a basket supplied with small lengths of freshly-cut cane, which he places, 2 or 3 at a time, in the mortar, and, when necessary, removes the crushed ones; the other man sits on the other end of the train, balancing it, and at the same time drives oxen which are attached to the end of the beam, and keeps the movable parts of the mill constantly turning round. Notwithstanding the rudeness of this contrivance, very large quantities of sugar are made by it in India. A much better one, however, is the Chica Ballapura engine, which consists of two upright rollers, the heads of which are formed into double spiral screws, which work in one another, so that when an ox is yoked to the long curved lever and goes round, one of the upright rollers, being connected with the lever, is made to revolve, and its screw carries the other one round, but in an opposite direction. The pieces of cane are fed in by hand between the rollers, and as the juice is squeezed out, it flows down into a small hollow below the frame made to receive it, whence a small trough carries it to an earthen pot. The frame of this mill is securely fixed with stakes driven deep into the ground. In all probability, this very ancient machine has been the origin of all the most modern ones, for they all consist of rollers placed either vertically or horizontally, between which the canes are made to pass.

The mills now in general use for squeezing the juice out of the sugar-canes are very powerful machines. Some idea of the strength of those mills will be formed from the fact, that one of the rollers weighs upward of 5 tons. The axles are 12 in. in diameter, and notwithstanding that they are made of the best wrought iron, they are not secure against breakage. The manufacture of sugar has probably been carried to greater perfection in the islands of Java, Mauritius, and Cuba, than in any other parts

of the world. In Java especially, in consequence of the great extent of the plantations, the planters have been able to erect very complete establishments for the manufacture of sugar.

The following very condensed account of the process of making sugar in Java will give some idea of the operation.

The canes, freed from all loose leaves, are passed through between the rollers under the greatest possible pressure that can be brought to bear upon them. The rollers revolve only from two to four times per minute. From 100 lbs. of canes, 65 to 75 lbs. of cane-juice will be expressed. This juice, which is of a sweetish taste, and of the color of dirty water, passes direct from the mill to a small reservoir, where it usually receives a small dose of quicklime, and without delay runs off to large iron or copper vessels, heated either by a fire underneath or by steam-pipes in the liquid. As the temperature of the juice rises, a thick scum comes to the top, which is either removed by skimming, or the warm juice is drawn off from below the scum. The concentration of the juice is partly effected in a series of large open hemispherical iron pans about six to eight ft. diameter, of which five or six are placed in a row, with a large fire under the one at the end. This one fire, which runs along under the whole row of pans, is found sufficient to make two or three of them nearest the fire boil violently, and in addition, it warms the juice in the pans furthest from the fire. As the juice first enters the pans furthest from the fire, it gets gradually heated, and the vegetable impurities rise in scum to the top, and are carefully removed. As the juice is ladled from one pan to the next, it boils with greater and greater vigor as it approaches nearer the fire, until in the pan immediately over the fire it seethes and foams with excessive violence; and this seems to be essential to the successful making of sugar. It is known that the presence of all those impurities which constitute the scum interferes with the crystallizing of the sugar; and the rapid ascent of bubbles of steam through the liquid in the pans carries all impurities dispersed through the body of the liquid to the top, where they can be removed with facility. It is well known that great heat is very destructive to cane-juice; that is to say, it turns much of the crystallizable sugar into treacle or uncrystallizable sugar, but the gain arising from getting rid of much of the impurity in the cane-juice more than compensates for the destruction of part of the sugar. After the concentration has been carried to a given point, and all the scum has been got rid of, the application of a high heat, which would act with an increasingly destructive effect as the condensation became greater, is suspended, and the liquor, now of the color of turbid port wine, and of the consistency of oil, is drawn into the vacuum-pan, where the concentration is completed at the lowest possible temperature, generally about 150° Fahr. The vacuum-pan is in universal use in all European sugar-refineries, and in all well-provided sugar-plantations. It is generally made of copper, of a spherical form, and from six to nine feet diameter. The bottom is double, leaving a space of an inch or two for the admission of steam between the two bottoms, and there is generally a long coiled copper pipe of three or four inches diameter above the inner bottom, so as to still further increase the amount of heating surface. This apparatus is made perfectly air and steam tight. Leading from its upper dome, there is a large pipe, communicating with a condenser into which a rush of cold water is continually passing, so as to condense all the steam or vapor that arises from the liquid boiling in the vacuum-pan. The water which is constantly rushing into the condenser is as steadily withdrawn again by pump. There is thus a constant vacuum in the pan, and, consequently, the liquid in it will boil at a much lower temperature than it would in an open pan or boiler. There is an extraordinary advantage in being able to effect the latter stages of concentration at a low temperature, for it is when the liquid becomes thick that the destructive results of a high temperature become most excessive.

As the concentration of the liquid in the vacuum-pan proceeds, crystals of sugar begin to form, and the skill of the sugar-boiler is shown by the uniformity of the crystals he produces. The boiling is commenced by filling in only about a third or fourth of the quantity the vacuum-pan will hold, and gradually adding more liquid as the crystals increase in size. The sugar-boiler is able to watch the changes going on in the vacuum-pan by means of small samples he withdraws from it by means of a suitable apparatus. The sugar-boiler holds those drops of thick fluid on his finger and thumb, between his eye and a strong light, and is thus able to detect those minute changes in its condition which show that it is time to add an additional quantity. By the time the vacuum pan is full, the contents have thickened, by the formation of crystals of sugar, into a mass of the consistency of thick gruel; it is then allowed to descend into a vessel called the heater, where it is simply kept warm until it can be run out into the "forms," which, in the sugar-growing colonies, are generally conical earthen pots, holding from one to two cwt. of sugar. It is allowed to cool and complete its crystallization before the plugs, which close the bottom of the pots, are withdrawn. When this is done, from one-fourth to one-third of the contents of the forms, which has remained in a fluid state, runs off into gutters leading to large tanks, from which it is again pumped up into the vacuum-pan, and reboiled, yielding a second quality of sugar. This reboiling of the drainings is repeated, with a continually decreasing result, both as to quantity and quality of the solid sugar obtained, and it is rarely carried beyond the fourth boiling. If the planter wishes to obtain Muscovada or unclayed sugar, the process is now complete, and the sugar is turned out of the forms, and packed for shipment. In some cases, the sugar is

run direct from the vacuum-pan into casks or hogsheads, which replace the forms, holes being bored in the bottoms of the casks, to admit of the uncrystallized portion of the sugar draining out.

If *clayed* sugar is to be made, the forms are allowed to stand for a few days until all the treacle has drained out; and a quantity of thin mud, about the consistency of good thick cream, is then poured over the sugar to the depth of one or two inches. The water contained in this thin mud slowly steals down through the sugar, and mixing with the coatings of treacle still adhering to the outsides of the crystals of sugar, renders them less viscid, and facilitates their descent to the bottom of the form. The mud remains, at the end of a few days, in the form of a dry hard cake on the top of the sugar, and none mixes with the sugar.

The process of claying sugar is simply washing off a coating of black or yellow treacle from a crystal of sugar, which is always white. This operation is possible without dissolving the crystal of sugar, simply because the treacle has a greater affinity for water than the crystallized sugar has. Anything that would yield a very slow and steady supply of water to the sugar, would do as well as mud or clay. There is always some loss of crystallized sugar in the process of claying, and attempts have been made to use strong alcohol for washing off the coatings of treacle from the crystals; but although alcohol dissolves treacle very freely, and scarcely acts on the crystals at all, still it has not been found to answer commercially. Besides the cost of the process, there is a difficulty in getting rid of the smell of alcohol in the sugar.

The centrifugal machine of Messrs. Manlove, Alliott & Co. has been very extensively used for getting rid of the treacle. Its action depends on precisely the same principle as that called into play when a sailor twirls a mop to expel the water from it. The centrifugal machine is simply a drum of 3 or 4 feet diameter, and 12 to 18 inches high, revolving at a great velocity on a vertical axis. The sugar, either direct from the vacuum-pan or after it has been allowed to cool, is put, still mixed with the treacle, into the machine. As soon as the drum acquires a high velocity its contents are forced by the centrifugal action against the drum, the cylindrical portion of which is made like a sieve, and admits of the escape of the treacle, but retains the crystals of sugar. Some idea of the efficiency of those machines may be formed when it is stated, that in a machine of 3 ft. diameter, revolving at the usual speed of 1000 revolutions per minute, the tendency of the treacle to escape will be 514 times its own weight; that is to say, the treacle will have 514 times more force to fly off than it has to drop off the crystal by the mere force of gravity.

Sugar-refining was unknown to the ancients, and even the refining previously referred to as having been established in Germany in the 16th c. consisted merely in clarifying the syrup, and producing a sort of sugar-candy; but one improvement followed another, until the process may now be considered as almost perfect. The chief difficulties attending the operation arise from the circumstance that the material to be operated upon is ever varying in quality. Not only is there a difference between the produce of two different plantations, but even the manufacture of the same plantation shows differences of quality; these differences arising chiefly from the presence of foreign substances, which seriously interfere with the operations of the refiner. The attempts made to test the exact quality of solutions of raw sugar by means of polarized light (see above) have hitherto been attended with little success in practice. Sugar-refining, as practiced in Britain, has three distinct objects—(1) the production of loaves of thoroughly refined sugar; (2) crushed sugar; and (3) white sugar in separate crystals. The last is of comparatively recent introduction. In some existing sugar-refineries, old fashions still prevail; but our description must be confined to the most recent methods.

Sugar refining is carried on in the United States on a great scale, New York, Brooklyn, and New Orleans being the principal seats of the trade. There is comparatively little raw sugar used in Great Britain. Nearly all the yellow and dark-colored sugar sold in the shops has passed through the hands of the refiners, and is simply inferior sugar, made out of the syrup which drains from the white loaf-sugar.

Sugar-refineries are built eight or nine stories high, and the raw sugar is first hoisted to the upper story, where it is dissolved in large tanks of hot water, care being taken to use as little water as possible for the purpose. A quantity of bullock's blood is stirred into the solution of sugar, and the heat being gradually raised, the albumen of the blood coagulates, and rises to the surface in the form of a thick light scum, bringing with it nearly all the mechanical impurities floating in the fluid. The liquor, still hot, is then passed into bag-filters. Those filters are made of a very closely woven cotton cloth, capable of retaining the minutest mechanical impurity. In order to facilitate the passage of the liquor through the bags, they are suspended in a kind of iron closet, and surrounded by an atmosphere of steam to keep the liquor hot. From the bag-filters the liquor, now freed from all mechanical impurities, but of a dark color, flows into a lofty cylindrical iron filter, of about 5 or 6 ft. diameter, and 20 or 30 ft. high, filled with animal charcoal, that is, charcoal made of bones. This charcoal is reduced to coarse powder; and the dark offensive liquor is allowed to percolate very slowly through the mass. The result is, that it flows out at the bottom a perfectly transparent and pure solution of sugar. The charcoal can only be used for a few days at a time, because it gradually loses its purifying power; when the liquor begins to flow through it without

being purified, it is taken out of the filter, and reboiled, which completely revives its powers.

The liquor as it flows from the charcoal filter is a mixture of pure sugar and pure water, and perfectly transparent. The application of heat is the only mode of expelling the water, and this unfortunately blackens the sugar again. In order to get rid of the water with as little heat as possible, the colorless liquor is boiled in the vacuum-pan as in the early process of the manufacture. The liquor boils in vacuo at about 150° F., and even this moderate heat has the effect of turning it quite brown. When it has been sufficiently concentrated by boiling in the vacuum-pan, which takes from 1½ to 2½ hours, it is run into the sugar-loaf forms; which, after cooling, are carried to a room kept warm by means of steam-pipes. This warmth facilitates the flow of the treacle or syrup out at the aperture at the bottom of the form. To get rid of the coating of colored treacle which still hangs about the crystals of sugar, a small quantity of a saturated solution of pure white sugar is poured on the top of the form. This strong liquor is unable to dissolve any more sugar, but being more fluid than the sticky coatings of treacle or syrup adhering to the crystals, it mixes with the coatings, and makes them fluid enough to flow down to the bottom of the form, leaving the crystals clear of syrup or treacle, and consequently free of all color. This process of washing off the coloring matter from the crystals of sugar is the same in principle as the "claying" used in the production of sugar. The loaves of sugar, after standing some time, to admit of all the liquor draining off, are wrapped in paper, and dried in stoves heated by steam. The liquor draining from the forms is reboiled in the vacuum-pan, and forms loaves of an inferior quality; and the liquor draining from the inferior loaves is again boiled into the yellow sugars known among sugar-refiners as bastards.

Crushed or crashed sugar is simply inferior loaves crushed while still soft and moist, and packed in hogsheads, instead of being left in the loaf form.

The syrup which drains from refined sugar is reboiled, and constitutes the *golden syrup* of the shops.

Crystal Sugar.—In making the sugar crystals, all the processes are carried on as in refining, until the syrup is clarified. Then it is boiled or concentrated in a vacuum-pan of larger size than ordinary, and the concentration is carried on until minute crystals appear. Fresh syrup is then added from time to time, great care and experience being required to insure a regular feeding of the first-formed crystals, and prevent the formation of a second crop. When the crystals are large enough, the contents of the pan are transferred to the centrifugal machines, which quickly separate the crystals in a perfectly dry state from the uncrystallizable syrup. The crystals are of a square tabular form, with a deep groove across in one direction, dividing the crystal into equal parts. This kind of sugar is much liked for coffee, etc., but the crystals dissolve with difficulty.

The loss of such a large portion of the sugar in the processes of manufacturing has led to many inventions for the extraction of the juice, and for its more economical conversion into sugar. The cane mills now generally used are provided with three rolls, and with them the yield is not more than 70 to 80 per cent of juice, the lower limit being the more common. Seeing that with the most powerful rolls much juice is still left, other machines have been employed. Among these are the defibrators. In one of these the cane is reduced to a pulp; it then passes into a press, which squeezes out the juice. In another process the cane is put through a machine that breaks all the joints and outer covering; in this condition it is passed through an ordinary mill. The previous cracking of the joints allows a more constant and uniform pressure in the mill. Both of these methods give a better yield than the ordinary single milling. Duchassaing has invented a machine in which the cane first passes through one set of rollers; it is then carried along on an endless cloth to a second mill; between the first and second are a number of jets, which discharge boiling water upon the cane; thoroughly wetted, it goes through the second mill. With this machine the yield of sugar has been increased from 9.4 per cent to 11.04 per cent. The principle of osmotic action has been applied to extraction of the sugar. In the cane the sugar is held in solution in cells, inclosed by vegetable membrane. This membrane acts as the *septum*, and when the sliced cane is placed in water, the sugary solution in the cell passes out, until the density of the two liquids becomes the same. The water containing the sugar is then drawn off, and a new supply added, when the sugar again passes out; this process is kept up till all the sugar is extracted. If for every gallon of juice we use a gallon of water in the first step, one half the sugar would be extracted. To carry on the process economically, the first water should be applied to the second cane, and so on, till at last it should be as rich in sugar as the cane juice. The juice obtained in this way is free from all the crushed and broken cane. The cane is sliced diagonally into thin chips, so as to expose as large a surface as possible to the water. The inner part of the cane contains a richer juice than the outer, and less mineral matter than the knotty portions; the juice also varies in the different varieties and with different soils. According to Dr. Icery, of Mauritius, it contains water, 81, sugar, 18.36, mineral salts, .29, and organic substances, .35. The presence of a certain amount of uncrystallizable sugar is a source of great loss, as it not only does not crystallize itself, but prevents an equal amount of the sucrose from crystallizing. Fermentation converts sucrose into invert sugar. This takes place in the cane under the influence of air and a moderately high temperature. After the juice has been expressed the acid in it sets up fermentation. In

some climates sound cane can be kept for three or four months without injuring the sugar, but where it is very warm the juice should be pressed out as soon as the cane is cut. The amount of sugar can be closely estimated by the density of the juice, and the amount of mineral matter contained varies with the soil. The organic substances may be divided into three classes—albuminous, nitrogenous, and granular; the first class being one of the main causes of fermentation. When the juice is raised to the boiling point, the albumen coagulates and floats to the surface, carrying up with it the granular matter. The acidity of the juice is partly due to the granular and albuminous matter, and the effect of the nitrogenous is to prevent crystallization. For purifying the juice, heat and chemical and mechanical agents are employed. Heat, by killing the germs producing the acetous fermentation, checks it; it also drives off some of the acids, and under its influence the chemical changes go on much more vigorously. Steam has been found to be the most convenient method of applying heat, as it can be easily regulated. The acid in the juice is neutralized by lime, and the determination of the right amount requires careful experiment, different juices needing different quantities. It has been thought that lime might be replaced, with advantage, by the more powerful alkalis; but they have not come into use. The juice is run through filters, to remove those impurities that have not been taken out by heat and the chemicals. It is during the process of concentration that much of the sucrose is converted into uncrystallizable sugar, and it is at this stage that the temperature has to be carefully regulated. Fryer has devised a method of concreting the syrup at this stage without letting it go through the process of crystallization: the syrup flows down a shallow inclined pan, heated by a flue coiled beneath; at the lower end of the pan it falls into a reservoir, from which it passes into a revolving cylinder, heated by a current of hot air drawn through by a fan; when drawn out of this cylinder it cools into a hard mass, that can be packed in bags, ready for shipment. The inclined pan has a system of ridges, forcing the syrup to take a zigzag course, and bringing it into contact with much greater heating surface. The method of concentration of the syrup, by forcing a current of cold air through it, has been successfully employed, but has not come into general use. Considering the loss of crystallizable sugar that takes place during the concentration, and the great improvements that have been made in the cold-air machines, it seems that their employment would add largely to the yield. In La., one acre of cane weighs from 40,000 to 60,000 lbs. It is estimated that 1000 tons of cane take up from the soil about five tons of mineral matter. The central system, in which the planter sends his cane to a large factory to be made into sugar, instead of doing it himself, thereby saving the expense of the plant, is becoming common.

Sulphuric acid converts cane sugar into a black mass; it can also be employed to distinguish glucose from cane sugar. Since the manufacture of glucose has been so largely increased, its employment, in the adulteration of sugar, has become very common; it does not make the sugar unwholesome, but decreases its sweetening properties. Glucose rotates the polarized ray much more than cane sugar, so that the polariscope usually serves to detect the mixture. The salts contained in sugar prevent its crystallization. Dubrunfaut has employed the principle of osmotic action to remove them from molasses, thereby rendering a portion of it crystallizable. The value of the crude sugar for refining is determined by the amount of crystallizable sugar it contains, and its color indicates the amount of charcoal it will require. In the U. S., the manufacture of sugar from sorghum (q. v.) is attracting much attention; it is estimated that some varieties of sorghum contain as large an amount of sugar as the average Louisiana cane, and that it can be as easily extracted. Some of the sugar planters are experimenting with it, with a view to its introduction.

The total amount of sugar consumed in the United States in the year 1895 was 1,949,744 tons, of which 325,621 tons was produced in the United States. This consumption amounts to 62.6 pounds per capita. The sugar consumed in 1895 consisted of the following grades: refined product of imported sugar, 1,572,438 tons; manufactured from imported molasses, 15,000 tons; of cane, 324,506 tons; of maple, 7,500 tons; of beet, 30,000 tons; of sorghum and others, 300 tons. Leading refiners say that little or no sugar is manufactured from domestic molasses; also that in refining there is only about 2% loss of original. Messrs Willett and Gray, New York, state that of the sugar consumed in 1895 only about 182,964 tons were unrefined. The duty collected on sugar amounted in 1895 to \$15,354,290, and the amount of sugar bounties paid to sugar producers during the fiscal year 1892 was \$7,342,078; 1893, \$9,375,131; 1894, \$12,100,209.

SUGAR-CANE, *Saccharum*, a genus of grasses, natives of tropical and sub-tropical countries. The common sugar-cane (*S. officinarum*) is originally a native of the East Indies, was brought to the s. of Europe by the crusaders, and in the 15th and 16th c. found its way into all the European colonies within the tropics. In Europe the cultivation of the sugar-cane has always been very limited, and is scarcely practiced except in Sicily and Andalusia. In China it extends to 30° n. lat., and in North America to 33°; in the southern hemisphere only to 22° s. lat. The plant is a perennial with a creeping root, sending up a number of culms or stems, generally 8 to 12 ft. high, which have many joints, are of various colors, and about 1 to 2 in. thick. They are filled for about two-thirds of their length with a loose, sweet, juicy pith. The leaves are ribbon-shaped, and 4 to 5 ft. long, with a strong whitish middle nerve. The flowers are in great diffuse pyramidal panicles of a yard in length. The violet-colored sugar-cane (*S. violaceum*) is particularly esteemed, and much cultivated in the West Indies.—The Chinese sugar-cane

(*S. sinense*), cultivated in China, has the stem in great part covered with the sheaths of the leaves. Cultivation has produced many varieties of these species; if, indeed they are originally distinct species, and not themselves mere varieties.—The species of *saccharum* are numerous; they contain much silica in the rind, and some of them are much employed in India for thatching and for making mats, as well as for screens and light fences. The Bengalese make their pens of the hollow stems of *S. semidecumbens* and *S. fuscum*. See *illus.*, GRAIN, ETC., vol. VI., p. 874, fig. 9.

The sugar-cane is usually propagated by cuttings. For this purpose the top joints are used. The cuttings are planted in rows 3 or 4 ft. apart, and at intervals of about 2 ft. in the rows. The largest varieties, in rich moist soils, attain a height of 20 ft.; but in dry poor soils, the height is sometimes scarcely more than 6 feet. The plant *tillers*, like wheat, but not to the same degree. The cane-ground is kept clean by hand-hoeing, or by the plow. Hand-hoeing was formerly universal in the West Indies, but the plow is now very generally used where the nature of the ground permits. The best varieties are ready for cutting in about ten months from the time of planting, but other varieties require a longer period of growth, from 12 to 20 months. When the canes are fully ripe they are cut a little above the ground, and tied in bundles to be conveyed to the mill. Fresh canes called *rattoons* spring from the root, so that the plantation does not require to be renewed for several years; but the canes of the first crop are the largest, and a gradual decrease of size takes place. The ordinary practice on sugar estates is to renew a part of the plantation every year.

The name CHINESE SUGAR-CANE is sometimes given to the SHALOO or SUGAR-GRASS (*sorghum saccharatum*), already noticed in the article DURRA. A still more important sugar-yielding grass is the ordinary maize or Indian corn. The sorghum became known in America in 1857, and has latterly been extensively cultivated for producing syrup. It has long been known that sugar could also be obtained from the stalks of maize; but neither sorghum sugar nor maize sugar could till lately be made so as to compete commercially with the produce of the sugar-cane. Recently, however, an American gentleman—Mr. Stewart, of Murraysville, in Pennsylvania—has discovered a method of obtaining from both sorghum and maize crystallized sugar equal to the best kinds known. The processes are somewhat simpler than those in use for the sugar cane, and are more economical than those employed in making beet-sugar.

SUGAR-OF-LEAD, the common name for acetate of lead. See LEAD.

SUGDEN, EDWARD BURTENSHAW, 1781–1875; b. at London; was admitted to the bar in 1807; became king's counsel, 1822; solicitor-general and was knighted, 1829; lord chancellor of Ireland, 1835 and 1841–46; lord high chancellor of Great Britain, 1852. He is the author of *Law of Vendors and Purchasers* (1805), *Powers* (1808), *Law of Property as administered by the House of Lords* (1849), and other works of legal importance.

SUGGESTIO FALSI (Lat., “the suggestion of falsehood”) means giving a false impression without having made a decidedly false statement. This expression is applied to the sophistry practiced in oratory. See SUPPRESSIO VERI.

SUHL, a t. of Prussia, province of Saxony, and government of Erfurt, is situated on a small stream, called the Lauter, in a romantic valley on the s.w. side of the Thuringian forest, 30 m. s.s.w. of Erfurt. Pop. '95, 11,887.

SUHM, PETER FREDERIK, a Danish historian, was b. in Copenhagen, Oct. 18, 1728, of an ancient and noble family, and was sent to the university of Copenhagen, where he graduated in law in 1748. A few years later he went to Norway for the sake of prosecuting his studies in philology and history, in conjunction with the learned historian Schöning, and did not return till 1765 to Copenhagen, where he continued to reside till his death in 1898. Among his numerous works on the early mythical and political history of Denmark we may instance the following: *Forsoeg til Forbedringer i den gamle danske og norske Historie* (1757); *Om de nordiske Folks ældste Oprindelse* (1770); *Om Odin og den hedenske Gudelære* (1771); *Kritisk Historie af Danmark i den hedenske Tid*, (4 vols., 1774–81); *Danmarks Historie* (1782–1828). Besides numerous other historical essays, moral treatises, poetic compositions, contributions to the philosophical and literary periodicals of Germany, France, and Denmark, etc., he edited *Scriptores Rerum Danicarum Mediæ ævi*, from vol. iv. to vol. vii. inclusive (Hafniæ, 1776–92), and took upon himself the cost and supervision of the publication of many remains of old northern literature. Suhm was an indefatigable collector of rare and curious books; and in 1796, in return for a pension from the government, he made over to the royal library of Copenhagen his valuable library of 100,000 volumes, to which he had previously allowed the public access. He had copies made of the more valuable MSS. in the collection; besides which he founded scholarships and afforded direct pecuniary assistance to many poor students and learned men. He died in 1798. Suhm's collective writings were brought out by S. Poulsen, in 16 vols., between 1788–99.

SUICIDE (Lat. self-murder) is a heinous crime, by the law of the United Kingdom, though it was treated as venial by the Roman law, and was the subject of panegyric by Stoic philosophers. The law of England treats it as a felony, and hence there may be accessories to it, so that if A persuade B to kill himself, and B does so, A is guilty of murder. Suicide, or *felo de se* (q.v.), not only includes one who deliberately kills himself, but also one who in maliciously attempting to kill another is himself killed. If A, however, requests B to kill him, and B does so, A is not a *felo de se*, though B is a murderer. If A and B mutually agree to commit suicide together, and in the attempt one

only dies, the other is guilty of murder. When it is said that a man was a suicide, this implies that he was in his senses, for otherwise he committed no crime; hence an insane person, unless when in a lucid interval, cannot commit the crime. The punishment inflicted on a suicide consisted, formerly, in an ignominious burial in the highway, with a stake driven through the body, and without Christian rites, also the legal consequence was forfeiture of the goods and chattels to the crown. The only consequences now are forfeiture of goods. An act of 1824 permitted burial in churchyards without rites, between 9 and 12 P.M.; the interments (*felo de se*) act of 1882 sanctioned burial at any hour, and with the usual rites. An attempt to commit suicide is not punishable like an attempt to murder a third party, nevertheless it is a misdemeanor. The consequences of suicide on the contract of life-assurance are generally guarded against by an express stipulation that, if the assured die by his own hand, the policy shall be void; and it has been held by the courts that the policy is forfeited even though the party destroyed himself in a fit of frenzy or delirium.

There are, no doubt, even in modern times, some who hold the theoretical opinion that suicide is permissible in certain circumstances, but in regard to those who have actually permitted or attempted the crime, there has almost always been detectable evidence of cerebral changes, or, at all events, of that irritation and excitement which initiate and accompany molecular disorganization of the nervous structure. In short, suicide, as a rule, is a symptom of some form of insanity, permanent or temporary, in which the emotions and passions are excited or perverted. Suicide is likewise a concomitant of certain bodily diseases; for example, of dilatation and fatty degeneration of the heart, of blood degeneration, of affections of the intestinal mucous membrane, of the uterus, and of the brain and nervous matter; and it may be regarded as a frequent sequence of the melancholic, the morose, and hypochondriacal temperament. It has appeared as an epidemic; it has been observed as a hereditary tendency in certain families, and as a tendency more frequently exhibited by males than females; more frequently by the educated and affluent than by the industrial and ignorant classes; most frequently in large cities, and as directly engendered by luxury, political agitation, gambling, intemperance, and demoralization. It would appear, however, that indulgence and asceticism, riches and extreme poverty, claim nearly an equal number of victims. It has been calculated that twice as many artisans commit suicide as laborers. Accurate observation has shown that from 20 to 35 is the most influential age in inducing the suicidal tendency, and the age appears to determine, to a certain degree, the modes of death selected as well as the proclivity. As might be expected, the nature of the delusion, the accessibility of the means, imitation, the profession or pursuit of the individual, novelty, and notoriety, all influence the choice of the instrument or means of death. The theomaniac dies by crucifixion; the great majority by ropes, rivers, wells, razors, arsenic; the medical man by aconite, chloroform. Even sex is characterized by peculiar preferences. Females seek voluntary death according to the following order of the means—hanging or strangulation, abstinence, precipitation, drowning, cutting, poison; males, again, according to this order—cutting, shooting, hanging, poison, drowning. Race, climate, country, and the distinguishing polity of different societies to a certain extent affect the proportion of suicides to the population. In European cities the number of suicides per 100,000 inhabitants is as follows: Paris, 42; Lyons, 29; St. Petersburg, 7; Moscow, 11; Berlin, 36; Vienna, 28; London, 23; Rome, 8; Milan, 6; Madrid, 3; Genoa, 31; Brussels, 15; Amsterdam, 14; Lisbon, 2; Christiania, 25; Stockholm, 27; Constantinople, 12; Geneva, 11; Dresden, 51. Madrid and Lisbon show the lowest, Dresden the highest figure.

The causes of suicide in European countries are reported as follows: Of 100 suicides: madness, delirium, 18 per cent.; alcoholism, 11; vice, crime, 19; different diseases, 2; moral sufferings, 6; family matters, 4; poverty, want, 4; loss of intellect, 14; consequence of crimes, 3; unknown reasons, 19.

The number of suicides in the United States, for the years, 1882–1887, was 8226. Insanity was the principal cause, shooting the favorite method. 5386 acts of suicide, were committed in the day and 2419 in the night.

SUIDÆ, a family of mammalia, of the order *Pachydermata*, having the feet generally four-toed, the hinder feet some times three-toed; the toes hoofed, the two front toes forming the principal part of the foot, the others smaller and scarcely touching the ground; the snout abruptly truncated, mobile, muscular, and sensitive, but not elongated into a proboscis; the tail short, or almost wanting; the incisor teeth variable in number, the lower ones all directed forward, the canines projecting, and bent upward; the stomach little divided. To this family belong hogs, wart-hogs, peccaries, etc.

SUIDAS, the name given to the compiler of a *Lexicon* some time during the Byzantine empire. When he lived, or who he was, or whether he was even called Suidas, no one can say, but it is customary to place him about the 10th or 11th century. The *Lexicon* bears unmistakable evidence of having gone through many hands; and though we can fix the date when several of the articles *must* have been written, it is impossible to ascertain whether they are the compositions of the first compiler or of a later editor. The work is a sort of cyclopedia, giving an explanation of words, and notices of persons, places, etc., in alphabetical order. It is utterly destitute of literary or critical merit, but is valuable in the eyes of scholars on account of its numerous extracts from ancient Greek writers, grammarians, scholiasts, and lexicographers, whose writings in many

cases have perished. The first edition appeared at Milan (1499): since then the best editions have been those of Küster (Camb. 3 vols. 1705), Gaisford (Oxf. 3 vols. 1834) Bernhardt (Halle, 2 vols. 1834), and J. Bekker (Berl. 1854).

SUI GENERIS (Lat., "of its own kind"). From its signification this term has come to denote that which is peculiar or unique.

SUI JURIS, in the Roman law, the condition of a person not subject to the *Patria Potestas* (q.v.). The paterfamilias was the only member of a family who was *sui juris*, all the rest being *alieni juris*, including sons, unmarried daughters, the wife, and the wives and children of the sons of the paterfamilias. A daughter, on her marriage, passed into the family of her husband, but a son did not become *sui juris* by marriage. A son or unmarried daughter became *sui juris* on the death of the paterfamilias. In his father's lifetime a son could only become *sui juris* by emancipation. The laws of the twelve tables declare that a son three times sold by his father should be freed from his power; and the ceremony of emancipation was of the nature of a fictitious sale gone through three times, in order to liberate the son from parental control. *Connubium* being the foundation of the *patria potestas*, a bastard was *sui juris*.

SUIR, a river of Ireland rising in the n. of the county of Tipperary, flows s. through that county by the towns of Thurles and Cahir; 10 m. s. of Cahir it bends eastward, forming the boundary of Tipperary and Waterford, and passing by Clonmel and Carrick. It then passes out of Tipperary, and meeting the Barrow at Passage, Waterford, falls into the sea in Waterford Haven, after a course of about 100 m. It is navigable by barges as far as Clonmel.

SUL, RIO GRANDE DO. See RIO GRANDE DO SUL.

SULEIMAN PASHA, abt. 1838-92. His original nationality was never discovered, though he was supposed to be a Pole who had embraced Mohammedanism. He became famous during the Russo-Turkish war, 1877-78. His attacks on Shipka Pass, though unsuccessful, won for him a reputation for great courage, and he was made commander-in-chief of the Turkish forces in Roumelia. Notwithstanding his victory at Elena and his battle near Metchka, 1877, he did not give satisfaction to the Turkish government, and was degraded from his post early in 1878.

SULFONAL. See HYPNOTICS.

SULIMAN' MOUNTAINS, a mountain range upward of 350 miles in length, running from n. to s., and forming the boundary between Afghanistan and the Punjab. In lat. about 33° 20', it throws off the lateral branch of the Salt Range (q.v.). The highest summit of the range is Tacht-i-Suliman (Solomon's throne), 11,000 ft. high, and covered with snow for three months of each year.

SULINA, one of the lower branches of the Danube (q.v.), flows through the middle region of the delta of the great river, and enters the sea at about the same distance from the Kilias mouth on the n. and St. George's mouth on the south. It is the smallest outlet of the Danube, and conveys only $\frac{2}{3}$ of the main river to the sea.

SULIOTS, a tribe who inhabited the valley of the Acheron, in the pashalik of Janina (*Epirus*) in European Turkey, are a mixed race, being partly of Hellenic and partly of Albanian origin. They are the descendants of a number of families who fled from their Turkish oppressors to the mountains of Suli (whence they derive their name) during the 17th century. In this obscure corner of the Turkish empire they prospered; and toward the close of the 18th c., numbered 560 families, inhabiting 90 hamlets. For about 51 years they heroically resisted the encroachments of Ali Pasha (q.v.) of Janina upon their independence, the very women taking part in the strife. Vanquished in 1803, they retreated to Parga, and afterward to the Ionian islands, where they remained till 1820, when their old oppressor, Ali Pasha, finding himself hard pressed by the Turks, invoked their aid, offering them guaranties for his faith, and his grandson as a hostage. Eager to return to their cherished home, they accepted these terms, and under Marcos Bozzaris (q.v.), maintained a long and desperate conflict with the Turks, but were ultimately forced again to flee from their country, and take refuge to the number of 3,000 in Cephalonia, though a large remnant preferred to skulk in the neighboring mountains. Though they took a glorious part in the war of Greek independence, their country was not included by the treaty of 1829 within the Greek boundary-line; but most of them established themselves in Greece, where their leaders were raised to important offices. The old seat of the Suliots lies in a portion of Epirus which the Berlin congress of 1878 recommended to be restored to Greece.—See Perriæbos's *History of Suli and Parga* (2d Greek ed., Venice, 1815; Eng. trans. 1823); and Ludemann's *Wars and Ballads of the Suliots* (Leip. 1825).

SUL'LA, L. CORNELIUS, surnamed by himself FELIX, the ablest Roman after the younger Scipio until the appearance of Julius Cæsar, was b. 138 B.C. His family was a member, but not a distinguished one, of the Cornelian gens, or "clan." In 107 B.C., he was elected questor, and sent to Africa with the cavalry that the consul Marius (q.v.) required for prosecuting the Jugurthine war. He rapidly acquired a brilliant reputation as an officer, and crowned a series of important services by inducing Bocchus, the Mauritanian king, to surrender Jugurtha, whom he brought in chains to the Roman

camp (106 B. C.). Marius was not over well pleased at the distinction achieved by his subordinate. In the campaigns that followed (104-101 B. C.) against the Cimbri and Teutones, Sulla's reputation continued to rise, although Marius was still regarded (and with justice) as the first general of the state. For several years after the destruction of the barbarians, Sulla lived quietly, taking no part in public affairs; but in 93 B. C. he stood for the pretorship, and won it by a liberal distribution of money among the people. Next year, he was sent to Cilicia as propretor, to replace Ariobarzanes on the throne of Cappadocia, from which he had been driven by Mithridates. On his return to Italy (91 B. C.), the long smoldering animosity between Marius and him was on the point of bursting forth, but the terrible *Social war* forced all Romans to postpone their quarrels until the common danger had been averted. Both Marius and Sulla commanded armies in this great struggle; but the successes of Sulla threw those of Marius into the shade, and the mortification of his rival was deep and bitter. In 88 B. C., Sulla was elected consul along with Q. Pompeius Rufus, and the senate conferred on him the command of the Mithridatic war. But this was a command that Marius himself passionately desired, and when he heard that Sulla had obtained it, he rushed headlong into treason and civil war.

Here it may perhaps be necessary to observe that Marius and Sulla were not only personal rivals, but the leaders of opposite political parties. The former, a man of humble origin (see MARIUS), was a rough, stubborn, irascible, and illiterate *plebeian*; the latter, a finely cultivated *patrician*, subtle and sagacious in policy, and winning in manners. In the terrible scenes that ensued, although Sulla showed himself by far the fiercer and more sanguinary of the two, it should not be forgotten that it was Marius who commenced the contest. Allying himself with the tribune P. Sulpicius Rufus, a political adventurer in difficulties, Marius placed himself at the head of the new Italian party, on which the rights of Roman citizenship had been conferred, and hoped to force the senate to recall the appointment of Sulla to the command of the expedition to the east. Sulla was compelled to flee to Nola in Campania, where his camp then was; but finding the soldiers full of enthusiasm, he resolved to lead them against the pseudo-government that had been established at Rome. The story of the overthrow of the Marian party, the expulsion of Marius, and his subsequent wanderings in Africa, etc., are well known, and intimately as these events are inwoven with the fortunes of Sulla, cannot be repeated here. Suffice it to say, that after settling affairs at Rome as well as he could, Sulla embarked for the east (87 B. C.), and was away for four years. Most of his fighting, however, was done in Greece against Archelaus, an ally of Mithridates, whom the latter repeatedly subsidized with men and money. Athens was stormed and plundered (86 B. C.), and Archelaus himself was defeated with frightful slaughter at Chæroneia in the same year, and again in the neighborhood of Orchomenos (84 B. C.). Sulla now crossed the Hellespont, crushed Fimbria, a general sent out by the Marian party (which in Sulla's absence, had again got the upper hand in Italy), forced Mithridates to sue for peace, and after extorting heavy contributions from the cities of Asia Minor, sailed for Italy, and landed at Brundisium in the spring of 83 B. C. Marius was now dead, but his party were strong in numbers, if not in organization; yet, before the close of 82 B. C., the Marian party in Italy was utterly crushed. In Spain, however, under the gallant and high-souled Sertorius (q. v.), it held out for ten years longer.

When Sulla felt himself master of the situation, his thoughts turned to revenge. Then followed the fearful period of the *proscriptions* (81 B. C.)—a virtual "reign of terror" throughout Italy, the object of which was literally to extirpate the Marian party. In this, however, it was only partially successful; and the next generation saw that party rise to more splendid predominance than ever in the person of Julius Cæsar (q. v.), nephew of old Marius. In 81 B. C., Sulla got himself appointed dictator, an office which he held until 79 B. C. This period was signalized by his framing a series of laws—often spoken of collectively as the "Sullan legislation"—the design of which was to make the senate and the aristocracy as vigorous and powerful as in the times of the Punic wars, but which utterly failed of its end.

On resigning his dictatorship, Sulla retired to his fine estate at Puteoli, to enjoy at his ease those sensual pleasures to which he had been deeply addicted from his earliest manhood. Literature, wine, and women were luxuries in which he had always indulged, but now he wholly devoted himself to them—in a sort of *swinish* manner. It is strange to reflect that the man who undertook to legislate with the view of mending the public morals, should himself have surpassed in profligacy all his contemporaries. What more convincing proof could we have that morality in Rome had ceased to be more than a name! Sulla's debaucheries hastened his end. He died 78 B. C., when only 60 years of age, of the disgusting disease known as *morbus pediculosus*.

SULLIVAN, a co. in s. w. Indiana, having the Wabash river for its w. boundary separating it from Illinois; 440 sq. m.; pop. '90, 21,877, chiefly of American birth. It is intersected by the Evansville and Terre Haute and the Indiana and Illinois Southern railroads; drained by the Wabash and Busseron creek. Co. seat, Sullivan.

SULLIVAN, a co. in n. Missouri, crossed by the Burlington Route and the Quincy, Omaha, and Kansas City railroads, and drained by Musclev river, the e. fork of Medicine creek, and the middle and w. forks of Locust creek; 656 sq. m.; pop. '90, 19,000. Co. seat, Milan.

SULLIVAN, a co. in s.w. New Hampshire, bounded by the Connecticut river on the w., and partly by lake Sunapee, on the e., intersected by the Boston and Maine railroad, drained by the Ashuelot and Sugar rivers; 547 sq. m.; pop. '90, 17,304. The surface bordering the Connecticut is level. Co. seat, Newport.

SULLIVAN, a co. in s.e. New York, having the Delaware river for its w. and s.w. boundary, separating it from Pennsylvania; 911 sq.m.; pop. '90, 31,031. Co. seat, Monticello.

SULLIVAN, a co. in n.e. Pennsylvania, drained by the Susquehanna river, Loyalsock and Muncy creeks; 446 sq.m.; pop. '90, 11,620. Co. seat, Laporte.

SULLIVAN, a co. in n.e. Tennessee, bordered by Virginia, crossed by the East Tennessee, Virginia and Georgia railroad, drained by the Holston river and its branches; 410 sq.m.; pop. '90, 20,879. Co. seat, Blountville.

SULLIVAN, ALEXANDER, b. Me., 1846, of an Irish family; studied law in New York, and has been for a number of years in successful practice in Chicago. He was an active abolitionist and an earnest advocate of negro suffrage, and until 1872 a republican. Being a strong friend of Horace Greeley, he supported the liberal movement, and eventually joined the democrats. In the presidential campaign of 1884, however, he returned to the republicans, and made numerous speeches for Mr. Blaine. He became pres. of the Irish National League of America on its formation.

SULLIVAN, ARTHUR SEYMOUR, composer, b. in London, May 13, 1842. He studied at the Royal Academy of Music, and at the Leipsic Conservatorium, and returning to London became organist at St. Michael's church, Chester square, London. In 1874-'6 he organized and conducted the band of the Royal Aquarium company, and conducted the Glasgow and Leeds Festivals in 1880-'3. In 1876-81 he was principal of the National Training school at South Kensington, and since 1880, a member of the Council of the Royal College of Music. In 1878 he received the decoration of the Legion of Honor, and was knighted in 1883. Cambridge gave him the degree of Mus. Doc. in 1876, and Oxford in 1879. His fame rests chiefly upon his light operettas, to which Gilbert contributed the text. Their beauty of melody, skilled treatment, and humor and quaintness of style have never been equalled in comic opera. They are: *Cox and Box*, London, 1867; *Trial by Jury*, 1875; *The Sorcerer*, 1877; *H. M. S. Pinafore*, 1878; *The Pirates of Penzance*, 1880; *Patience*, 1881; *Iolanthe*, 1882; *Princess Ida*, 1884; *The Mikado, or the Town of Titipu*, 1885; *Ruddygore, or the Witch's Curse*, 1887; *The Yeomen of the Guard*, 1888; and *The Gondoliers, or the King of Barataria*, 1889. He has also written two oratorios: *The Light of the World*, 1873, and *The Martyr of Antioch*, 1880; several cantatas and overtures; incidental music to *The Tempest*, 1862; *The Merchant of Venice*, 1871; *The Merry Wives of Windsor*, 1874; *Henry VIII.*, 1878; and *Macbeth*, 1888; anthems, songs, and part-songs. In 1891 he produced at the Haymarket, London, the grand opera in English, *Ivanhoe*, which met with great success.

SULLIVAN, BARRY, tragedian, was born in Birmingham in 1824. He made his first appearance on the stage at Cork, in 1840. After studying for some time in Ireland, he joined the company of the Theatre Royal, Edinburgh, and remained there several seasons, advancing rapidly in his profession. In 1852 he appeared at the Haymarket Theatre, London, as Hamlet, with marked success. Later he had engagements at the St. James, Sadler's Wells, and Drury Lane. In 1857 he visited America, and was warmly received in the United States and Canada. In 1861 he went to Australia, where his success was so great, that he played nearly one thousand nights in Melbourne alone. He then visited India, and completed his tour of the world in 1866. In 1869 and 1870 he was lessee of the Holborn theater, afterwards making a tour in America and Australia. He made a second visit to the U. S. in 1875, and died 1891.

SULLIVAN, JOHN, LL.D., 1740-95; b. Me.; in early life was a successful lawyer, but held his profession subservient to his zeal for American liberty. He was a member of the first continental congress; and through the darkest periods of the revolutionary war, he ranked among the ablest leaders of the American armies. In the siege of Boston he was next in command to Gen. Lee. When, in the battle of Long Island, in 1776, Gen. Greene was disabled by sickness, Sullivan was selected to command his division of the army. Serving afterward under the immediate supervision of Washington, Gen. Sullivan was distinguished for his discretion and valor in the battles of Trenton, Princeton, Brandywine, and Germantown. In 1778 Washington and count d'Estaing arranged for the French fleet to attack the British near Rhode Island, and Sullivan was sent with a large force to co-operate in besieging Newport. On the day appointed for the combined attack, a violent storm so shattered the French vessels that they withdrew from the contest. After defeating the English in one engagement, the American forces retired from Rhode Island. In 1779 Sullivan was sent with a large force into western New York to take vengeance upon the hordes of Indians and Tories who, besides other atrocities, had massacred the inhabitants of Wyoming and Cherry valley. The savages were dispersed, many were killed, and their villages destroyed. In 1780 Gen. Sullivan resigned his commission and returned to New Hampshire and to his profession of the law. After successfully filling many important civil and judicial offices, died at Durham, N. H.

SULLIVAN, JOHN LANGDON, 1777-1865, b. Maine; studied canal construction in England and on the continent. He was agent and engineer of the Middlesex canal, 1804-11. He was associate civil engineer of the U. S. board of internal improvements, 1824-25, and published reports on the feasibility of a canal through the Alleghanies. He afterwards practised medicine, adopting the homeopathic system. In 1814 he received a patent for the invention of the steam tow-boat, being given priority over Robert Fulton.

SULLIVAN, JOHN LAWRENCE, pugilist, was born at Boston, Mass., in 1858. As a boy he worked as a day laborer, but in 1879 began to spar in public without attracting attention until 1880, when in a contest with the veteran Joe Goss at the Boston Music Hall, Sullivan showed remarkable qualities as a fighter. In the same year he visited Cincinnati and won a boxing-match with John Donaldson. In February, 1882, Sullivan fought his first prize-fight, defeating "Paddy" Ryan, a leading pugilist. Subsequent contests in which he was equally successful were those against James Elliott (1882); "Tug" Wilson (1882), Herbert Slade (1883), Alfred Greenfield (1884), and Ryan again (1886). In 1888 Sullivan met Charles Mitchell in a prize-fight near Chantilly, France, and fought thirty-nine rounds to a draw. In 1889, he won a fight with Kilrain, but was beaten in 1892 by James Corbett. In 1890-91 he profited by his notoriety, appearing as an actor in a play called *Honest Hearts and Willing Hands*.

SULLIVAN'S ISLAND, a large island, 6 m. below Charleston, S. C., between the harbor and ocean, the site of Fort Moultrie, now dismantled, and of the summer residences of the wealthy inhabitants. When Fort Moultrie was evacuated by Maj. Anderson, Dec. 26, 1860, several batteries were erected on the shore of this island, bearing upon the channel and Fort Sumter.

SULLIVANT, WILLIAM STARLING, LL.D., 1803-73; b. Franklinton, Ohio; graduate of Yale college, 1823; became a surveyor and resident of Columbus, and published catalogues and specimens of plants and mosses. He has made contributions to the bryology and hepaticology of North America; to Asa Gray's *Manual of Botany*, and numerous other works, besides contributing valuable papers to scientific journals. Associated with L. Lesquereux he published *Musci Boreali-Americani*, consisting of 350 species and varieties of dried mosses. He discovered a plant of the saxifrage family on which was founded the genus *Sullivantia*.

SULLY, a co. of S. Dakota, bounded on the w. by the Missouri river, and drained by its branches; 1050 sq. m. Pop. '90, 2412. Co. seat, Ouida.

SULLY, JAMES, was born at Bridgewater, Somersetshire, in 1842, and educated in the Independent college, Taunton, the Regent's Park college and the university of Göttingen. In 1892 he became Grote prof. of philosophy of mind and logic in University college, London. He is the author of *Sensations and Intuition: Studies in Psychology and Aesthetics* (1874); *Pessimism: a History and a Criticism* (1877); *Illusions* (1883); *Teachers' Handbook of Psychology* (1886); *The Human Mind* (1892); *Studies of Childhood* (1895).

SULLY, MAXIMILIEN DE BETHUNE, Duke of, the celebrated minister of Henry IV. of France, was the second son of François, baron de Rosny, and was born at Rosny, near Mantes, in 1560. The Rosny family, an offshoot from the great house of Flanders, was never possessed of much wealth or influence, and had severely deteriorated in both respects during the early religious wars. Sully was at an early age committed to the care of Henry of Navarre, the head of the Huguenot party, which not only obtained for him an excellent education, but laid the foundation of a companionship which lasted, without intermission, till Henry's death. After narrowly escaping during the St. Bartholomew massacre, he accompanied his patron in his flight from court (1575), and during the civil war which followed, exerted himself to the utmost, by daring valor in the field and otherwise, to serve the master for whom he cherished the most absorbing devotion. After Henry's authority had been well established, Sully, who had for some years previous been his trusted adviser, became (1597) counselor of state and of finance. The financial affairs of the country were then in a frightful condition; from the chief of the department down to the very lowest country agent, the administration was an organized system of pillage, and but a small percentage of the taxes levied found its way into the imperial treasury. The baron de Rosny was the very man to remedy this state of matters; rude, obstinate, and haughty, but at the same time resolute, active, indefatigable, wholly devoted to his master's interests; and backed by the influence of Gabrielle d'Estrees, and by Henry's own clear-sighted convictions, he cared nothing for the clamor and hatred of the court, which had largely profited by the former state of chaos. Not content with regulating the affairs of the revenue from the seat of power, he made a tour through the chief provincial districts, armed with absolute authority, personally examined the accounts, dismissed or suspended delinquents, and largely replenished the treasury with the ill-gotten wealth which he compelled them to disgorge. By indomitable perseverance, he little by little brought the affairs of the country into an orderly state; although in the diminution of the expenditure his efforts were by no means so successful, as the king, his mistresses, and the other companions of his pleasures, combined to oppose all retrenchment as far as they were concerned. In 1596 the disposable revenue of the state was 7 to 9 millions; in 1609 it was no less than 20 millions, with a

surplus of 20 to 22 millions in the treasury, and the arsenals and fleet in a state of excellent equipment. Sully, however, was more than a mere financier; he had the supreme charge of various other branches of the administration, zealously promoted agriculture by diminishing the taxes of the peasantry, encouraging export trade, draining marsh-lands, and constructing numerous roads, bridges, and causeways. Sully was the servant of the king and government alone, and was of necessity disliked by the people for his severity, by the Catholics for his religion, and by the Protestants for his invariable refusals to sacrifice the smallest jot of his master's or the country's interest for their sake. Accordingly, with the death of Henry, his career of supremacy was at once ended, and he was forced to resign the superintendence of finance, Jan. 26, 1610, though he retained his other high offices, and was presented by Marie de Medicis with 300,000 livres as acknowledgment of his services. He had been created duke of Sully and peer of France in Feb., 1606. Sully wrote three treatises on war and police, which are lost, and two pieces of verse which are extant; but the work which will ever be connected with his name is the *Mémoires des sages et royales (Economies d'Etat, etc., de Henry le Grand)*; a dull, wearisome, and disorderly collection of writings, but of priceless value to a historian of Henry IV.'s time. Sully printed the first two volumes of the *Mémoires* at his own château of Sully in 1634; the third and fourth were published at Paris in 1662, and the whole has been several times republished. Sully died at Villebon, Dec. 22, 1641.

SULLY, THOMAS, 1783–1872, b. England; brought to this country by his parents. From 1798–1804 he resided in Charleston, S. C., studied art and produced some juvenile pieces. He then settled in Richmond, Va., and later in New York, in both places practicing the profession of a portrait painter with great success. In 1810 he removed to Philadelphia, where the rest of his life was spent, with exception of visits abroad, in one of which he painted an excellent portrait of queen Victoria. The Boston Museum possesses his most ambitious work, "Washington Crossing the Delaware." Among his best portraits were those of Cooke the tragedian as Richard III., Fanny Kemble, Dr. Rush, Decatur, Jefferson, and Lafayette.

SULLY-PRUDHOMME, RENÉ FRANÇOIS ARMAND, French poet, was born in Paris in 1839, was educated at the Lycée Bonaparte, and spent some time as a lawyer's assistant. His first volume of poems appeared in 1865. Other collections of poems are, *Les Épreuves* (1866); *Les Solitudes* (1869); *Les Destinées* (1872); *Les Vaines Tendresses* (1875); *La Justice* (1878); and a translation of Lucretius, *De Natura Rerum* (1869). He was elected to the Academy in 1881. An edition of his works was published (1883–4).

SULMONA, or **SOLMONA**, a city of southern Italy, province of Aquila, in Abruzzi. Pop. '81, 17,600. It is situated in a vast fertile plain watered by two rivers, and bounded by hills. It is the ancient *Sulmo*, the birth-place of Ovid, and of Pope Innocent VII.

SULPHATES. See **SULPHURIC ACID**.

SULPHIDES, METALLIC, formerly known as *sulphurets*, are combinations of sulphur with a metal. Many of them occur native, and form highly valuable ores. They are all solid at ordinary temperatures, and, with the exception of those of potassium, sodium, calcium, strontium, barium, and magnesium, are insoluble in water; they are, moreover, conductors of electricity. Many of them, especially of those that occur native, exhibit very brilliant and characteristic colors. The same metal may have several sulphides, and in general there is a sulphide for each oxide. The sulphides are, however, sometimes the more numerous. Most of these compounds may be fused at a heat a little above redness, and if the air be excluded, the protosulphides (those containing one atom of sulphur and one atom of metal) remain unaffected; but many of the higher sulphides, such as the bisulphide of iron, FeS_2 , and the bisulphide of tin, SnS_2 , give off an atom of sulphur, and are reduced to protosulphides. If, however, there is a free admission of air or of oxygen gas to the heated sulphides, they are all decomposed, the sulphur becoming oxidized, and passing off as sulphurous acid, SO_2 , while the metal usually remains in combination with oxygen. When heated before the blowpipe, most of the sulphides evolve an odor of sulphurous acid, and very small quantities of soluble sulphides may be detected in neutral or alkaline solutions by the addition of a solution of nitroprusside of sodium, $\text{Na}_4(\text{CN})_6(\text{NO})_2\text{Fe}_2 + 4\text{H}_2\text{O}$, when a magnificent purple color, which, however, is not permanent, is evolved. It has very recently been discovered by Mr. Barrett, and announced in his paper, "On some Physical Effects produced by the contact of a Hydrogen Flame with various Bodies," in the *Philosophical Magazine* for Nov., 1865, that the sudden appearance of a blue color when the hydrogen flame is brought in contact with a body containing sulphur, is a most delicate test for the presence of this element, detecting it even when the nitro-prusside of sodium test fails. By this test Mr. Barrett detected $\frac{1}{1000000}$ of a grain of sulphur.

The sulphides are prepared in various ways, of which it is sufficient to notice the most important. (1.) The protosulphides of the metals of the alkalies and alkaline earths may be obtained by decomposing their sulphates by igniting them in closed vessels with charcoal, the oxygen being removed in the form of carbonic oxide. (2.) Many of the metals, when heated with sulphur, combine directly with it; sulphide of iron, for example, is usually prepared in this manner. (3.) Hydrated sulphide of tin, titanium, molybdenum.

tungsten, vanadium, arsenic, antimony, bismuth, copper, lead, mercury, silver, gold, and platinum with its allied metals may be obtained by passing a stream of sulphuretted hydrogen through neutral or acid solutions of their salts, when they are precipitated in an insoluble form; and the hydrated sulphides of zinc, iron, manganese, cobalt, and nickel may be prepared by double decomposition, by mixing a solution of the salt of the metal with a solution of a sulphide of one of the metals of the alkalies, as, for example, sulphide of potassium: thus, sulphate of zinc, if mixed with sulphide of potassium, yields sulphate of potash, which remains in solution, and sulphide of manganese, which falls as an insoluble precipitate. "In many cases," says prof. Miller, "the atoms of these hydrated sulphides are characteristic of the metal; for example, the hydrated sulphide of zinc is white; that of manganese, flesh red; those of cadmium, arsenic, and persulphide of tin are yellow; that of tersulphide of antimony is orange red; and that of hydrated protosulphide of tin is chocolate brown. The sulphides of molybdenum, rhodium, iridium, and osmium are brown, each with its peculiar shade, while in a large number of instances—including the sulphides of iron, cobalt, nickel, uranium, vanadium, bismuth, copper, lead, silver, mercury, gold, platinum, and palladium—the precipitated sulphides are of a black, more or less pure."—*Inorganic Chemistry*, 2d ed. 1860, p. 322. A recollection of the colors of these precipitates will save the young chemist a large amount of labor in testing for the presence of the metals.

SULPHOCYAN OGEN AND THE SULPHOCYANIDES. The former of these terms is given to a monobasic radical, SCN, or CyS, which has never yet been isolated, but which forms an acid compound, known as hydrosulphocyanic acid, HSCN, with hydrogen, and yields numerous metallic salts. These salts, known as sulphocyanides, may be represented by the general formula, M,SCN, where M represents any metal. The sulphocyanides of potassium, sodium, and ammonium are crystallizable and soluble in water; those of the heavy metals are comparatively insoluble. These salts do not possess the poisonous character of the cyanides. *Sulphocyanide of potassium*, KSCN, is anhydrous, but very deliquescent, and occurs in long streaked colorless prisms, somewhat resembling niter both in appearance and taste; it is extremely soluble in water, and fuses on the application of a gentle heat. The *sulphocyanide of mercury* is a white powder which possesses the property of swelling or growing in size to an almost incredible degree when moderately heated, so as to decompose it into a mixture of mellon, $C_6H_5N_3$, with a little sulphide of mercury. The resulting mass often assumes a most fantastic shape, and is sufficiently coherent to retain its form; it is of a yellow color externally, but black within. It is this sulphocyanide which is the ingredient of the well-known toy known as "Pharaoh's serpents." Each serpent consists of a little cone of tinfoil, resembling a pastille in shape, and filled with the above-named compound. On lighting the cone at the apex, there begins to issue from it a thick serpent-like coil, which continues twisting and increasing in length to an extraordinary degree, the serpent-like shape resulting from the salt being burned in the tinfoil cone. The compound is readily obtained by precipitating a strong solution of pernitrate of mercury with sulphocyanide of ammonium, which is most cheaply prepared by Mr. Wood's method from bisulphide of carbon.

SULPHOVINIC ACID, or ETHYL HYDROGEN SULPHATE, $C_2H_5 \cdot HSO_4$, is formed by mixing alcohol with an equal bulk of oil of vitriol. Great heat is evolved, and the two bodies enter partially into combination; this new compound acid possessing only half the saturating capacity of sulphuric acid. In connection with the theory of the formation of ether from alcohol and sulphuric acid, it may be observed that this sulphovinic acid is developed as an intermediate product, only when the temperature is raised to 212° F. This is one of the class of bodies to which the term *acid sulphuric ethers* is applied.

SULPHUR (symb. S, eq. 16—new system, 32—sp. gr. of rolled sulphur, 1.98 [see ATOMIC WEIGHTS], and of amorphous sulphur, 1.957; sp. gr. of vapor, 6.617 at 842° F. (450° C.), and 2.2 at 1680° F. (860° C.), atmospheric air being the unit of comparison for the vapor) is one of the most important of the non-metallic elements. At an ordinary temperature, it exists as a solid, brittle, tasteless, and inodorous body, of a characteristic yellow color, and insoluble in water. A piece of solid sulphur, heated to a temperature of 239° F. (115° C.), fuses into a thin yellow liquid; while in closed vessels, it may, by a further heat, be distilled, the boiling-point being about 842° F. (450° C.), and at this temperature it yields a deep yellow vapor, of sp. gr. 6.617. When the sulphur-vapor comes in contact with cold air, it condenses in the form of a fine yellow powder, known as *flowers of sulphur*. If fused sulphur be rapidly cooled, it solidifies into a compact mass, of a granular crystalline texture, and if, in its liquid state, it be allowed to run into cylindrical wooden molds, we obtain it in the ordinary form of roll-sulphur, or common brimstone; if, on the other hand, it be allowed to cool slowly, it crystallizes in long, glistening, deep, yellow, oblique prisms, with a rhombic base, which, however, soon lose their most characteristic properties. As native sulphur is frequently met with in yellow crystals, whose form is derived from the octahedron with a rhombic base, it is obviously a dimorphous substance. It has been already stated that sulphur fuses at 239° F.; from that temperature up to 302° F. (150° C.), it forms a yellow, transparent, limpid liquid; as the heat increases, the color becomes brown, and almost black, and the liquid viscid, these changes being very distinctly seen at 482° F. (250° C.). If the external application

of heat be steadily continued, it will be found that for a while the temperature remains constant, but it afterwards rises, and at nearly 752° F. (400° C.) the sulphur again liquefies, although less completely than when first melted. If suddenly cooled by pouring it, in a slender stream, into cold water, we obtain a spongy, tenacious, and plastic mass, which may be drawn out into elastic threads, whose color, after they have cooled, varies from an amber to a deep brown color, according to the heat that has been employed. After some hours the ductile sulphur loses its characteristic properties, increases in density, and returns to the brittle form; or, if heated to 212° F. (100° C.), suddenly returns to the brittle condition; the temperature rising to 230° F. (110° C.) during the change. Hence, sulphur may be obtained in three (at least) allotropic states, which are distinguished by the symbols $S\alpha$, $S\beta$, $S\gamma$. The first variety, $S\alpha$, is the native octahedral crystal of sulphur; it may be obtained artificially by dissolving sulphur in bisulphide of carbon, or chloride of sulphur, and submitting the solution to spontaneous evaporation. These crystals are semi-transparent, of an amber-yellow color, and undergo no change on exposure to the air. The second variety, $S\beta$, is the oblique prismatic crystal already described as being formed when fused sulphur cools slowly. The best method of obtaining these crystals is to melt a few pounds of sulphur, and allow it to solidify on the surface. On perforating the external crust with a hot wire, and pouring out the sulphur that remains liquid, the interior of the cavity is found to be traversed in all directions by these crystals, occurring as transparent brownish needles, having a specific gravity considerably less even than that of roll-sulphur. On exposure to the air they soon lose their coherence, and form an opaque and crumbling mass, consisting of minute rhombic octahedra. This conversion of the prismatic into the octahedral form takes place immediately if the prisms are immersed in bisulphide of carbon. The third variety, $S\gamma$, is the plastic amorphous sulphur, which has been sufficiently described. If sulphur be frequently heated to 600° , and suddenly cooled, a black variety of this element is produced; and a red variety has been obtained, but the redness is now supposed to be due to the presence of a trace of some fatty body.

Sulphur is a bad conductor of heat, and the mere heat of a warm hand often causes it to crackle, and even to fall to pieces, from the unequal expansion. It is an insulator of electricity, and becomes negatively electric by friction. It is slightly soluble in alcohol, ether, and the fatty oils; its best solvents being the bisulphide of carbon and chloride of sulphur. When heated in the air, it takes fire at about 473° F. (245° C.), burning with a blue flame, and becoming converted into sulphurous acid, whose pungent suffocating fumes are characteristic of sulphur. This element is second only to oxygen in its powerful affinity for other elements, with most of which it unites, and often in several proportions. With most of the metals it combines very readily, and in some cases, with a development of light and heat; thus, silver and copper burn in sulphur-vapor just as iron-wire or zinc-foil burns in oxygen. In consequence of its power, with the aid of heat, of forming sulphurous acid with the oxygen of the air, and thus rendering the latter incapable of supporting combustion, burning sulphur may be usefully employed for the extinguishing of fire—as, for example, in chimneys.

Sulphur occurs very widely distributed in the mineral kingdom, partly free and partly combined with other elements. The free sulphur is either found pure in regularly formed crystals, or intimately mixed with earthy matters. The principal sources of crystalline sulphur are Urbino in Italy, Girgenti in Sicily, and Radoboy in Croatia; while the earthy sulphur is mainly derived from Italy, Moravia, and Poland. Iceland is rich in both varieties, but the mineral wealth of that island remains almost unworked. At present, by far the greatest quantity of the sulphur employed in Europe comes from Sicily; and, as a general rule, it is abundant in volcanic districts. In the form of sulphide, sulphur occurs abundantly in combination with iron, copper (iron and copper pyrites), lead (galena), zinc (blende), etc., the bisulphide of iron (or iron pyrites) furnishing most of the sulphur that is employed in the manufacture of sulphuric acid. Sulphur is still more extensively distributed in the form of sulphates, the sulphates of lime, magnesia, baryta, etc., being abundant natural productions. In the vegetable kingdom, sulphur is a constituent (although only to a small amount) of the albuminous bodies which are so widely diffused in plants; and of certain volatile irritant oils, as those of mustard, garlic, asafetida, etc.; and, moreover, the vegetable juices contain it in the form of certain sulphates. In the animal kingdom, it is not only a constituent of the albuminous, fibrinous, and gelatinous tissues, but of the hair, saliva, bile, urine, etc. The two animal substances in which it is most abundant are cystin (q.v.), an occasional constituent of urinary calculi, and taurine (q.v.), a constituent of the bile, in both of which it forms a large fraction of the entire weight.

It would be out of place in this article to enter into details regarding the *extraction* or *preparation* of sulphur. It is sufficient to state that the grosser impurities are removed by crude processes of fusion and distillation at or near the place from whence it is obtained. That which is imported into America undergoes further purification. What is called *refined sulphur* is that purified by distillation in a large cast-iron still, and condensed in a receiver kept cool. When the vaporized sulphur is condensed in a large chamber, it is obtained in the form of *sublimed sulphur*, or *flowers of sulphur*; but as the walls get hot, it melts and collects on the floor, and is run into cylindrical wooden molds, from which, when cool, it is taken out as *roll* or *stick sulphur*. The residue left in the retort is a mixture of sulphur with various impurities. Under the names of *black*

sulphur, or *sulphur vivum* (commonly inquired for at the chemist's under the title of *sulphur of try*), it is used in veterinary medicine, and for the purpose of dressing moldy hops. Sulphur is thrown down from certain of its compounds (as from a strong solution of a polysulphide of calcium, sodium, or potassium) by dilute hydrochloric acid; it falls as a grayish-white, very fine, light powder, known in the *Materia Medica* as *milk of sulphur*, or *precipitated sulphur*. For the method of obtaining sulphur from iron pyrites, we must refer the reader to Miller's *Inorganic Chemistry*, 2d ed. p.154. The proceeding is usually conducted on a large scale, 2,000 tons of pyrites being roasted at once, the roasting extended over five or six months, and the final result being about 20 tons of sulphur. The most common impurities met with in ordinary commercial sulphur are selenium and realgar (bisulphide of arsenic). Flowers of sulphur frequently exhibit a slight acid reaction, in consequence of a little sulphurous acid clinging to them. By rinsing them with water, this impurity is at once removed.

Sulphur is extensively employed in the arts and manufactures; as in the manufacture of matches, gunpowder, etc. When converted into sulphurous acid, it is employed as a powerful bleaching agent, and also for the destruction of insects, fungi, etc.; but its chief consumption is in the manufacture of sulphuric acid.

Sulphur unites with oxygen in two proportions, *sulphur dioxide*, SO_2 , and *sulphur trioxide*, SO_3 . These are true acid-forming oxides, for when they are brought in contact with water they yield respectively *sulphurous* and *sulphuric acids*.

The following are the oxyacids of sulphur :

| | |
|---------------------------------------------------------------|------------------------------------|
| Hyposulphurous acid..... | H_2SO_3 . |
| Sulphurous acid..... | H_2SO_3 . |
| Sulphuric acid..... | H_2SO_4 . |
| Thiosulphuric acid (formerly called Hyposulphurous acid)..... | $\text{H}_2\text{S}_2\text{O}_3$. |
| Dithionic acid..... | $\text{H}_2\text{S}_2\text{O}_6$. |
| Trithionic acid..... | $\text{H}_2\text{S}_3\text{O}_6$. |
| Tetrathionic acid..... | $\text{H}_2\text{S}_4\text{O}_6$. |
| Pentathionic acid..... | $\text{H}_2\text{S}_5\text{O}_6$. |

The last five of these acids have never been obtained in the anhydrous form. We shall only notice the most important members of this group, viz., the second, third, and fourth, and of these, the third, *sulphuric acid*, is so extremely important, that it is discussed in a special article. The last four derive the essential portion of their name from the Greek word *theon*, sulphur.

SULPHUR DIOXIDE, or **SULPHUROUS ANHYDRIDE**, SO_2 , occurs under the ordinary relations of temperature and pressure as a colorless gas, possessing the suffocating odor of burning sulphur. In its concentrated form it is quite irrespirable, and in a diluted state it excites cough, and produces the symptoms of an ordinary catarrh. It is not only incapable of burning, but it rapidly extinguishes the flame of burning bodies. It is very freely soluble in cold water, which at 32°F . (0°C .) takes up nearly 69 times its volume of the gas, while at 68°F . (20°C .) it only takes up 36 volumes; the solution known as *aqueous sulphurous acid* having the same smell and taste as the gas. By the action of cold, sulphurous acid may be condensed to a colorless transparent limpid liquid, which has been solidified to a white, snow-like mass. The specific gravity of the gas is 2.247 (atmospheric air being the unit), and that of the liquid is 1.49 (water being the unit), the solid being considerably heavier. Although dry sulphurous acid gas and dry oxygen, when mixed, exert no action on one another, there are many conditions under which sulphurous acid rapidly absorbs oxygen, and is converted into sulphuric acid. This action takes place under the influence of hydrated nitric acid, iodic acid, and certain metallic oxides. For example, dioxide of lead, when immersed in the gas, burns, and is converted into white sulphate of lead, $\text{PbO}_2 + \text{SO}_2 = \text{PbSO}_4$. Hence, sulphurous acid is a powerful reducing or deoxidizing agent. This gas is a common and abundant product of volcanic action, and is occasionally met with in solution in the springs in volcanic regions. It may be prepared artificially by simply burning sulphur in the air or in oxygen gas, or by heating in a flask 4 parts of flowers of sulphur mixed with 5 parts of powdered black manganese, sulphurous acid and sulphide of manganese being the products, as shown by the equation $2\text{S} + \text{MnO}_2 = \text{SO}_2 + \text{MnS}$. In consequence of its solubility in water, this gas should be collected over mercury. In addition to the uses of sulphurous acid as a bleaching agent, it is valuable both as a disinfectant agent and as a powerful antiseptic; its latter property has been applied to the preservation of meat, which, after exposure to this acid, will keep fresh for years, if it be inclosed in metallic canisters filled with nitrogen, to which a little binoxide of nitrogen has been added, to remove any trace of oxygen. But by far its most important use is, as a first stage in the manufacture of sulphuric acid. In combination with bases, this acid forms the *sulphites*—a class of salts which, excepting the sulphite of soda, are of little practical importance, except for their power, when moist, of extracting oxygen, and thus acting as reducing agents. For example, the salts of the sesquioxide of iron are reduced by them to salts of the protoxide.

HYPOSULPHUROUS ACID, now called *Thiosulphuric Acid*, $\text{H}_2\text{S}_2\text{O}_3$, as yet is only known in a state of combination with bases; for on attempting to separate the acid from the

base, the former becomes decomposed into sulphur and sulphurous acid. The most important of its salts is the *hyposulphite of soda*, $\text{Na}_2\text{S}_2\text{O}_3 + 5\text{H}_2\text{O}$, whose mode of preparation and characters are described in the article *SODIUM*. This and other soluble hyposulphites may be easily recognized by the facility with which they dissolve the haloid salts of silver, forming a solution of an extremely sweet taste, and containing a double hyposulphite of silver and soda, with an admixture of chloride, iodide, or bromide of sodium. It is this power of dissolving those salts of silver which are insoluble in water, that renders the hyposulphite of soda so important an agent in photography. The only other salt of this acid which we shall notice is the *hyposulphite of gold and soda*, $3\text{Na}_2\text{S}_2\text{O}_3 + \text{Au}_2\text{S}_2\text{O}_3 + 4\text{H}_2\text{O}$, which may be prepared by mixing concentrated solutions of 1 part of chloride of gold and 3 parts of hyposulphite of soda, and adding alcohol, when the required salt is precipitated. It is used for gilding the daguerreotype plate, and for toning the positive proof obtained in photographic printing.

With hydrogen, sulphur forms two compounds, viz., *sulphureted hydrogen*, or *hydrosulphuric acid* (q.v.), and *persulphide of hydrogen*, an oily liquid, having the smell and taste of sulphureted hydrogen, and in many of its properties having an analogy to binoxide of hydrogen. Sulphur combines with carbon to form a *bisulphide of carbon*, CS_2 , a very volatile colorless liquid, of a high refractive power, of an acrid and pungent taste, and a very disagreeable odor. It is heavier than water, in which it is insoluble, but dissolves freely in alcohol and ether, and is the best solvent for sulphur and phosphorus. Bisulphide of carbon does not occur as a natural product, but may be obtained by heating fragments of charcoal to bright redness in a porcelain tube, and passing sulphur vapor through it. Its vapor, when freely inhaled, exerts a similar anæsthetic action with those of chloroform and ether. Workmen in caoutchouc or other manufactures in which bisulphide of carbon is used as a solvent, suffer very much from prolonged exposure to its vapor, which produces headache, loss of appetite, impairment of vision and hearing, and causes general derangement of health by its deleterious action on the nervous system. Sulphur combines with chlorine in several proportions, the most important of these compounds being *monochloride of sulphur*, S_2Cl_2 , and the *dichloride of sulphur*, SCl_2 . Both of them are liquids, and are formed by the direct action of the combining elements. The monochloride is a yellow volatile liquid with a penetrating and disagreeable odor. When dropped in water, it sinks to the bottom (its spec. grav. being about 1.705), and is slowly decomposed into hydrochloric and sulphurous acids and free sulphur. It is capable of dissolving about 67 per cent. of sulphur at an ordinary temperature, and, like bisulphide of carbon, is extensively employed in vulcanizing india-rubber. The dichloride of sulphur is formed by saturating the monochloride with chlorine. It is a deep-red liquid, resembling the previous compound in most of its properties. It is decomposed by the sun's rays into the monochloride and free chlorine.

With regard to the history of sulphur and its compounds, it may be observed that sulphur seems to have been known from the earliest times, and that sulphuric acid was most probably known to the Arabians. The manufacture of English sulphuric acid dates, however, only from the 18th century. Sulphurous acid was first investigated by Stahl, Scheele, and Priestley; hyposulphuric acid was discovered by Welter and Gay-Lussac; hyposulphurous acid, by Gay-Lussac and Herschel; trithionic acid, by Langlois; tetrathionic acid, by Fordos and Gelis; and pentathionic acid, by Wackenroder. Scheele was the first who accurately studied hydrosulphuric acid, or sulphureted hydrogen.

Sulphur is used to a considerable extent and for very different purposes in medicine. It is given internally either as sublimed sulphur (flowers of sulphur) or as precipitated sulphur (milk of sulphur), in somewhat large doses, as a mild cathartic—its purgative effects being due to its stimulating the muscular coat of the intestines. In consequence of its being both gentle and sure in its action, it is the best purgative to employ in cases of piles, or in stricture or other painful affections of the rectum. The only objection to its use is that, from its becoming partly converted in the system into sulphureted hydrogen, the evacuations, and even the insensible perspiration, often become abominably fetid, and continue so for some time after the primary operation of the medicine. As a purgative, the dose is about two drams, made into an electuary with treacle or honey. It is, however, generally combined with jalap and cream of tartar.

The *confection of sulphur* of the *Pharmacopœia* is composed of sulphur, cream of tartar, and syrup of orange-peel rubbed together—the dose being from half an ounce to an ounce, or from one to two tablespoonfuls. In small doses, sulphur is of great value in cases of atonic gout and chronic rheumatism. An electuary known as the *Chelsea pensioner*, consisting of two ounces of sublimed sulphur, one ounce of powdered rhubarb, half an ounce of resin of guaiacum, one ounce of cream of tartar, half an ounce of ginger, and two drams of powdered nutmegs, with as much treacle as is necessary, in doses of one or two teaspoonfuls night and morning, is a combination of great value in these cases. It originally gained its reputation by curing lord Amherst of rheumatism, and is still a favorite remedy at Chelsea hospital. Dr. Neligan states that steaming the lower bowel, by sitting over the vapor of warm water upon which a tablespoonful of flowers of sulphur had been sprinkled, constitutes a most valuable remedy in what is popularly known as a "fit of the piles." The external use of sulphur in the form of

ointment has been already noticed in the article ITCII. It is also used externally in many other cutaneous disorders, particularly in lepra and psoriasis; and in chronic cases, its application in the form of vapor is often of great service.

SULPHURIC ACID, H_2SO_4 , is the chemical name of the liquid commercially and popularly known as *oil of vitriol*.* It is a monohydrate of sulphur trioxide, thus, $\text{SO}_3 \cdot \text{H}_2\text{O}$, and is a dense, colorless, oily liquid, without smell, of a spec. grav. of 1.846 at a temperature of 60°F . (15.5°C .), and of an intensely acid taste and reaction. It has a powerful caustic action, and chars and destroys organic matters from its strong affinity for water; and in consequence of this destructive property, it must always be handled with the greatest caution. So powerful is this affinity, that if the acid be exposed for a few days to the air in a shallow dish, so as to present a large surface, it often doubles its weight by absorbing aqueous vapor from the air; and in consequence of its possessing this property it is extensively used in laboratory operations as a desiccating agent. It mixes completely with water in all proportions, and as great heat is given out at the moment of mixture, the dilution should be performed by very gradually adding the acid to the water. When cold the mixture occupies less bulk than the two components previously occupied. This acid freezes at a temperature of -15°F . (-26°C .), and boils at 620°F . (326.5°C .) (or according to Marignac, at 640°F .), and just above the boiling-point it assumes the form of a vapor, with a spec. grav. of 2.15. Oil of vitriol, or the monohydrate, is not the only hydrate of sulphuric acid. Three others are known to exist. When the fuming oil of vitriol of Nordhausen is exposed to a low temperature, a white crystalline substance separates, which is a hydrate, containing half as much water as the common liquid acid. Its formula is $\text{H}_2\text{S}_2\text{O}_7$, or $(\text{SO}_3)_2\text{H}_2\text{O}$. Its fusing point is 95°F . (35°C .). Then, again, a mixture of 49 parts of strong liquid acid and 9 parts of water, $\text{SO}_3 \cdot 2\text{H}_2\text{O}$, freezes at 45°F . (7.2°C .), and crystallizes into splendid rhombic prisms, from which property it is often termed *glacial sulphuric acid*. It boils at 435°F . (224°C .), and its spec. grav. is 1.780. Lastly, when a very dilute acid is concentrated by evaporation *in vacuo*, at 212°F . (100°C .), till it ceases to lose weight, there will be a resulting compound, consisting of 40 parts of the real acid, and 27 of water, and represented by the formula, $\text{SO}_3 \cdot 3\text{H}_2\text{O}$. It boils at 348°F . (175.5°C .), and its spec. grav. is 1.602. There are thus no less than four hydrates of sulphuric acid—viz.: (1) the disulphuric monohydrate, $2\text{SO}_3 \cdot \text{H}_2\text{O}$; (2) the ordinary monohydrate, $\text{SO}_3 \cdot \text{H}_2\text{O}$; (3) the dihydrate, $\text{SO}_3 \cdot 2\text{H}_2\text{O}$; and (4) the trihydrate, $\text{SO}_3 \cdot 3\text{H}_2\text{O}$. The compound formerly known as *anhydrous sulphuric acid* possesses none of the characteristic properties of an acid. See SULPHURIC ANHYDRIDE; also CHEMISTRY.

Sulphuric acid in its free state is a very rare natural product; although, in combination with bases, it is common in the animal and vegetable, and abundant in the inorganic kingdom. It is known to occur free in certain American rivers, especially the Rio Vinagre, and some lakes in Tennessee and in Java; and it has been found to be a normal constituent of the saliva of *dolium galia*, a species of snail found in Sicily. In all these cases the acid is, of course, in an extremely diluted form. In plants it exists in the juices, and in animals in the blood and its derivatives chiefly in the form of sulphates of the alkalies; while in the mineral kingdom it occurs as gypsum (sulphate of lime), heavy spar (sulphate of baryta), celestine (sulphate of strontia), etc.

Sulphuric acid may be prepared on a small scale by boiling sulphur in *aqua regia*, or in nitric acid, the sulphur becoming gradually oxidized into sulphuric acid. As a general rule, however, the commercial acid is employed even for laboratory experiments.

In order to obtain the acid in a pure form, suitable for medical use or medico-legal analyses, it must be redistilled with sulphate of ammonia in a retort containing a few slips of platinum foil, the first and last portions being rejected. The distillation is attended with violent concussions, partly owing to the high specific gravity of the acid, and partly owing to its high boiling-point, and this convulsive action is moderated mechanically by the platinum slips. Sulphuric acid thus prepared according to the direction of the British pharmacopœia may be regarded as perfectly pure, presuming arsenic is not present. Strong sulphuric acid has comparatively little action on the metals except at a high temperature, when it dissolves them, and, at the same time, undergoes partial decomposition; the metal being oxidized by a portion of the acid which becomes decomposed into oxygen and sulphurous acid, and then uniting with a portion of undecomposed acid to form a sulphate. Silver, copper, mercury, arsenic, antimony, bismuth, tin, lead, and tellurium are thus acted on. Gold, platinum, rhodium, and iridium are not affected by the acid even at a boiling temperature. The more oxidizable metals, such as zinc, iron, nickel, and manganese, are readily soluble in the dilute acid, water being decomposed, and hydrogen liberated, while the oxygen of the water unites with the metal; and the metallic oxide, at the moment of its formation, combines with the sulphuric acid to form a sulphate.

The *sulphates*—or salts formed by the combination of sulphuric acid with a base—are generally composed, as in the case of green vitriol, $\text{FeSO}_4 + 7\text{H}_2\text{O}$, of 1 equivalent of acid and 1 of metallic oxide, with or without water of crystallization. With the alkalies this acid also forms acid salts, as bisulphate of potash, and in a few cases—copper,

* It received this name from having been first produced by the distillation of green vitriol (sulphate of iron); Basil Valentine being usually credited with the discovery. See ALCHEMY.

for example—it forms basic salts. The insoluble sulphates, such as that of baryta, may be obtained by precipitating a soluble salt of the base by a soluble sulphate; thus, nitrate of baryta and sulphate of soda yield an insoluble sulphate of baryta and nitrate of soda, which remains in solution. The soluble sulphates may be prepared by dissolving the oxide or carbonate in dilute sulphuric acid, in those cases in which the metal itself is not readily attacked by the acid. Sulphuric acid and the soluble sulphates are easily detected by their yielding, with a solution of a baryta salt, a white precipitate of sulphate of baryta insoluble in acids.

This acid is employed in the arts and manufactures for a large number of purposes. Its use as a desiccating agent for laboratory purposes has been already noticed, and its application to the development of oxygen gas has been described in the article on that element. But its greatest consumption, doubtless, is in the preparation of the *salt-cake*, which is used in the manufacture of carbonate of soda (q.v.).

In medicine a *dilute sulphuric acid*, formed by gradually mixing three fluid ounces of the strong purified acid with thirty-five fluid ounces of water, or *aromatic sulphuric acid* (known also as *elixir of vitriol*), prepared by mixing three ounces of sulphuric acid with a quart of rectified spirit, adding cinnamon and ginger, digesting for a week, and filtering, are almost always employed. In doses of from ten to thirty minims, properly diluted, these preparations exert a strong astringent power, and are serviceable in all forms of passive hemorrhages, and in checking inordinate discharges when they arise from debility. In ordinary diarrhoea, and even in the premonitory diarrhoea of cholera, dilute sulphuric acid is of great use. In painter's colic it is given in order to convert any lead that is absorbed into an insoluble sulphate, which is inert. Sulphuric acid lemonade is also used as a prophylactic against the disease. As this acid exerts a deleterious action on the teeth, it should be directed to suck it through a quill. In some cases it is prescribed not so much for its specific as for its solvent power; with this object it is usually prescribed with quinia. The strong acid is used in surgery as a caustic. In cases of *poisoning* with this acid the most prominent features are, burning pain extending from the mouth to the stomach, intense pain in the bowels, vomiting, great prostration, coldness of the surface, and fetor of the breath. The mucous membrane of the parts injured by the acid is at first converted into a white slough, which soon becomes black, and the patient usually dies from exhaustion within twenty-four hours. The best antidotes are the alkaline bicarbonates, or carbonate of magnesia. If the primary symptoms be conquered the patient often dies subsequently from stricture of the œsophagus.

Sulphuric Acid Manufacture.—There are two distinct processes by which sulphuric acid is at present prepared on a large scale—viz., by the distillation of green sulphate of iron—the original process of Valentine; and by the oxidation of sulphurous acid through the agency of nitrous acid and hyponitric acid. The first process is chiefly employed at Nordhausen, in Prussia, and is thus described by Fownes: "The sulphate of iron, derived from the oxidation of iron pyrites, is deprived by heat of the greater part of its water of crystallization, and subjected to a high heat in earthen retorts, to which receivers are added as soon as the acid begins to distill over. A part gets decomposed by the very high temperature; the remainder is driven off in vapor, which is condensed by the cold vessel containing a very small quantity of water or common sulphuric acid. The product is a brown oily liquid of about 1.89 specific gravity, fuming in the air, and very corrosive. It is chiefly used for the purpose of dissolving indigo."

The second method is that universally followed in Great Britain, the germs of which were likewise discovered by Valentine. He observed that when the fumes of burning sulphur and niter were collected under a bell jar, slightly moistened with water, a small quantity of liquid was deposited. This liquid, which was simply sulphuric acid, on being concentrated from its solution by boiling, was long sold as oil of sulphur *per campanum* at prices as high as 2s. 6d. per ounce.

About the year 1740, the French chemists Lefevre and Lemery suggested that, by the use of niter along with the sulphur, the operation might be conducted in close vessels, and a much greater quantity of acid might be produced. This idea was acted on in England by a Dr. Ward, who established works at Twickenham and Richmond, conducting his manufacture by burning the mixed sulphur and niter in large stoppered glass receivers, into each of which a small quantity of water was first introduced. The substitution, by Dr. Roebuck of Birmingham, of lead chambers in place of glass vessels, may be regarded as essentially the establishment of the process of manufacture followed at the present day. Dr. Roebuck established his first works at Prestonpans in 1749.

The first stage in the manufacture of sulphuric acid is the preparation of sulphurous acid by the burning of sulphur or of iron pyrites. Previous to the year 1838, Sicilian sulphur was almost exclusively used in the manufacture, but in that year the very ill-advised establishment of a monopoly of the sulphur trade by the Sicilian government, and its consequent increase in price, diverted the minds of manufacturers to the employment of iron pyrites (sulphide of iron), the use of which, as a source of sulphurous acid, was already not unknown. The monopoly was quickly abolished, on the representations of the English government, but not until it was demonstrated that the world was independent of Sicily both for sulphuric acid and sulphur. Iron pyrites is now much more used than sulphur, and the only hindrance to its universal adoption

is the presence of foreign matter in the pyrites, the most deleterious being arsenical compounds; and it has hitherto been found impracticable to free the sulphuric acid wholly from the arsenious acid which consequently accompanies it. This renders the acid prepared from pyrites inapplicable for many purposes.

When sulphur is the material used for producing the sulphurous acid, it is burned in an oven or "burner" (A) of brick-work, having a sole or bottom of iron, termed the "burner-plate." Under this a small fire is at first lighted, which is allowed to go out after the sulphur has ignited. A little above the sulphur, a small pot, called the niter pot, *n*, is either placed on a stand or hung from the roof, filled with a quantity of either nitrate of soda or nitrate of potash, with sulphuric acid sufficient for its decomposition—8 or 10 lbs. of the niter, with 5 or 6 lbs. of sulphuric acid, being allowed for every cwt. of sulphur. The decomposition of the niter by the action of heated sulphuric acid furnishes nitric acid fumes, which go over into the chamber along with the sulphurous acid. The sulphurous acid readily abstracts from the nitric acid the additional equivalent of oxygen required for its conversion into sulphuric acid, reducing the nitrous compound from nitric acid, N_2O_5 , to nitrogen dioxide, N_2O_2 ; the reaction being thus: $3SO_2 + N_2O_5 = 3SO_3 + N_2O_2$. Nitrogen dioxide in its turn quickly converts itself into nitrogen tetroxide, N_2O_4 , by the abstraction of two additional equivalents of oxygen from the air that is constantly entering the chamber through the burners. Again, in the presence of moisture, which is supplied by a jet of steam from the boiler C, sulphurous acid readily deprives the nitrogen tetroxide of two equivalents of oxygen, and thus forms two more volumes of sulphuric acid, and again liberates nitrogen dioxide; which is ready once more to seize upon the oxygen of the air, and would continue so acting and reacting *ad infinitum*.

Manufacture of Sulphuric Acid:

A, sulphur-burner, or furnace; B, lead chamber, shown in section at B'; C, steam boiler; D, leaden pan; E, coke tower; S, steam-pipe; *n*, niter pot.

tum, were it not carried forward and out by the chimney provided for the escape of the freed nitrogen.

The chamber is an immense box or room of lead, bound together with a strong framework of timber, and generally raised on arches several feet above the ground. Chambers vary in size from 60 to 140 ft. in length, and from 20 to 40 ft. in width and height. Curtains of lead proceeding alternately from the bottom to near the top, and *vice versa*, are very frequently used; they serve to retard the progress of the gases, and thus insure the transformations desired. The floor of the chamber is covered with water, into which the sulphuric acid falls as it is formed: and when this solution attains a certain strength, it is tapped off for concentration. When the gases reach the chimney, on account of the reactions of the nitrous compounds already explained, a large amount of nitrous acid would not only be wasted, but would also be deleterious to the neighborhood, were steps for its recovery not adopted. This recovery is usually effected by means of a tower filled with coke, E, down which a constant stream of strong sulphuric acid trickles, the acid absorbing the nitrous fumes in their way upward. Instead of a single chamber, curtained off or not as the case may be, sometimes three or five distinct chambers, connected by pipes, are employed, those communicating directly with the burners being termed working chambers, and the others receiving chambers, the last either acting as or communicating with a condenser or chimney. In France and Germany, the apparatus employed is generally of a more complicated nature, but in principle the operations are identical.

When iron pyrites is used as the source of sulphurous acid, a furnace somewhat on the principle of the ordinary lime-kiln is required. The pyrites is broken into pieces like nuts, washed, and spread in layers on plates heated to redness, and frequently stirred; or a quantity of coke is introduced with the first charge; and the heat evolved by the burning sulphur is thereafter sufficient fuel for the fresh charges. The exhausted ore is frequently sufficiently rich in copper for its extraction; indeed, when there is not

more than $2\frac{1}{2}$ per cent of that metal present in pyrites, it is now recovered, and this has led to the establishment of copper smelting works in connection with great chemical works near Newcastle and Manchester. The use of pyrites necessitates a chamber of comparatively larger size for the production of a given amount than is required when sulphur is used. The increased labor, with the greater quantity of niter wasted, and other circumstances, tend to make the cost of acid from both sources nearly equal.

In consequence of strong sulphuric acid absorbing both sulphurous acid and nitrous acid, the acid requires to be drained off from the chamber while the solution is comparatively weak, at which strength, viz., of a specific gravity of about 1.55, it is used for some purposes in the arts, under the name of "chamber acid." This is concentrated by evaporating, in lead pans, D, till it reaches the specific gravity of 1.71, then boiling in a platinum retort, on which strong acid does not act, even at high heat, or in large flint-glass retorts. Platinum retorts are extremely expensive; one to hold 80 gallons costing nearly \$4500. Large glass retorts which were used before the introduction of the platinum retorts, are again coming into favor with manufacturers. The only objection to their use is the great expense arising from frequent breakages, and consequent loss of both acid and retort.

The manufacture of sulphuric acid is a very extensive industry; immense quantities of it being consumed in the manufacture of soda, in that of bleaching-powder, in calico printing and dyeing, and, in fact, in most chemical operations both in the manufactory and the laboratory. In South Lancashire alone upward of 700 tons of concentrated acid are produced weekly. A process of purification is required for the acid in several of its minor applications; but for general purposes, it is sufficiently pure as supplied by the works. See Lunge's *Manufacture of S. A. and the Alkalies* (1879-81).

SULPHURIC ANHYDRIDE, **SULPHUR TRIOXIDE**, also known as **ANHYDROUS SULPHURIC ACID**, is represented by the formula SO_3 . It forms colorless transparent prisms; its melting-point is 60.8°F. (16°C.) and its boiling-point 114.8°F. (46°C.). The specific gravity of the liquid is 1.97 at 68°F. (20°C.). It unites with moisture when exposed to the air, and gives off dense white fumes. When thrown into water, the heat emitted is so great that it hisses as red-hot iron would do; and the solution has all the properties of ordinary sulphuric acid. It may be obtained by the distillation of fuming Nordhausen acid, when white fumes pass over in the cooled receiver, and solidify into a white silky-looking fibrous mass. It may be also obtained by the distillation of acid sulphate of soda, NaHSO_4 , after it has been deprived of one molecule of water. It combines with sulphur, iodine, and hydrochloric acid; but both it and its compounds are of chemical interest rather than practical value. See **CHEMISTRY**. A sulphuric anhydride containing upwards of 80 per cent. of SO_3 , the remainder being H_2SO_4 , is now made on a large scale and sold under the name of *crystallizable sulphuric acid*. It is used for the production of certain artificial dyestuffs, such as alizarin, soluble indigo, etc.

SULPHURIC ETHER is a term commonly but improperly applied to ethylic, vinic, or ordinary ether (q.v.). True *sulphuric ether*, known also as *sulphate of ethyl*, $(\text{C}_2\text{H}_5)_2\text{SO}_4$, is an oily liquid, of burning taste and ethereal odor, resembling that of peppermint, of specific gravity 1.183 (while that of ordinary pure ether is 0.720), and almost incapable of being distilled without decomposition, as at a temperature of about 406.4°F. (208°C.) it resolves into alcohol, sulphurous acid, and olefiant gas.

In the article **ETHER**, reference is made to the anæsthetic properties of that compound. Dr. Richardson has discovered that local insensibility may be readily induced by the application to the skin of the finely divided spray of perfectly pure rectified ether of specific gravity 0.723. The skin blanches in from half a minute to two minutes; and by following the knife with the spray, more than merely superficial incisions may be rendered painless. It has been successfully employed in amputations of fingers and toes, removal of tumors, opening of abscesses, removal of teeth, etc.

SULPHUROUS ACID some years ago became one of the most popular articles in our pharmacopœia. This sudden popularity was mainly due to the researches of a Scottish provincial physician, Dr. Dewar, of Kirkcaldy, who, from beginning his experiments on cattle, during the period of the cattle plague of 1866, extended them to other animals and to man, and obtained remarkably satisfactory results (see *Medical Times and Gazette* for 1867, vol. i., pp. 492, 548). There is, of course, nothing new in applying sulphur-fumes—which in reality are composed of sulphurous acid gas—as a disinfectant. The classical scholar will recollect that Ulysses employed them to remove the unpleasant smell arising from the dead bodies of Penelope's murdered lovers. "Bring brimstone, the relief of evils," he exclaims, "and bring me fire that I may sulphurize the house."—Hom. *Od.* xx. 481, 482. It is also recorded by Ovid (*Fasti*, iv. 735) and other writers that the shepherds of Italy yearly purified their flocks and herds with "the blue smoke of burning sulphur." Professor Graham's remark, that of gaseous disinfectants, sulphurous acid (obtained by burning sulphur) is preferable on theoretical grounds to chlorine, and that no agent checks so effectually the first development of animal and vegetable life, may be said to contain all that was known with regard to the medicinal value of this gas, till Mr. Dewar began his investigations. In his experiments in connection with the cattle-plague he found that the most safe and convenient apparatus consists of a chafer two-thirds full of *red cinders*, a crucible inserted in the cinders, and

a piece of sulphur-stick. A piece of sulphur as large as a man's thumb will burn for nearly twenty minutes, and will suffice for a cowhouse containing six animals; and it appears undoubted that if there be due ventilation, this process may be performed four times a day for at least four months with positive advantage to the animals. When this system had been efficiently carried out—and it has been largely tried by his friends—no case of illness, not to say of death, occurred. In Mr. Crookes's report *On the Application of Disinfectants in arresting the Spread of the Cattle-plague*, that able chemist observed that "the value of sulphurous acid in arresting the progress of the cattle-plague has been proved beyond a doubt by the experiments of Dr. Dewar, and my own results entirely confirm his." His experiments in relation to the cattle-plague led Dr. Dewar to the further discovery of the value of sulphur fumigation in other departments of veterinary medicine. Peripneumonia, ringworm, mange, are among the diseases which rapidly disappear under its influence; and in the sudden undefined illnesses known in Scotland as "drows" and "towts," to which most of our domestic animals are liable, sulphurous fumigation, if applied at the outset, rarely fails to cut short the attack.

In medical practice there are three different forms, independently of the sulphites, in which sulphurous acid may be employed—viz.: (1) As the sulphurous acid of the British Pharmacopœia, which contains 9.2 per cent by weight, or about twenty times the volume of sulphurous acid gas dissolved in water; (2) in the form of spray, which escapes from the preceding compound under the action of an apparatus called a spray-producer; and (3) as a gas evolved by sprinkling at intervals small quantities of "flowers of sulphur" on red-hot cinders placed on a common shovel, resting on a stool in the middle of the room, or by burning bisulphide of carbon (*Lancet* for 1876, vol. ii, pp. 712, 811). A mixture of equal parts of sulphurous acid and water has been recommended in all cases of "breaches of the skin," as primary wounds (whether resulting from injuries or surgical operations), in ulcers, burns, bed-sores, chapped hands, chilblains, saddle-sores (whether of man or beast), sore nipples, and in cases of bruises, such as black eye, etc. Moreover, in erysipelas, its soothing properties, if diluted with two or three parts of water, are very striking. According to Dr. Dewar, the feverish irritability of young children is speedily relieved by dropping from time to time a few minims (5 to 30, according to age) of the acid on a few folds of muslin fastened on the breast: here, however, the action is not local, but is due to the evolution of the gas which is inhaled. Amongst the cases in which the acid is serviceable when applied in the form of spray or inhaled as gas, are asthma, bronchitis, catarrh, croup, diphtheria, facial neuralgia, laryngeal affections, phthisis (at all events as a palliative), scarlatina, and typhoid. Dr. Dewar ascribes the healing action of sulphurous acid to its power of destroying fungi. That the acid has this power, we freely admit, but we cannot so readily admit the correctness of his view that all the diseases in which he has found it serviceable (including piles and chilblains) are dependent on fungous growths. Dr. Dewar reports a case of severe sciatica, in which immediate and perfect relief was afforded by the injection of an ounce of sulphurous acid in a breakfast-cupful of gruel into the rectum. There is one affection of this class, to which Dr. Dewar does not refer, in which it has been prescribed with advantage—viz., the form of gastric disorder in which *sarcina* (q.v.) *ventriculi* occurs in the vomited matter, the dose being half a dram, largely diluted with water.

None of the *sulphites* or *hyposulphites* have as yet been introduced into the Pharmacopœia. We notice them here because their action is supposed to depend upon the liberation of sulphurous or hypo-sulphurous acid when the salt comes in contact with the acid juices of the stomach. It is mainly to Dr. Polli that we are indebted for the introduction of the sulphites and hyposulphites of the alkalies and alkaline earths (soda, potash, and magnesia) into medicine. From the year 1857 onwards he for several years devoted almost all his time to the study of these agents. His labors are briefly summed up as follows by Dr. Sanson in an excellent memoir on "The Germs of Cholera, and the Means of their Destruction," published Jan. 22, 1868, in the *Medical Press and Circular*: "It was found that animals could, without any apparent ill effects, swallow and absorb large doses of the sulphites. It was then observed that when the animals were killed, they long resisted the putrefactive process. Another series of experiments—and in this series 300 dogs were the basis of the deductions—showed that the sulphites exerted a prophylactic and curative power when septic poisons were introduced into the economy. Then, as regards the human subject, it was found that the stomach would tolerate large doses of the sulphites of soda or magnesia. They were tried in the various eruptive fevers, intermittent, diphtheria, typhus, typhoid, cholera, and choleraic diarrhœa, pyæmia, puerperal fever, dissection wounds, malarial infection, etc. The records of cases treated in this way show an extraordinary amount of success." In a paper published by Dr. Polli himself in *The British Medical Journal* for Nov. 16, 1867, he states that since the promulgation, in 1861, of his views regarding the therapeutic value of the sulphites, no less than 158 papers on the subject have appeared; and with the exception of five or six containing certain criticisms on his labors, "all the remainder confirm, in the strongest terms, by many hundreds of detailed observations, the value of these remedies." A scruple of the salt dissolved in a wine-glassful of water flavored with tincture of orange-peel is the average dose, and it should be taken every four hours; and in some cases, as in typhoid, a grain of quinine may be advantageously added to each dose. M. de

Ricci (*Dublin Quarterly Journal*, Nov., 1866) prefers the sulphite of magnesia on the grounds that it is less unpalatable, and contains a larger proportional quantity of acid, than the soda salt. The remarkable results obtained by Dr. Dewar have not been paralleled in the experience of other physicians, but the acid is recognized as a valuable remedy, in many diseases, especially those caused by parasites.

In consequence of the powerful antiseptic properties of sulphurous acid, either in the form of gas or gaseous solution in water, and of the sulphites, these substances have been employed for the purpose of preserving meat from putrefaction. A joint of meat or a fowl submitted to a daily sulphur fumigation may be kept fit for use for many weeks. The bisulphite of lime has been found to be the most applicable of the various compounds of this class as a preservative; and Messrs. Medlock and Bailey have patented a method of preserving meat by means of a preparation of this salt. In hot weather a few drops of a strong solution of this salt will serve to keep fresh a pint of soup, jelly, milk, etc. Dr. Dewar patented a method of preserving meats by sulphurous acid, or some of its compounds; but as yet the process has not come into extensive use.

SULPICIANs, a society of priests formed in 1641 by Jean Jacques Olier for the purpose of educating priests, and deriving its name from the parish of St. Sulpice in Paris, of which he was pastor a year later. When their number had increased, a part assisted the pastor, and others took charge of a seminary. The priests of this society have conducted seminaries in France and some in America. Their institutions in France were suspended in the revolution, but in 1816 restored. Some of their members, as Olier, J. A. Emery, and Carrière have been distinguished as theologians.

SULTAN, or **SULTAUN**, an Arabic word, signifying "mighty man," and evidently closely connected with the Hebrew word *shalal*, to rule, is in the east an ordinary title of Mohammedan princes, and also used in private life as a title of courtesy for people of high rank. It is given, *par excellence*, to the ruler of Turkey, who assumes the title sultan-es-selatin, or sultan of sultans. It is also applied to his mother and daughters; the word in Turkish having no grammatical gender, and corresponding also to our princess. The wife of the sultan is not now entitled to the epithet sultan or sultana.

SULU ISLANDS, an archipelago of above 60 small and rocky, yet fruitful islands in the Mindoro sea, between the Philippines and Borneo (q. v.). Cagayan Sulu, the chief of the islands, 36 m. long and 12 broad, contains the town of Soong, the residence of the sultan of the group. Pop. '87, 104,015. See **PHILIPPINE ISLANDS**.

SUMACH, *Rhus*, a genus of small trees and shrubs, of the natural order *anacardiaceæ*; having small inconspicuous flowers in panicles or in corymbs; a 5-parted calyx, 5 petals, springing from beneath a large orbicular disk; 5 stamens; a 1-celled germen with 3 stigmas; the fruit a small, nearly dry drupe, with bony *putamen*. The species are numerous, diffused over almost all parts of the world, except its coldest regions and Australia; and some of them, on account of peculiar principles which they contain, are of importance in the arts and in medicine; some are remarkable for their poisonous properties.—**VENETIAN SUMACH** (*R. cotinus*), known also as wig sumach or wig tree, is a native of the s. of Europe and w. of Asia, and is often planted in Britain as an ornamental shrub. It has simple leaves, and hairy corymbs of fruit, which have a sort of resemblance to periwigs. The wood dyes yellow; and, with the addition of other substances, green and brown, and is known in trade by the name of *young fustic*. It is largely imported into Britain. The bark is sometimes used as a substitute for Peruvian bark. The leaves are astringent, and are used for dyeing Turkey red. The root is also used in dyeing, and the whole plant is used in Italy for tanning, and is there called *scotino*. The seed resembles the almond in flavor.—The very acid fruit of the **ELM-LEAVED SUMACH** (*R. coriaria*)—a native of the countries around the Mediterranean, with pinnate leaves, not unfrequent in British shrubberies—has been used from the earliest times, as it still is by the Turks and Persians, as a condiment with different kinds of food. Both the seeds and the leaves are used medicinally, in the s. of Europe and the e. as tonic and cooling. This species is also extensively used for tanning, particularly in Turkey and in Spain. The leaves and twigs are used for dyeing black, the roots and fruit for dyeing red, and the bark for dyeing yellow.—Similar to this in its properties and uses is the **VIRGINIAN SUMACH**, or **STAG'S-HORN SUMACH** (*R. typhina*), a native of almost all parts of North America, and common in British shrubberies, which has the branches curiously crooked, and covered, when young, with a soft velvety down. It has pinnate leaves, with numerous leaflets.—The **SMOOTH-LEAVED SUMACH** (*R. glabra*), a very similar species, also North American, has very acid leaves, which are eaten by children, and are used in domestic economy and in medicine on account of the malic acid which they contain. The bloom of the fruit is also very acid. This species is sometimes troublesome in North America, overrunning ground as a weed.—Of the acrid and poisonous species, the most important is the **POISON OAK** (*R. toxicodendron*) of North America, a shrub from 1 to 3 ft. high, with leaves of 3 leaflets, and a milky juice, which becomes black on exposure to air. The leaves are used in medicine in cases of paralysis, amaurosis, and other nervous affections, as a stimulant of the nervous system, also in chronic rheumatism and obstinate eruptions; but are efficacious only when fresh, as the poisonous substance is volatile. Similar to this in properties are the **POISON IVY**, or **POISON VINE** (*R. radicans*), the **POISON ALDER**, **POISON SUMACH**, or **SWAMP SUMACH** (*R. venenata*), also known as dog-

wood, and other North American species, the juice of which is very acrid, and even the emanations are injurious to some persons, who from remaining a short time near these plants, or from handling them, experience swelling of the whole body, with subsequent inflammation of the skin, pustules, and violent itching, while it is remarkable that others appear quite unsusceptible of their influence.—The VARNISH SUMACH or JAPAN VARNISH TREE (*R. verniceifera*), a native of Japan and Nepal, yields a varnish much used in Japan for lacquer-work. This varnish is the juice which flows from wounds in the tree, and which becomes thick and black by exposure to the air, but is still so transparent that the finest veins of wood varnished with it may be seen through it. It is sometimes mixed with coloring matters, sometimes with gold-leaf finely ground. The expressed oil of the seeds becomes as hard as tallow, and is used for candles.

The name TANNERS' SUMACH is given to *coriaria myrtifolia*, a shrub of the s. of Europe, of the natural order *Ulmaceæ*. The leaves are astringent, and are used for tanning, and for dyeing black.

SUMATRA (called by the Arabians *Srimat* or *Srimata*, "the happy," whence its present name), the most westerly of the Sunda islands, lies s. of the Malay peninsula, from which it is separated by the strait of Malacca. Lat. between $5^{\circ} 45' \text{ n.}$ and $5^{\circ} 50' \text{ south.}$ It is 1040 m. long and 266 m. in extreme breadth; area, 168,000 sq. m.; population estimated at about 4,000,000. The following table, taken from the *Statesman's Year-book* for 1897, gives the area of each district into which the island is divided and the estimated population at the end of 1894.

| | Area in Sq. Miles. | Population, 1894. |
|----------------------|--------------------|-------------------|
| West Coast..... | 31,649 | 1,275,585 |
| East Coast..... | 35,312 | 304,990 |
| Bencoolen..... | 9,399 | 160,508 |
| Lanpongs..... | 11,284 | 135,194 |
| Palembang..... | 53,497 | 694,613 |
| Acheen or Atjeh..... | 20,471 | 447,684 |
| Total..... | 161,612 | 3,018,574 |

These estimates are only approximate. Another estimate places the number of inhabitants of the districts wholly under Dutch control at 3,090,301. The others, numbering about 1,000,000, still retain their independence in spite of the efforts of the Dutch to enforce their rule over them. The independent natives reside chiefly in the so-called kingdom of Acheen, where the Dutch for many years have encountered serious opposition. The Europeans in 1891 numbered 4,953, the Chinese, 95,000, and the Arabs, 2,854. The chief cities are Padang and Bencoolen on the western coast and Palembang on the eastern coast.

Physical Features.—The Barisan mountains run throughout its entire length, varying in altitude from 1550 ft. in the s.w. to 6,000 under the equator. Lofty cones, of which about 20 are volcanoes, attain to from 6,000 to upward of 10,000 feet. Another series of mountains runs parallel with the Barisan, lofty plateaus of great extent linking them together at various points. On the w. coast, a few m. of low land lie between the mountains and the sea, in some parts spurs reaching the shore in beetling cliffs. Wide alluvial plains, covered with dense jungle and forest, through which the rivers run sluggishly, forming deltas at their mouths, stretch along the n.e. coast; while the tidal action is eating into the w. coast, new ground is forming on the east. Extensive valleys lie between the mountain chains. Several beautiful lakes are scattered over the interior. The largest is lake Singkarak or Samawang, in upper Padang, 17 m. long and 6 broad.

The mountain systems are of trachyte, granite, limestone, red sandstone, and a widespread conglomerate composed of granitic and quartzose particles, the hollows in many places being filled with lava. Sienite, porphyry, serpentine, jasper, basalt, and tufa occur. Tertiary deposits are found in the valleys, and in some parts of the coasts a rich vegetable mold rests on beds of red and gray clay, or on coralline limestone. Potter's clays are met with, and gold is widely diffused. Coal, iron ore, copper, sulphur, lead, silver, saltpetre, alum, naphtha, etc., abound.

Rivers.—Sumatra has many rivers, the most important being the Tulang-Bawang; the Mûsi, or river of Palembang; the Djambi, Indragiri, and Siak, on the e.; the Singkel, Tabûjong, Indrapûra, Moko-Moko, Bencoolen, and Padang Gûtjie on the west. The capes and bays are numerous, the bay of Tapanûli being capable of containing a large fleet. A chain of islands lies parallel to Sumatra in the Indian sea. The most important are—Babi or Si Malu, Nias (q. v.), the Batû islands, North Pora, Coco island, South Pora, North Pagei, and South Pagei. To the s.e. lies Banca, rich in tin, producing also iron, lead, silver, copper, arsenic, and amber.

Climate.—The climate of Sumatra is moderately healthy, especially on the e. coast. In Tapanûli, however, are large marshes, inducing intermittent and typhoidal fevers, dysentery, and other diseases. A slight increase of temperature takes place from October to March, the minimum being in May. The monsoons are irregular, and rain falls during all the months, though the quantity in October and December is double that in February and June.

Flora.—Sumatra has many fine species of timber trees—as the djati (*tectona grandis*), the maris, a hard and heavy wood, ebony, iron-wood, etc. The magnificent *dryobalanops camphora*, and other resin-producing trees, are abundant. Several species of fig, the *urceola elastica*, from which caoutchouc is obtained, and the gutta-percha tree (*isonandra gutta*), are numerous. In the villages the bombax, or silk-cotton tree, forms a shady resting-place at noon. The lovely *cinnamomum cassia*, the *melaleuca leucadendron*, which yields the medicinal cajuput oil, the satin-wood (*chloroxylon swietenia*), the gigantic reed (*calamus draco*), from the ripe fruit of which the dragon-blood gum exudes, and a great variety of palms, form part of the botanical wealth of the island. Flowering plants and shrubs are numerous, and countless parasites garland the forest trees with flowers of every hue. The most curious of these is the *rafflesia* (q.v.), which, clinging to the bark of large trees, spreads out the largest known flower, with a calyx 3 ft. in diameter and 9 in. deep, and capable of containing 2 gallons of fluid.

The fruits are richer in flavor than those of Java. Among these are the guava, citron, oranges, lemon, durian, mango, bread-fruit, cocoa-nut, pomegranate, water-melons, pine-apples, and the highly-prized mangosteen, or berry of *garcinia mangostana*. Cacao, cotton, maize, indigo, tobacco, gambier, and more especially rice, millet, pepper, and coffee, are cultivated.

Fauna.—The elephant, single and double horned rhinoceros, tiger, leopard, black bear, and tiger-cat, wild-swine, tapirs, antelopes, deer, monkeys (including the ourang-outang), ant-eaters, many kinds of bat, etc., abound. Buffaloes, cows, goats, horses, sheep, and swine are kept by the natives. The peacock and the pheasants of Sumatra are of rare beauty. Hippopotami and crocodiles frequent the rivers, which have many kinds of fish, including a species of salmon.

People.—The natives are chiefly Malays who profess Mohammedanism. In appearance, manners, and customs, however, the inhabitants of Acheen and the Lampongs differ widely from those of other parts. The Acheenese are tall, well-made, active, and intelligent, but cunning, proud, treacherous, and blood-thirsty. They live simply, but are slaves to opium. The Lampongs are of middle stature, well-formed, of pleasant exterior, mild, but uncivilized and lazy. Caste prevails, and they follow the usages of their fathers, Mohammedanism being imperfectly known and practiced. Polygamy obtains, the wives being bought from their relatives. The houses are on posts of iron-wood, several families living under the same roof. In other parts of Sumatra the usual Malay type is found. The Kūbūs, in the n.w. of Palembang, are probably the remains of the aborigines, a harmless race who live chiefly by the chase and fishing. Theft and murder are scarcely known among them. They believe in an after spirit-life.

Trade and Produce.—There is a considerable trade in indigo, cotton, tobacco, maize, and rice. Teak-wood occurs in the forests, and coffee is raised in some parts of the island. The chief occupations are agriculture and shipping. In earlier times piracy was practiced extensively by the inhabitants. The principal industries are the weaving of cotton cloth and the working of gold. Tobacco has become an important product and is exported in considerable quantities, being highly valued for wrapping purposes. Much of it finds its way to the United States and at one time it was estimated that one-third of the entire tobacco crop was taken by the latter country. The influx of Sumatran tobacco was so great as to occasion alarm to the United States seed-leaf growers, and a very high duty was levied upon it in the McKinley tariff, not, however, with the result of preventing the importation, which in two years, became as extensive as it ever had been. The importance of the Sumatran tobacco as an article of commerce was pointed out in 1862 to a trading company in Batavia, and from that time on, the trade was rapidly developed. The island contains a fair supply of minerals, but its resources in this respect have not been developed. The chief minerals are gold, copper, iron, lead, coal, and petroleum.

History.—Marco Polo visited Sumatra in the 13th c., Alvaro Talezo in 1506, and Siquera in 1509, the Portuguese then entering into trading relations with the natives. About 90 years later the Dutch under Houtman reached the island, and on a second visit he was treacherously murdered at Acheen. In 1601 two ships from Zealand, with the Netherlands commissioners, Gen. De Roi and Laurens Bikker, arrived; were favorably received by the king, obtained a full cargo, and returned with two Acheenese ambassadors. Later, the Dutch drove the Portuguese from their factory at Pulū Tjinko, to the s. of Padang; and in 1666 the latter place became the seat of the Netherlands power on the w. coast. In 1795 Padang was taken by the British, and retained till 1819. A few years after, Bencoolen was also given up to the Dutch, and the southern division of the island soon fell under the same rule. Various rebellions against the Netherlands dominion have since arisen, with the uniform result of extending the power of the Dutch toward the interior and the north. The appalling eruption of 1883 at the volcanic island of Krakatoa, between Sumatra and Java, raised a vast sea wave which swept destructively the southern shore of S., and raised a new line of volcanic cones in the straits of Sunday. For an account of the wars between the Dutch and the natives of Acheen, see the article NETHERLANDS. See also *Flora van Nederlandsch-Indië*, by F. A. W. Miquel (Amst. and Leip., 1855); *The Malay Archipelago*, by A. R. Wallace (1869); *Australasia*, by A. R. Wallace (1880); and for a map of the island, Dornseiffen and De Geest, *Sumatra, Bangka en der Rioult-Lingga-Archipel* (1892).

SUMBAWA, one of the chain of islands to the e. of Java, lies between 8° 4' and 9° 2' s. lat., and 116° 50' to 119° 15' e. long., is now divided into the kingdoms of Sumbawa,

Bima, Dampo, Mangherai, and Sangar, governed by separate sovereigns, and owing allegiance to the Netherlands. The seat of the Dutch resident governor is at Bima. Area, 5,838 sq. miles. Pop. nearly 100,000. The island is mountainous, but except the volcano Tambora, which is 9,522 ft., the elevation does not exceed 5,660. The most valuable timber-tree is the djati (*tectona grandis*, or Indian teak), and the tamarind is so abundant as to be little valued. Rice is extensively grown. Sapan-wood is contracted for with the princes, by the Netherlands colonial government. Pop. about 150,000.

In 1815 an eruption of Tambora depopulated the kingdoms of Tambora and Papekat, 42,000 lives being lost, and great damage done to the whole island by the ashes. Another took place in 1836, and one of Gunong Api, in Bima, in 1860, but with little loss.

SUM'BUL (see MUSK PLANT) has been extensively employed for some years past, both in this country and in Gt. Britain in the treatment of epilepsy, hysteria, and other diseases of the nervous system. It has a musk-like odor, and an aromatic and somewhat bitter taste. It may be given in the form of infusion, tincture, or resin.

SUMMARY DILIGENCE, in the practice of the law of Scotland, means issuing execution without the formality of an action, as a creditor enforcing payment of a bill of exchange or of a bond.

SUMMER, a horizontal beam, called also breast summer.

SUMMER DUCK, or WOOD DUCK, *Dendronessa sponsa*, or *aix sponsa*, a very beautiful species of duck, of the section having the hind-toe destitute of membrane, a native of North America. It is found during the breeding season in almost all parts of the United States, and as far n. as Nova Scotia, migrating southward in winter, when it abounds in Texas and Mexico, but some remain during winter even in Massachusetts. It has been found capable of domestication.—Very similar to it is the MANDARIN DUCK (*dendronessa* or *aix galericulata*), a Chinese species. Both of these species have the power of perching on trees. The summer duck makes its nest in the hollow of a tree.

SUMMERFIELD, JOHN, 1798-1825; b. England; educated at the Fairfield Moravian seminary; was a clerk at 14 in a mercantile house in Liverpool, and fell into bad habits; went with the family to Dublin in 1813; joined the Wesleyans; became a preacher in the Irish conference, 1818; preached with eloquence and success in Ireland and England; came to America with his father, 1820, and joined the New York conference. In New York, Philadelphia, Baltimore, and Washington, his remarkable eloquence drew immense crowds from all denominations, classes, and professions. His health failing under his excessive labors he sailed for France in 1822; represented in Paris the American Bible society to the French Protestant Bible society; spent some time in England; returned to New York, 1824, and continued to travel and preach, though in feeble health. He aided in forming the American tract society. His *Sermons* and *Sketches of Sermons* were published, with a biography by John Holland.

SUMMER ISLANDS, a small archipelago of islets off the w. coast of Scotland, near the entrance of loch Broom, an inlet in the n.w. of the county of Ross. The islets are about 20 in number; and the largest of them, Tanera, 2 m. long, and 1 m. broad, has a pop. of 119.

SUMMERS, a co. in s. West Virginia, drained by the Greenbrier and Kanawha rivers and traversed by the Chesapeake and Ohio railroad; formed in 1871 from four other cos.; pop. '90, 13,117, chiefly of American birth, with colored. The surface is rough and hilly, fertile only in the bottom lands; corn, wheat, and cattle are the staples. Area, 400 sq. m. Co. seat, Hinton.

SUMMERS, THOMAS OSMOND, D.D., LL.D., b. England, 1812; came to America, 1830; joined the Methodist Episcopal church, 1832; received into the Baltimore conference, 1835; missionary to the republic of Texas, 1840, and was one of the nine preachers who formed the first Texas conference; became a member of the Alabama conference, 1844; was secretary of the conference at Louisville, Ky., where the Methodist Episcopal church, South, was organized. Dr. S. published *A Treatise on Baptism; A Treatise on Holiness; Sunday-school Teacher, or the Catechetical Office; Seasons, Months, and Days; Talks Pleasant and Profitable; The Golden Censer; Scripture Cathecism*, 2 vols.; *Questions on Genesis; Refutation of the Theological Works of Thomas Paine*. He was appointed in 1846 assistant editor of *The Southern Christian Advocate*; edited *The Sunday-school Visitor* for seven years, and *The Quarterly Review* of the Methodist Episcopal church, South, in 1858; was chairman of the committee appointed to prepare the new hymn book, and edited nearly all the publications of the Southern Methodist church. He d. 1882.

SUMMIT, a co. in central Colorado, crossed by the Rocky mountains; intersected by the Denver, Leadville, and Gunnison railroad; 690 sq. m.; pop. '90, 1906. There are large deposits of gold, iron, coal, lead, copper, and zinc. Co seat, Breckinridge.

SUMMIT, a co. in n.e. Ohio, drained by the head-waters of Tuscarawas river and the Cuyahoga; 391 sq. m.; pop. '90, 54,088, chiefly of American birth, with colored. It is intersected by the Ohio and Erie canal, here at its highest elevation, and by the Baltimore and Ohio, the Cleveland, Akron, and Columbus, the Erie, the Northern Ohio and Valley, and other railroads. Its surface is hilly, diversified by lakes, and contains the long narrow valley of the Cuyahoga, 300 ft. deep. The streams furnish extensive water-power; there is a good supply of timber; rich coal beds are mined; there are sandstone and fire clay. Large numbers of sheep and other stock are raised, and the

soil produces grain, and dairy products. The manufactures are important, embracing carriages, cooperage, lumber, leather, cutlery and edged tools, machinery, paper, iron castings, etc. Co. seat, Akron.

SUMMIT, a co. in n.e. Utah, bordering on Wyoming; crossed by the Wasatch mountains, whose plateau is 11,000 ft. above sea-level; 3062 sq. m.; pop. '90, 7733. The surface is covered with vast forests. It has large deposits of gold, silver, lead, and coal. Co. seat, Coalville.

SUMMONS, in American law, means generally a writ directed to a party to appear and answer some complaint before a court or judge. It is the first writ in an action at law; and a similar writ issues incidentally both in chancery and interlocutory matters. It is also the first step in proceedings before justices. In England it is also the first writ in an action.

SUMNER, a co. in s. Kansas, having the territorial line of Oklahoma for its s. boundary; 1188 sq. m.; pop. '90, 30,271, chiefly of American birth, with colored. It is drained by Arkansas river, Good river, and Cowskin and Slate creeks. The surface is level prairie, containing every element of fertility. Co. seat, Wellington.

SUMNER, a co. in n. Central Tennessee, adjoining Kentucky; drained by branches of the Big Barren and Cumberland, by which it is bounded s.; traversed by the Louisville and Nashville and the Chesapeake and Nashville railroads; 536 sq. m.; pop. '90, 23,668. The surface is heavily wooded and elsewhere fertile; tobacco, corn, wheat, oats, and pork are the staples. Co. seat, Gallatin.

SUMNER, CHARLES, statesman, oldest son of Charles Pinckney Sumner and Relief Jacobs Sumner, was born in Boston, Mass., Jan. 6, 1811. The Sumners, several of whom were Harvard graduates, were a prominent family in early Massachusetts history. One, Increase Sumner, was governor from 1797-99. Charles's father, a scholarly man, was a fine lawyer, and for many years sheriff of Suffolk Co. Josiah Quincy said of him: "He is the only sheriff, except Walter Scott, born on Parnassus." The Sumners were noted for both physical and intellectual vigor, and Charles was tall, broad-shouldered, and of commanding presence, and so remarkable was his memory that he was known as the best historical student of his time. He graduated from Harvard in 1830, studied law with Judge Story, and was admitted to the bar in 1834. The Judge formed a deep attachment for him, and appointed him Reporter of his court. While in this position, he published three volumes of Story's decisions, known as *Sumner's Reports*, which made him well known in England. He frequently supplied Story's place as lecturer at the law school, and was himself a lecturer there from 1835-37, and again in 1843. In 1837-40 he visited Europe, where he was the recipient of much flattering attention. On his return he, with J. C. Perkins, edited *Vesey's Reports*, with annotations, in twenty volumes. In 1845 he delivered the Fourth of July oration in Boston on *The True Grandeur of Nations*, of which Cobden said: "It is the noblest contribution ever made by any modern writer to the cause of peace." But it gave offense to the leaders of the Whig party, which was further deepened by the stand he took on the admission of Texas, and eventually led to his entire withdrawal from that party, and his association with the Free-Soilers. In 1846 he delivered another powerful speech on "Our Present Anti-Slavery Duties," which gave such offense to the circle in which he moved, as to almost crush him both socially and professionally. Although keenly sensitive to this change of public sentiment, he never for an instant wavered from his championship of the right as God gave him to see the right. In 1852 he presented a memorial against the Fugitive Slave Bill. The majority were determined he should not deliver a speech he was known to have prepared on the subject; but he watched his opportunity, and in August, being entitled to the floor, held it against all opposition for over four hours. His theme was "Freedom National, Slavery Sectional," and this phrase became a watchword of the party. In 1856 he made one of his ablest speeches on "The Crime against Kansas," some portions of which so incensed the southern members, that Preston S. Brooks (q.v.), of South Carolina, assaulted him, and the injuries proved so serious that he was abroad for medical treatment much of the time for four years. In 1859 he resumed his seat, and in 1860 became one of the most prominent leaders of the Republican party. His speeches, which were on all topics of national importance, were always powerful and had great influence with the public. Among these may be noticed the speech against the seizure of Mason and Slidell, on "Our Foreign Relations," on "The Case of the Florida," and his "Eulogy on President Lincoln." Later, he took an active part in all anti-slavery legislation, in reconstruction measures and in the impeachment of President Johnson, while his speech in reference to the Alabama Claims caused great indignation and much criticism among all his English friends. In 1869 he opposed the Santo Domingo treaty, which brought him in collision with the administration, and led ultimately to his separation from the Republican party, and his support of Horace Greeley for president in 1872. The last efforts of his life were his resolution that "the names of victories in the civil war should not be inscribed on regimental flags," and his Civil Rights bill, giving equal rights to white and black in every state in the Union, so far as personal rights under the law were concerned. It was thought he never recovered from the attack made on him by Mr. Brooks in 1856; and in 1874 this trouble returned to him in a serious malady of the chest, which proved fatal on March 11. Almost his last words were to Judge Hoar: "Take care of my Civil

Rights Bill." See Lester, *Life of Sumner*; *Orations and Speeches*; and *Complete Works*, a collection prepared by himself (twelve volumes, Boston, 1871-75).

SUMNER, EDWIN VOSE, 1797-1862; b. Boston; appointed to the army in 1819; served in the Black Hawk war on the Indian frontier, and through the Mexican war. He was dangerously wounded at Cerro Gordo, where he led the charge, and was brevetted colonel for his conduct at Molino del Rey, where he was in command of the cavalry. He was governor of New Mexico, 1851-53; led an expedition against the Cheyennes in 1857; and in 1861 succeeded Twiggs as brig. gen., and assumed command of the department of the Pacific. He was soon recalled to the e., and taking command of the 1st corps of the army of the Potomac, served through the peninsular campaign of 1862, in which he was twice wounded. The same year he became maj. gen. of volunteers, and took command of the 2d corps. He was at Fredericksburg, and early in the next year was ordered to take command of the department of the Missouri, but died on his way.

SUMNER, WILLIAM GRAHAM, born Paterson, N. J., 1840. He graduated at Yale coll. in 1863; 1863-66 studied in Germany and England; afterwards entered the ministry of the Prot. Epis. church, and was assist. minister of Calvary church, New York. In 1872 he was appointed prof. of political and social science in Yale coll. He is the author of *History of American Currency*, *Andrew Jackson as a Public Man*, and *Lectures on the History of Protection in the United States*, *The Financier and Finances of the American Revolution* (1891). He is a well known and ardent champion of free trade, and both as a college teacher and as a public lecturer on his favorite theme, he has drawn wide attention by the keenness of his argument, the clearness of his style, and the uncompromising quality of his statements.

SUMPTUARY LAWS (Lat. *sumtus*, expense), laws passed to prevent extravagance in banquets, dress, and private expenditure. They abound in ancient legislation. The Locrian legislator, Zaleucus, 450 B.C., ordained that no woman should appear in the streets attended by more than one maid-servant, unless she were drunk, or wear gold or embroidered apparel, unless she designed to act unchastely. At an early period in Roman history, the censors, to whom was intrusted the superintendence of public and private morality, punished with the *notatio censoria* all persons guilty of luxurious living; but as the love of luxury grew with the increase of wealth and foreign conquest, various legislative enactments were passed with the object of restraining it. The *lex Orchia*, 161 B.C., limited the number of guests to be present at a feast; the *lex Fannia*, 161 B.C., regulated the cost of entertainments, enacting that the utmost sum which should be expended on certain festivals was to be 100 asses, 30 asses on certain other festivals, and 10 asses on an ordinary entertainment, where also no other fowl than one hen was permitted to be served up, and that not fattened for the purpose. There were also the *lex Didia*, *Lucretia*, *Cornelia*, *Æmilia*, *Antia*, *Julia*, and others, most of them passed in consequence of the practical disregard of the similar laws that had preceded them; but they all seem to have been habitually transgressed in the later times of the republic.

Sumptuary laws were in great favor in the legislation of England from the time of Edward III. down to the reformation. Statute 10 Edward III., c. 3, narrates that "through the excessive and over-many costly meats which the people of this realm have used more than elsewhere, many mischiefs have happened; for the great men by these excesses have been sore grieved, and the lesser people, who only endeavor to imitate the great ones in such sorts of meat, are much impoverished, whereby they are not able to aid themselves, nor their liege lord, in time of need, as they ought, and many other evils have happened as well to their souls as their bodies;" and enacts that no man, of whatever condition or estate, shall be allowed more than two courses at dinner or supper, or more than two kinds of food in each course, except on the principal festivals of the year, when three courses at the utmost are to be allowed. All who did not enjoy a free estate of £100 per annum were prohibited from wearing furs, skins, or silk, and the use of foreign cloth was allowed to the royal family alone. Act 37 Edward III. declares that the outrageous and excessive apparel of divers people against their estate and degree is the destruction and impoverishment of the land, and prescribes the apparel of the various classes into which it distributes the people; it goes no higher than knights, but there are minute regulations for the clothing of women and children. This statute, however, was repealed the next year. In France there were sumptuary laws as old as Charlemagne, prohibiting or taxing the use of furs; but the first extensive attempt to restrict extravagance in dress was under Philip IV. By an edict of Charles VI. no one was allowed to exceed a soup and two dishes at dinner. Sumptuary laws continued to be introduced in England in the 16th, and in France as late as the 17th century. Scotland had also a similar class of statutes. The Scottish parliament attempted to regulate the dress of the ladies, to save the purses of the "puir gentlemen, their husbands and fathers." There was a prohibition against their coming to kirk or market with the face muffled in a veil; and statutes were passed against superfluous banqueting, and the inordinate use of foreign spices "brocht from the pairts beyond sea, and sauld at dear prices to monie folk that are very unablill to sustain that coaste." Neither in England, Scotland, nor France do these laws appear to have been practically observed to any great extent: in fact, the kings of France and England contributed far more, by their

love of pageantry, to excite a taste for luxury among their subjects than by their ordinances to repress it. Mr. Froude suggests that such statutes may have been regarded, at the time when they were issued, rather as authoritative declarations of what wise and good men considered right, than as laws to which obedience could be enforced. Enactments of this kind have long been considered to be opposed to the principles of political economy. Most of the English sumptuary laws were repealed by 1 James I., c. 25, but a few remained on the statute-book as late as 1856.

SUMTER, a co. in w. Alabama, adjoining Mississippi; bounded on the e. by the Tombigbee river, drained by Sucarnoochee creek and the Noxubee river; traversed by the Southern, the Alabama, Great Southern, and other railroads; about 970 sq. m.; pop. '90, 29,574, includ. colored. The surface is rolling and heavily wooded. The soil is fertile. The principal productions are corn, cotton, and live stock. Co. seat, Livingston.

SUMTER, a co. in c. Florida, 600 sq. m.; pop. '90, 5,363. The surface is level and partly swampy. Co. seat, Sumterville.

SUMTER, a co. in s.w. Ga., drained by the Flint river, its e. boundary, and by several creeks; traversed by the Georgia and Alabama, and the Central of Georgia railroads; area, 515 sq. m.; pop. '90, 22,107, chiefly of American birth, includ. colored. The soil is level and fertile; cotton, corn, and pork are the chief productions. Co. seat, Americus.

SUMTER, a co. in e. central S. C., drained by the Wateree and Black rivers and Lynch's creek; traversed by the Atlantic Coast Line railroad; about 870 sq. m.; pop. '90, 43,605, chiefly of American birth, includ. colored. Surface level and extensively covered with pine forest, the tar and turpentine from which are, with cotton, the main exports. Co. seat, Sumter.

SUMTER, FORT (originally spelled *Sumpter*, after Gen. Sumpter, in whose honor it was named), an American fort of the second class, built 1845-'55, in the form of a truncated pentagon 50 ft. high, on an artificial island, at the entrance of Charleston harbor, 2½ m. distant from Forts Moultrie and Pinckney, on either side. On the secession of South Carolina, Dec., 1860, Maj. Anderson, in command of the defenses of the harbor, was called upon to surrender them to the state authorities. Instead of doing this, he abandoned the other forts and occupied Fort Sumter, mounting 52 guns, with a garrison of 70 men and 30 or 40 workmen. This was considered an act of war by the confederates and their troops, who, under command of Gen. Beauregard, took possession of Forts Pinckney and Moultrie, and erected additional batteries. While the surrender of the fort was under consideration, a fleet was sent from New York for its relief. On its appearance off the harbor, the attack on the fort was opened by Gen. Beauregard, April 12, 1861, and it surrendered on the 13th. This event aroused the north, and began the war, which terminated in 1865. During the siege of Charleston this fort was battered by the heaviest artillery, until its walls were completely crushed and shattered. The flag-staff was shot away fifty times, and thousands of tons of iron projectiles were mingled with the débris of the fort; but the garrison constructed a still stronger fortress on its ruins, and held it for three years against assault and bombardment, until the operations of Gen. Sherman compelled its evacuation, and the United States flag was again raised, April 14, 1865; an event soon followed by the evacuation of Richmond, and the surrender of all the confederate armies.

SUMTER, THOMAS, 1734-1832, b. Va.; settled in South Carolina. He took part in the Cherokee war, and was prominent in the political movements which resulted in the revolution. He became col. of the 2nd regiment of riflemen in 1776, and remained in the state till the surrender of Charleston, when he enlisted a considerable force in North Carolina, and defeated a body of British and Tories. Soon afterwards he unsuccessfully attacked the post at Rocky Mount. Within a few days he defeated the Prince of Wales regiment at Hanging Rock and dispersed a large force of Tories. Routed in his turn by Tarleton at Fishing Creek, he recruited another force with which he beat Tarleton at Blackstocks, but was dangerously wounded. He was made brig. gen. of the S. C. militia, and was thanked by congress. In 1781 he enlisted 3 regiments of rangers and aided Marion and other generals. He sat in the convention which formed the federal constitution; was a member of congress, 1789-93 and 1797-1802, and was U. S. senator, 1801-09. He was U. S. minister to Brazil, 1809-11.

SUMY, a t. of Russia, in the government of Kharkov, and 90 m. n. w. of the town of that name, on the Psol. It is an important commercial center for the Ukraine, and has an extensive trade in horses, grain and sugar. Pop. '93, 22,764.

SUN, THE, the great luminary upon which not only our well-being but our very existence depends, has been from the earliest ages a source of wonder and admiration, and its worship was probably the very first form of idolatry. See SUN AND FIRE WORSHIP.

When the true system of the universe became known, one of the first labors of astronomers was to ascertain the distance and size of the sun, and these have been known for some time with tolerable precision; but until lately the most vague and unsatisfactory theories regarding its chemical and physical constitution have continued to prevail.

Within the last few years, however, our knowledge of its chemical and physical con-

stitution has increased with a rapidity probably unequaled in any other branch of science.

Our knowledge regarding the sun is best arranged under three heads: viz., *The general relations of the sun to our globe; the sun's chemical constitution; and its physical constitution.*

Relations of the Sun to the Earth, as the Source of Light and Heat.—In order to appreciate the grandeur of the scale on which solar activity is carried on, it is only necessary to know a few facts relative to the sun, which are best expressed by numbers.

1. *Distance of the Sun from the Earth.*—The difficulty in ascertaining the parallax (q.v.) of the sun arises from the smallness of the base line as compared with the distance of the object. The distance of the observing stations must always be less than 8,000 m.; from this the parallax of the moon, which is only 30 times 8,000, can be observed directly with tolerable nearness. But when the distance is many thousands times the length of the base line, the triangle is "ill-conditioned" or unfavorable to accuracy, and the problem must be approached indirectly. The first attempt to measure the distance of the sun was that made by the Greek astronomer Aristarchus in the third c. B.C., who made it only about one-twentieth of what we now know it to be. Even the great astronomer Kepler in the seventeenth c. could only say that the distance must be at least between 13 and 14 millions of miles. Subsequent estimates—for, owing to the imperfection of the methods and instruments, they were little better than estimates—rose to 80 millions. At last, in 1716, the English astronomer Halley proposed a method of employing the transits of Venus. Accordingly, the transits of 1761 and 1769 were observed in a variety of places; but the results at first deduced were discordant and unsatisfactory, until in 1824 the German astronomer Encke "discussed" the observations of 1769, and arrived at a distance of about $95\frac{3}{10}$ millions of miles; and this number held its place in books of astronomy for about many years. In the mean time, in the absence of transits, other methods, become possible through the growing perfection of astronomical instruments, were tried, and most of them concurred in pointing to a value nearly $3\frac{1}{2}$ millions less than that above stated; so that 91,500,000 came to be accepted as the approximate distance of the sun, until the transit of 1874 should settle it more definitely.

A transit can occur only when the planet is in or near one of her nodes at the time of inferior conjunction, so as to be in a line between the earth and the sun. The coincidence of these two conditions follows a rather complex law. There are usually two transits within eight years of one another, and then a lapse of 105 or 122 years, when another couple of transits occur, with eight years between them. The transit of 1874 was succeeded by that of 1882, and there will not be another until June, 2,004.

The way in which a transit is turned to account may be understood by the help of the accompanying diagram, where E represents the earth; V, Venus; and S the sun. It is to be premised that the *relative* distances of the planets from the sun are well known. Their periodic times can be observed with accuracy, and from these by Kepler's (q.v.) law we can deduce the *proportions* of the distances, but not the distances themselves. It is thus known that if the distance of the earth from the sun is taken as 100, that of Venus is 72. In the fig. then, AV is 28, or about one-third of Va or Vb.

An observer at a station, A, on the northern part of the earth will see the planet projected on the sun as at α , while a southern observer will see it at β . The distance of the sun from Venus being about three times her distance from the earth, it is obvious that

the distance ab will be three times the distance AB ; and it is a great advantage to have the stations A, B, as far apart as possible, as the interval ab is thus increased and its measurement rendered more accurate.

But how is it measured? For each observer sees only one of the spots, and does not know where the other is; and there are no permanent marks on the sun's surface to guide us. The difficulty is got over in the following way: Each observer notes the exact duration of the transit, that is, the time the spot takes to travel from C to D, or from F to G. Now as we know the rate of Venus's motion in her orbit, this gives us the lengths of the lines CD and FG in minutes and seconds of arc. Knowing then the angular diameter of the sun ($32'$) and the lengths of two chords CD and FG, we can easily, by the properties of the circle, find the distance ab between them. This gives us the angle aAb . In the triangle AVb , then, we know the angle at A and the proportion of the sides AV and Vb, and from that we can find the angle AbV or $A\beta B$. Now this is the quantity sought, being the parallax of the sun as seen from two stations on the earth. Whatever the distance AB actually is, the angle is reduced to correspond to a distance equal to the earth's semi-diameter. The parallax deducted by Encke, as above referred to, was only $8.5776''$, while the parallax corresponding to the other smaller measurement above stated is $8.94''$. The advantage of this roundabout procedure is that a comparatively large angle (aAb) is measured in order to deduce from it a smaller ($A\beta B$), so that any error in the measurement is diminished in the result.

The transit of 1874 was observed at more than fifty stations, astronomers from all the civilized world taking part in the work. The labor of discussing and comparing the observations has not yet been overtaken, but several partial results have been announced,

which still show considerable discrepancy. The chief source of uncertainty arises from the difficulty the observers found in determining the exact moment of "ingress" and "egress" of the planet, owing to the dense atmosphere of the latter rendering the limbs of the two bodies indistinct and distorted. Much was expected from the multitude of photographic pictures taken, but they have proved a failure. They are said to lack the necessary sharpness, and to be liable to other sources of error. The first partial discussion of the British observations gave, according to the astronomer royal, a result of $93\frac{2}{10}$ millions of miles. A more extended discussion since announced results in $92\frac{5}{10}$ millions of miles.

Elaborate arrangements were made, on an international plan, for observing the transit of 1882, and attempts made to obviate the defects of previous observations. Previous to this astronomers were turning with greater hope to other methods, especially to observations of Mars, and of some of the minor planets. From observations of Mars made in 1862, the American astronomer Newcomb deduced a distance of $92\frac{2}{10}$ millions of miles. The velocity of light, which has been determined by the ingenious optical experiments of Foucault and others, has also been pressed into the service of the problem. The aberration of light (q.v.) results from the relation of the velocity of light to that of the earth's motion in her orbit; and from the observed amount of the aberration we are thus able to deduce the earth's velocity. From knowing then the time of the earth's revolution, we can find the circumference of her orbit, and hence her distance from the sun. The most careful investigation by this method gives a distance of 93 millions of miles. An ingenious method of observing the parallax of Mars at its opposition, first suggested by the astronomer royal, but carried out by Mr. Gill on the island of Ascension in 1877, promises still more satisfactory results. The essence of the method consists in this, that instead of depending upon two sets of observers at different parts of the earth, one observer and one station are made to suffice. One observation is taken in the evening when the planet is rising, and another in the early morning when it is setting. In the mean time the rotation of the earth has transported the observer 6,000 or 7,000 m. through space, and this forms his base line. Mr. Gill's observations were made by means of the heliometer, the most effective of instruments for such purposes. From such of his observations as had been reduced at the end of 1878, Mr. Gill announces his belief that the sun's distance will prove to be nearer to 93 than to 92 millions of miles.

The other important numerical facts relative to the sun are the following: Its *diameter* calculated on the basis of the shorter distance hitherto received, is, in round numbers, 850,000 m., or more than 107 times the mean diameter of the earth; so that the *volume* or bulk of the sun exceeds that of the earth 1,200,000 times, and is 600 times greater than the bulk of all planets at present known, together. The *mass* of the sun, or quantity of matter it contains as measured by weight, exceeds that of the earth only 300,000 times; and thus it appears that the matter of the sun has only one-fourth the density of that of the earth. From this and other facts, it is inferred that the matter of the sun exists for the most part in a gaseous condition. Still his mass is 740 times greater than the masses of all known planets put together. The *period of rotation* of the sun upon its axis, which Galileo was the first to calculate from observations of the sun-spots, and which takes place in the same direction as that of the earth, is about 25 days 8 hours. It appears, however, that this period varies according to the solar latitude of the spots from which it is calculated. The *inclination* of the axis of the sun to the ecliptic is about $7\frac{1}{4}^{\circ}$, and the *longitude of the ascending node* is about $74^{\circ} 30'$.

2. The form or *figure of the sun* has been the subject of recent investigations. The polar and equatorial diameters of the sun's disk as observed, have been supposed to differ, though by a very small quantity only. The photographs of the sun do not quite agree in the amount of the value for the diameter with that given by observations.

The general laws by which the relation of our earth to the sun, as the source of light and heat, is governed, are of the most simple kind. The rays which emanate from the sun's disk into space proceed in diverging lines, and, on arriving at the earth, their intensity will be inversely proportional to the square of the sun's distance. This may be called the primary law; but the more obvious phenomena of solar heat and light are manifested to us under a secondary law depending on the obliquity of incidence of the sun's rays. See CLIMATE; EARTH; HEAT; LIGHT, etc.

3. *Chemical Constitution of the Sun.*—Astronomy has weighed and measured the sun long ago, and in our days chemistry, aided by physics, makes an analysis of it. The way in which this surprising result is arrived at is explained under SPECTRUM. The main fact on which the method rests is briefly this: that a substance, when comparatively cold, absorbs the very same rays which it gives out when heated. Hence it was inferred by Kirchhoff that if there was sodium or iron in a comparatively cold state in the solar atmosphere, above the source of light, these substances would produce black lines corresponding in spectral position with the bright lines which they give out when heated. On this principle the presence in the solar spectrum of hydrogen, magnesium, calcium, sodium, and metals of the iron group has been ascertained with something like certainty. There are less clear indications of other metals, such as zinc and lead; while metals of the tungsten, antimony, silver, and gold classes have been searched for in vain. Of the metalloids, such as oxygen, carbon, nitrogen, sulphur, and the like, none had been detected till, in 1877, Prof. Henry Draper of America announced the discovery

of oxygen. The presence of these substances in the sun is hardly doubted, but their identification is difficult. A chief source of complication in research of this kind is the effect on the spectra of substances produced by differences of temperature and pressure. Excessive heat seems to dissociate the groups of atoms forming the molecules into simpler groups, and thus produces a different spectrum difficult to recognize. The labors of Lockyer, Huggins, Janssen, Draper, and others are directed toward overcoming these and other obstacles.

4. *Physical Constitution of the Sun.*—Since the first discovery by Galileo of those remarkable phenomena on the sun called *sun-spots*—dark patches with an area frequently exceeding several times the surface of the earth—an immense variety of theories as to the probable constitution of the solar body has been brought forward by nearly every observer. Solar photography promises valuable aid in this research by enabling us to keep a permanent record of passing phenomena, ready at any time for deliberate measurement and comparison.

One of the most important discoveries in connection with sun-spots, science owes to Dr. Alexander Wilson of Glasgow, who, in the year 1769, observed certain general and remarkable features of sun-spots, which enabled him to establish the significance of these phenomena for a solution of the question as to the sun's physical constitution. These features are as follows: When a spot was near the middle of the sun, it was found to consist of a dark central part, called the *nucleus* or *umbra*, and around this was a comparatively brighter envelope, called the *penumbra*, and at such a time both parts were distinctly visible. But as the spot approached one border, the penumbra on the side nearest the observer became gradually more and more foreshortened, while the penumbra on the other side grew broader and broader, and at length, as the spot was disappearing—that is, passing the edge of the limb—the near side of the penumbra, as well as the dark central part, entirely vanished, nothing remaining except the opposite penumbra. When a spot made its appearance on the other side of the border, Wilson noticed the same phenomena in an opposite order, and soon discovered that they were nearly universal. It followed from these observations at once that every spot presents the appearance of a funnel-shaped opening in the sun's body, which, by the rotation of the latter, successively presented the described appearances. These observations have been abundantly confirmed by the photographic records of Messrs. De la Rue, Stewart, and Loewy.

Schwabe showed, as the result of nearly 40 years' observations, that the number of groups of sun-spots is not the same from year to year, but has a maximum about every 10 or 11 years; and Gen. Sabine recorded the wonderful fact that the various epochs of maximum spot frequency are also those of maximum disturbance of our earth's magnetism. Here, then, we have a very curious bond of union between the sun and the planets of our system.

It was next shown by Carrington that sun-spots have a proper motion of their own—those near the solar equator moving faster than those near the poles.

While spots are darker than the general surface of the sun, there are also frequently observed patches brighter than the general surface. These are called *faculae*, and they generally accompany spots, most frequently in their wake; but they are only distinctly visible near the sun's limb, and lose their specific luminosity near the center of the sun's disk.

Another phenomenon connected with our luminary is not less remarkable than sun-spots. This is the red flames, or *protuberances*, which were first observed surrounding the sun's disk on the occasion of a total eclipse, but which by ingenious methods of observation can now be rendered visible even when the sun is not eclipsed. This colored envelope, less brilliant than the *photosphere*, or light-giving surface, and having a mean height of 5,000 or 6,000 miles, is known as the *chromosphere*, and seems to consist mainly of incandescent hydrogen, jets of which are seen at times to be projected to a height of 200,000 miles. The velocity of these movements has been calculated to exceed at times 120 miles a second. Above the chromosphere there is a far deeper layer of cooler, sub-incandescent gases, among which is an unknown substance, which chiefly composes the outer portion, and is apparently lighter than hydrogen. These gaseous envelopes, extending together to 300,000 or even 500,000 miles above the photosphere, are now believed to cause the appearance called the *corona*, or white halo, which is seen to surround the dark body of the moon during an eclipse of the sun.

If a spot be a hollow, as we have reason to suppose, it is only necessary to believe that there has been a descending current of this cold absorbing atmosphere to account for the want of luminosity. In like manner, on this hypothesis, a facula will be a portion of the luminous matter, which has been removed high up into the atmosphere, and which thus escapes the absorbing influence of the atmosphere. A spot may thus be supposed, to be produced by two currents—one ascending, and carrying the hot luminous matter up; the other descending, and carrying the cold atmosphere down. The photosphere is thus in a constant state of agitation like ebullition.

Spots and their accompanying faculae are an indication of the activity of those "convection currents" by which heat is brought to the surface to replace what has been radiated off. Their temporary prevalence then is held to be a sign of more than ordinary solar activity or expenditure of energy. This is palpably manifested on our globe in the greater magnetic disturbance that takes place when sun-spots are numerous, as

before mentioned. The diurnal range of the magnet freely suspended in the Kew observatory, shows an unmistakable correspondence with the waxing and waning of the spotted area on the sun; and the frequency of auroræ is found to be in perfect correspondence with prevalence of spots. It is natural to seek to connect cycles of weather with the spot-period of the sun, but nothing has yet been conclusively established. A coincidence has seemingly been made out between the recurrence of famines in southern India through deficient rain and the period of minimum spots; but the coincidence does not hold for other localities. Attempts have even been made to bring commercial crises and other recurring events into the spot-cycle.

As to the cause of the periodicity of sun-spots, observations made at Kew seem to establish a connection between the behavior of spots and the proximity of prominent planets; and it may thus be found that the recurrence of certain planetary positions in some way determines the spot-period.

It was thought that the transit of 1874 would furnish data for obtaining the sun's parallax to within 0."10, but the result has been disappointing. The distance obtained from the American photographs—213 in number—is 92,028,000 m., using the figures given by Col. Clark for the dimensions of the earth. The transit method of determining the sun's distance has been found to be not as accurate as it had for a long time been supposed; still a large number of thoroughly equipped expeditions observed the transit of 1882, and the results were generally satisfactory. Prof. Ball places the sun's distance at 92,700,000 m., and estimates the error to be not more than 300,000 m. Dr. Hastings, in 1879-80, conducted a series of experiments, which resulted in finding a slight difference between the spectra of the center and the limb of the sun, the difference being about the same as that between the spectra of a spot and the unbroken photosphere. From his investigations he formulated a theory of convection currents, starting from a lower level, where all the substances would be vaporized; as it rises heat is lost, and condensation and precipitation take place. This precipitation forms the granules. When a downward convection current is increased, there is a rush of vapors to that point, carrying along the precipitated clouds (or smoke) which at this point congregate and form a spot. During the total eclipse of 1883, May, the corona was carefully studied, and Dr. Hastings concludes that it is due mainly to diffraction phenomena, and that the corona is only a narrow belt. Janssen also finds in it a large amount of reflected light. In one coronal stream Tacchini discovered green and yellow bands, which are characteristic of comets. Huggins has been trying to obtain photographs of the corona without an eclipse, and it has been thought that he has gotten a true picture, at least as far as 8' from the sun's limb. Photographs of the corona taken near the maximum period of spots have been found alike, and those at the minimum period also alike, seeming to establish a connection between the spot periods and the corona. Prof. Langley, in 1882, conducted a series of experiments upon the summit of Mt. Whitney, from which he concludes that the heat radiation of the sun is much greater than has been supposed. In 1882 Dr. Siemens explained, before the Royal Soc. of London, a new theory of the origin of solar heat: he supposes space to be filled with something more substantial than ether; or that oxygen, hydrogen, nitrogen, and some of their compounds exist in space in a highly rarefied condition. The attraction of the sun causes a constant inflow of this cosmical matter, and its rotation projects it out in a stream at the sun's equator. During the inflow these substances pass from their rarefied condition to one of greater compression and higher temperature, until, near the sun's surface, they ignite, developing great heat; and after a while they are thrown off at the equator into space, where they again become dissociated. On this hypothesis it is this constant inflow and outflow that keeps up the undiminished heat of the sun.

SUN AND FIRE WORSHIP. All investigation tends to show that nature-worship was the basis of all polytheistic religions, and that the chief deities of the several mythologies were originally personifications of the sun, or of particular influences of the sun. The original solar nature of Jupiter, Zeus, Odin, Baal, Amen Ra (see EGYPT), Indra, etc., can hardly be mistaken. See those heads; also SCANDINAVIAN MYTHOLOGY, PHENICIA; and for a full development of the subject, Max Müller's essay on *Comparative Mythology* (Oxford Essays; 1856). The actual sun, however, still continued an object of worship, more especially as in the abstract and more strictly personal gods, moral and intellectual attributes came to predominate over and obscure the physical (see HELIOS); and with the worship of the sun was more or less closely associated that of fire—his representative on earth. See PARSEES, NEEDFIRE, BELTEIN.

The most complete system of sun-worship that we have any account of is that existing in Peru when discovered by the Spaniards (1526). "Our northern natures can hardly comprehend how the sun, and the moon, and the stars were imaged in the heart of a Peruvian, and dwelt there; how the changes in these luminaries were combined with all his feelings and his fortunes; how the dawn was hope to him; how the fierce mid-day brightness was power to him; how the declining sun was death to him; and how the new morning was a resurrection to him; nay, more, how the sun, and the moon, and the stars were his personal friends, as well as his deities; how he held communion with them, and thought that they regarded every act and word; how, in his solitude, he fondly imagined that they sympathized with him, and how, with outstretched arms he appealed to them against their own unkindness, or against the injus-

tice of his fellow-men."—Helps's *Spanish Conquest of America*. The Incas, as the Peruvian monarchs were called, claimed to be children of the sun, and his representatives on earth. Their government was a despotic theocracy, of which the Inca was both high-priest and king. In Cuzco, the capital, stood a splendid temple to the sun, all the implements of which were of gold. On the w. end of the interior was a representation of the sun's disk and rays in solid gold, so placed that the rising sun, shining in at the open e. end, fell full upon the image, and was reflected with dazzling splendor. In the place or square of the temple, a great annual festival was held at the summer solstice. The multitude, assembled from all parts of the empire, and presided over by the Inca, awaited in breathless solemnity the first rays of their deity to strike the golden image in the temple, when the whole prostrated themselves in adoration. Sacrifices, similar to those of the Jews, were offered on the occasion, and bread and wine were partaken of in a manner strikingly resembling the Christian communion.

SUNBIRDS, *Cinnyridæ*, a family of birds of the order *insessores* and tribe *tenuirostres*, which may be regarded as a connecting link between the creepers and the humming-birds, and as occupying nearly the same place in the tropical parts of the Old World which belongs to the humming-birds in America. They are all of small size, although none are so small as the smallest humming-birds; they rival humming-birds in brilliancy of plumage, and like them they feed on the juices of flowers, which they suck by their long bill; they do not, however, flutter on the wing when feeding, like humming-birds, but perch on or beside the flower into which the bill is to be inserted. The species are very numerous, and are natives of the southern parts of Asia, the eastern Archipelago, and Africa. The resplendent metallic plumage belongs only to the male, and only to the breeding season.

SUNBURY, a co. in s.e. New Brunswick, crossed by branches of the Canadian Pacific railroad; drained by St. John river; 1200 sq. m.; pop. '91, 5762. The surface is mostly level and densely timbered; the soil is fertile. Co. seat, Oromocto.

SUNBURY, borough and co. seat of Northumberland co., Pa.; on the Susquehanna river, and the Northern Central, the Pennsylvania, and the Philadelphia and Reading railroads; 56 miles n. of Harrisburg. It is an important shipping point for coal; has silk and saw mills, rolling mill, nail works, coffin and casket factory, several large railroad machine and repair shops, hosiery factory, and door and sash mills; and contains a national bank, high school, and electric street railroad plant. It was founded in 1772. Pop. '90, 5930.

SUNDA ISLANDS, that great chain of islands belonging to Malaysia, running e., including four large islands, Sumatra (q. v.), Java, Borneo and Celebes, and many smaller ones, Timor (q. v.), Bali, Lombok, Sumbava, Floris, Sumba, etc., and separating the Java sea from the Indian ocean. Sunda strait is a passage, from 70 to 90 m. in breadth, between Sumatra and Java.

SUNDAY. See **SABBATH**; **LORD'S DAY**.

SUNDAY-SCHOOLS were founded about the close of the year 1781 by Robert Raikes, a printer in Gloucester. Business leading him into the suburbs of the town, inhabited by the lowest class of the people, he was struck with concern at seeing a group of children, miserably ragged, at play. He was informed that "on Sunday the street was filled with a multitude of wretches, who, having no employment on that day, spent their time in noise and riot, playing at chuck, and cursing and swearing." To check this deplorable profanation of the Lord's day he engaged four women, who kept dame schools, to instruct as many children as he should send them on the Sunday, in reading and the church catechism, for which they were to receive one shilling each. In a short period a visible improvement was effected both in the manners and morals of the children, who came in considerable numbers; they attended church with their mistresses, and a great many learned to read and say their catechism. Such was the origin of the Sunday-schools. This excellent scheme was noticed in the Gloucester newspaper in 1783; but a letter of Mr. Raikes, from which the above account is taken, published in the *Gentleman's Magazine* in 1784, first drew general attention to it. Numerous schools, formed on the same model, sprang up in all the principal towns; and a society, under high patronage, was formed in London in 1785 for the establishment and support of Sunday-schools throughout the kingdom, which in 14 years expended £4,000 in payment of teachers. Her majesty, Queen Charlotte, admitted Mr. Raikes to an audience, and expressed her high approbation of his plan. This was the first stage of the Sunday-school. The great impediment to its prosperity was the expense of hiring so many teachers. Even in Gloucester, the birthplace of the Sunday-schools, after Mr. Raikes's death in 1811, all the Sunday-schools were closed for a time owing to want of funds. Whoever first conceived the idea of gratuitous instruction has nearly as great merit as Mr. Raikes himself; but probably it was suggested by necessity to many minds in different places at the same time. It was the means of starting Sunday-schools on a new career of success, and the idea spread so rapidly that, by the year 1800, the teaching was almost universally gratuitous. A higher class of teachers offered their services; the schools ceased to be filled by the very poorest alone; handsome buildings were erected in connection with the different churches and chapels, or by general subscription, and

that system was organized which has covered the land with schools. The secular teaching, which in certain instances included writing and arithmetic, was not of a very high order; but it placed the key of knowledge in the hands of multitudes who would otherwise have been unable to read; and the religious instruction with which it was combined has molded the character of some of the best men in England. In 1803 the Sunday-school union was formed, which, by its numerous publications, its traveling agents, and its connection with branch societies in every part of the kingdom, has exercised great influence on the Sunday-school cause. The institute of the church of England, which operates in a similar manner, is of later date. Within the last 40 years the Sunday-school has entered upon a third stage of its history. The improvement and multiplication of week-day schools obviate the necessity for teaching reading in Sunday-schools, so that they have gradually become restricted to religious instruction. Sunday-schools have prospered in Scotland, where religious teaching alone ever prevailed, and the stability of this modern invention is accomplished.

The Sunday-school found its way into Scotland as early as the year 1782; but it was not till 1786, when the society for promoting religious knowledge among the poor was formed, that it was publicly recognized; nor till 1797, when the gratis Sunday-school society was originated, that schools became general. At first they met with considerable opposition from portions of the ecclesiastical courts, but they are now supported by all the churches. Sunday-school unions exist in Edinburgh, Glasgow, and most of the large towns. The names of Dr. Chalmers, James Gall, the author of the *Lesson System*, and David Stowe, the author of the *Training System*, deserve mention in connection with the progress of Sunday-schools in Scotland. In Ireland Sunday-schools had been partially anticipated in county Down in 1770; but it was not till 1785 that the system pursued by Mr. Raikes was adopted, since which its history has been analogous to that of England. The Sunday-school society for Ireland was established in 1809. Sunday-schools were introduced into New York in 1816, through the exertions of some benevolent ladies, from which they have spread themselves through the United States. They are now to be found wherever the English tongue is spoken. They thrive vigorously in the Protestant churches of France; and more recently have been planted in parts of Germany and of Italy. The first permanent Sunday-school organization in the United States, of which there is authentic record, was the First-day or Sunday-school society, formed in Philadelphia, 1791. It was composed of members of different denominations including the society of Friends. Its constitution required that the instruction given in its schools should be "confined to reading and writing from the Bible, and such other moral and religious books as the society may direct." The New York Sunday-school union was instituted, 1816; the Philadelphia Sunday and adult school union, 1817. These three societies recognized the union of different denominations, and led to the organization of the American Sunday-school union at Philadelphia, 1824. The suggestion that such an association should be formed came from New York. Its object was to concentrate the efforts of Sunday-school societies in different sections of the United States, and to endeavor to plant such schools wherever there is a population. As the new states were settled and the various religious denominations were strengthened, more attention was given by each to its own Sunday-schools, and denominational unions to promote them were formed. In the early history of the schools the chief thing expected of the children was to commit to memory portions of scripture, and the chief employment of the teachers was to hear the recitations. Afterward the question book was added to the recitation, and at length in a great degree superseded it. Still later came the lesson helps, golden text, blackboard exercises, etc. In the first schools, reward tickets were given, and when they had sufficiently accumulated were exchanged for books. This stimulated the production of volumes of suitable character, and from this the Sunday-school library has been developed. In 1890 the number of Sunday-schools in the United States, exclusive of the Roman Catholic and Hebrew schools, was reported at 108,939, with 1,151,340 teachers and officers and 8,649,131 scholars. The Roman Catholic Sunday-schools in the United States contained upward of 700,000 scholars. In England and Wales the number of scholars attending schools of all denominations was 6,350,266; in Scotland, 711,188; in Ireland, 338,231; in France, 53,110, and in Germany, 431,221.

SUNDERBUNDS, a tract of British India, presidency of Bengal, consists of a number of low islands, forming the delta of the Ganges. The tract extends e. from the mouth of the Hoogly to the island Rabanabad, is 158 m. long, 75 m. broad, with an area of 7500 sq. m. Only the northern part is inhabited, the south being mainly jungle, abounding in tigers, leopards, buffaloes, crocodiles, and snakes. The only town worthy of mention is Port Canning, connected with Calcutta by rail. The scanty population (1882, 413) raise rice, indigo, jute, betel, and sugar-cane.

SUNDERLAND, a thriving municipal and parliamentary borough and seaport, in the county of Durham, 14 m. n.e. of the city of that name, at the mouth of the Wear. The town may be said to be co-extensive with the parliamentary borough, and to include the suburbs of Bishop-Wearmouth on the s. bank, and Monk-Wearmouth and Southwick on the n. bank of the river, connected with Sunderland proper by an iron bridge of one arch, 236 ft. long, and nearly 100 ft. above the river at low water. The bridge over the Wear was erected in 1796, but was repaired and widened in 1858 by Robert Stephenson (q.v.), at the cost of about £40,000. On both sides of the river there are extensive wet

docks, much of the area of which has been reclaimed from the sea. The harbor, which is defended by batteries, is formed by two great piers, one 650 yards and the other 590 yards in length; and the port is resorted to by vessels of the largest tonnage, from all commercial countries. After Newcastle, Sunderland is the greatest coal-shipping port in the world. The *Pemberton* coal mine is said to be the deepest in existence. The sanitary condition of the town has been recently greatly improved, a large new infirmary was built in 1867, and in 1868 a spacious workman's hall. Shipbuilding is one of the principal branches of industry. Machinery, glass, earthenware, ropes and chains, anchors, and other iron-wares, are very extensively manufactured. The public park of Sunderland, about 70 acres in extent, is adorned with a bronze statue of gen. sir Henry Have-lock, a native of the town, and commands a fine view of the sea. The village of Roker, a mile from the town, is much resorted to for sea-bathing. Fishing is carried on to a considerable extent. Pop. of parliamentary borough, which returns two members to the house of commons, '91, 131,015.

SUNDERLAND, ROBERT SPENCER, second Earl, was the only son of HENRY, first earl, who had been raised to the peerage in 1643, for his exertions in the royal cause. He was born in 1640, and after serving as ambassador to several courts, became in 1679 secretary of state. He had by this time manifested remarkable talent. Bishop Burnet says of him, "He had a superior genius to all the men of business that I have yet known." At first, he united with Essex and Halifax in opposing Shaftesbury, who wished to set Monmouth on the throne, and favored the exclusion of the duke of York. He encouraged the king to persevere in the degrading French alliance, and, with the duchess of Portsmouth, to whom he attached himself, negotiated a treaty by which, in consideration of an annual pension from the French king, Charles was to agree to assemble no parliament for three years. Before the end of the year, he had shaken off Essex and Halifax; and a new triumvirate, consisting of himself, lord Hyde, and Godolphin, succeeded to the confidence of Charles II. The treaty with France was broken off, and Sunderland, who was now afraid of the whigs, engaged the king in a more popular alliance with Spain. After the dissolution of the last of the exclusion parliaments, he lost his office; but the duchess remained faithful to him in disgrace; and by her influence, and that of lord Rochester, he was, in 1682, says Bishop Burnet, "upon great submission made to the duke [of York], again restored to be secretary." He remained in office until the accession of James II., when his influence in the ministry became greater than ever. He who had so often saved himself in the former reign by the influence of the duchess of Portsmouth, now secured himself another patroness in the king's second wife, the Princess of Modena. Although there is reason to believe he gave some encouragement to Monmouth in his rebellion, he managed, with consummate art, to obtain the entire confidence of James, and in 1685 became prime-minister. He was intrusted with a knowledge of the king's intention to establish the Roman Catholic religion as the national church, and was indeed the only minister in whom the king confided. In 1687 he privately conformed to the Roman Catholic church, and afterward openly professed his conversion. His influence was so great, that James would grant no favor until he had asked the question, "Have they spoken to Sunderland?" and when told that this nobleman got all the money of the court, he would reply, "He deserves it." Yet we find him about this time in correspondence with the Prince of Orange, afterwards William III. The princess Anne described Sunderland as "the subtillest workingest villain that is on the face of the earth." Burnet says he entered into a particular confidence with the prince of Orange, which he managed by his uncle, Mr. Sidney, who was sent envoy to Holland. With profligate but masterly dexterity, he contrived to deceive both his master and Barillon, and to keep them in ignorance of the events that were passing in Holland. When the prince arrived in England, Sunderland and his wife went to Amsterdam, whence he wrote to the new monarch, claiming his favor and protection on the ground that he had all along been in his interest. In 1691 he was allowed to return to England, and to kiss the king's hand. In 1695 William III. spent a week at Sunderland's house at Althorpe. It was imputed to him that he had changed his religion, in the late reign, in order the more effectually to ruin King James; and it was generally believed that he had rendered king William, when prince of Orange, some signal services, which no one else could have done. This belief gained credit from the favor shown him by William. He was made lord chamberlain, and as such took his seat at the head of the council table. After directing affairs as the acknowledged head of the government, he resigned office in 1697, and retired to private life. He spent the rest of his days at Althorpe, where he died in 1702. He never shone as a public speaker. He had, however, unusual abilities for business, and a rare skill in the art of insinuation. He possessed exquisite courtly talent, extraordinary versatility, and a flexibility of principle too common in his day, but carried by him to the most reprehensible lengths. By his wife, Anne, daughter of the second earl of Bristol, he left CHARLES SPENCER, third earl, who was born in 1674. He was described by Evelyn as a youth of extraordinary hopes, very learned for his age, and ingenious. He was for some time secretary of state in the reign of Queen Anne, and under George I. rose to be all-powerful; but in 1721, being accused of receiving £50,000 worth of the fictitious stock distributed by the direc-

tors of the South Sea scheme (q.v.), in order to bribe the government, he was acquitted only by an inconsiderable majority and that from party considerations, and the indignation of the public made him resign his office. He died in 1722, not without suspicion of having intrigued, after his fall, for the restoration of the tories, if not for the return of the pretender. Sunderland was a type of the political morality, or rather immorality, of a disgraceful age, when the greatest statesmen made no scruple of sacrificing either their own party, or the interests and dignity of the nation, to personal ambition. His title descended to CHARLES, his second son, who succeeding, 1733, to the honors of his illustrious grandfather, John Churchill, the earldom of Sunderland became absorbed in the dukedom of Marlborough. His third son, JOHN, was ancestor of the earls Spencer.

SUN-DEW, *Drosera*, a beautiful and interesting genus of plants of the natural order *dioscoreaceæ*, several species of which are natives of America, found in bogs and moist heathy ground. A common species is the ROUND-LEAVED SUN-DEW (*D. rotundifolia*), which is plentiful in almost all places suitable to the plant. The leaves all spring from the root, and spread out in a rosette, from the center of which springs the flower-stem or scape, with a raceme of flowers all on one side. The leaves of this and the other species are fringed and beset in all parts with hairs, which bear at their extremity viscid glands, and the irritation of these glands causes them to contract and fold up, so that insects are imprisoned by them. Recent observation has proved that these insects are actually digested by the plant, their nutritive material being absorbed by it. Compare the *dionæa* (q.v.), and see Darwin's *Insectivorous Plants* (1875). The whole plant is acrid, curdles milk, and has a reputation for removing corns, bunions, and warts. An agreeable liqueur, called *rossoli* (*ros solis*) is made by infusing the plant in brandy, with sugar, etc.

SUN-DIAL. See **DIAL**.

SUNFISH, *Orthogoriscus*, a genus of fishes of the family *diodontidæ* (see **DRODON**), having the body compressed, and not capable of inflation, as in the other *diodontidæ*; abruptly terminating in a very short tail; the dorsal and anal fins long and pointed, united to the short tail-fin; each jaw furnished with a cutting edge of bone instead of teeth. The species chiefly inhabit the seas of warm climates, but two are occasionally seen on the coasts of Britain. The SHORT SUNFISH (*O. mola*), when young, is almost perfectly round, but becomes rather more elongated when full grown. The name sunfish is variously regarded as derived from the form of the fish, and from its habit of floating at the surface of the water in fine weather, as if to enjoy the sunshine. It attains a large size, being sometimes more than six ft. in length, and is captured by sailors. Its flesh is white and well flavored, somewhat resembling that of the skate. The liver yields a large quantity of oil, which is in repute among sailors as an external application for the cure of sprains, rheumatism, etc. The OBLONG SUNFISH (*O. oblongus*), of which specimens have also been taken on the British coasts, but more rarely, is of a longer form. It also attains a large size. The sunfishes feed upon sea-weeds.

SUNFLOWER, *Helianthus*, a genus of plants of the natural order *compositæ*, suborder *corymbifera*, having large flowers; the florets of the ray strap-shaped, without stamens or pistils, yellow or orange; the florets of the disk tubular, perfect, yellow or purplish-brown; the flowers solitary or in corymbs, with an involucre of numerous leaves; the fruit compressed, with a pappus of two or more deciduous scales. The species are numerous, all natives of America; large herbaceous plants, with opposite or sometimes alternate undivided leaves. The ANNUAL SUNFLOWER (*H. annuus*), common in our flower-gardens, is a native of tropical America, where it sometimes attains a height of 20 feet. The stem is thick and rough; the flowers solitary, and from one foot to two feet in diameter, nodding; the leaves heart-shaped-ovate. This plant is now cultivated in almost all parts of the world, and in the s. of Europe is sometimes a field-crop; the seeds being valued as food for cattle and poultry, and on account of the oil which they yield, which is little inferior to olive oil. An acre of good land produces about fifty bushels of seed, each bushel yielding a gallon of oil. The seeds are also used like almonds for making demulcent and soothing emulsions; and in some parts of Europe, a bouilli is made of them, which is used as food for infants. The American Indians make bread of them. The flowers abound in honey, and are much frequented by bees. The leaves are good fodder for cattle. The stems are used for fuel, and yield much potash.—The Jerusalem artichoke (q.v.) belongs to this genus.

SUNFLOWER, a co. in n.w. Mississippi, traversed centrally by the Sunflower river; 720 sq.m.; pop. '90, 9384. Co. seat, Indianola.

SUNFLOWER STATE. See **STATES**, **POPULAR NAMES OF**.

SUNN, *Crotalaria* (q.v.) *juncea*, a leguminous plant, native of India, which has been in general cultivation there from time immemorial, for the fiber of its bark. It has a strong general resemblance to Spanish broom. It is, however, an annual plant. The plant is cultivated not only for its fiber, but as food for milch-cows. The seed is generally sown in April or May, and in August it is pulled, or cut close to the ground—when grown for its fiber—laid in long rows till the leaves begin to rot and separate from the stalks, and steeped in water for a few days, till the bark separates freely. The

fiber is not so strong as hemp; but good cables, canvas, and cloth are made of it. It is now imported in considerable quantity into Britain. It is known by various names. *Taag* is one of its Indian names, and it is sometimes called *brown hemp*, *Bengal hemp*, etc. The confusion of names makes it difficult to ascertain the quantity imported.

SUNNA (Arab. custom, legal usage), originally denotes among Moslems the sayings and the example of Mohammed and his community, provided they are in accordance with the Koran, the meaning of which, however, is itself explained by the Sunna. The term is therefore (though incorrectly) used for the collections of moral and legal traditions traced to the prophet, which supplement the Koran, somewhat like the Mishna (q.v.), which supplements the laws of the Pentateuch. The Sunna not only comprises religious doctrines and practice, but also civil and criminal laws, and the usages of common life: the way to eat and to drink, and to dress, and the like. This tradition is first heard of during the civil wars among the adherents of the new faith, about half a c. after the flight. The single traditions, as we now possess them, rarely exceed six lines. The diction is carefully wrought, and the form is that of a dialogue. For the credibility and canonicity of a tradition, it was originally necessary that it should have been *heard* by one truthful witness; but this law was much relaxed in after-time. At the end of the 3d c. (H.), a countless number of individual collections (Mosnad), mostly of an apocryphal character, had been produced by different theologians, but the first who sifted them critically, and without regard to any special theological system, was Bochary (d. 256 H.). His collection contains 7,275 single traditions, 4,000 of which, however, occur twice in the work. Moslim, his pupil, supplemented Bochary with another collection, containing 12,000, again including 4,000 repetitions. Besides these, there are four more "canonical" collections; by Abû Dawûd (d. 275 H.), Tirmidzy (d. 279), Nasâ'î (d. 303), and Mâga (d. 273). The Sunna, as we have it in these collections, contains, broadly speaking, more truth than it is generally supposed to contain, and, critically used, is, besides the Koran, the most authentic source of Islam. A selection from the different collections (both canonical and otherwise), called *Mishcat Al Masabih*, has been translated into English by capt. Matthews (Calcutta, 1809). Fragments from Bochary are found in a German translation, by Hammer, in the *Fundgruben des Orients*.

SUNNITES, traditionists or believers in the Sunna (q.v.); the name of the "orthodox" Moslems as opposed to the Shi'ites (q.v.). They are subdivided into four principal sects, who, though at issue on different minor points, yet are acknowledged by each other to belong to the faithful, and to be capable of salvation, and they each have a special oratory at Mecca. The first of these sects are the Hanefites, founded by Abu Hanifa, who died 150 years after the Hegira. They are emphatically called "the followers of reason," whilst the other three are guided exclusively by tradition. They allow reason to have a principal share in their decisions on legal and other points. To this sect belong chiefly the Turks and Tartars. The second sect are the Malekites, founded by Malek Ibn Ans, who died about 180 H. at Medina. As one of the chief proofs of his real piety and humility, it is recorded that when asked for his decision on 48 questions, he would only decide on 16, freely confessing his ignorance about the others. In Barbary and other parts of Africa, the greatest part of his adherents are found. Mohammed Al Shâfe'i, born in Palestine, 150 H., but educated in Mecca, is the founder of the third sect, the Shâfe'ites. He was a great enemy of the scholastic divines, and seems altogether to have been of an original cast of mind. He never swore by God, and always took time to consider whether he should at all answer any given question or hold his peace. The most characteristic saying recorded of him is, "Whosoever pretends to love both the work and the Creator at the same time, is a liar." He is accounted of such importance, that, according to his contemporaries, "he was as the sun to the world, and as health to the body;" and all the relations of the traditions of Mohammed were said to have been asleep until he came and woke them. He appears to have been the first who reduced Moslem jurisprudence into a method, and thus made it, from a number of vague sayings, a science. His followers are now chiefly found in Arabia and Persia. Ahmed Ibn Hanbal founded the fourth sect, the Hanbalites. He was born 164 H., and was a most intimate friend of Shâfe'i. His knowledge of the traditions (of which he could repeat no less than a million) was no less famed than was his piety. He taught that the Koran was not created, but everlastingly subsisted in the essence of God; a doctrine for which he was severely punished by the caliph Almotasem. On the day of his death, no less than 20,000 unbelievers (Jews, Christians, and Magians) are said to have embraced the Mohammedan faith. Once very numerous, the Hanbalites now are but very rarely met with out of Arabia. On the differences between the Sunnites and Shi'ites, see SHI'ITES.

SUNSTROKE (INSOLATION, THERMIC FEVER, HEAT APOPLEXY, HEAT ASPHYXIA, THERMOHÆMIA, ERETHISMUS TROPICUS, HEAT FEVER, COUP DE SOLEIL). Two distinct conditions of the human body must be recognized as produced by exposure to heat.

There is a certain similarity in their symptoms, but a wide difference in their immediate pathology and in the indications for treatment. Although their individuality was pointed out many years ago, they have frequently been confounded by writers, and the terms heat exhaustion and sunstroke have not infrequently been used as synonymous. They are here considered as separate affections.

I. *Heat Exhaustion*.—Any one who has been long exposed to high temperatures, under conditions requiring much physical exertion, must have noticed the feeling of general weakness and relaxation which results.

Our every-day experience reaches this far; a step further brings up to us a case in which acute symptoms are severe enough to cause alarm. The attack may come on slowly, but may be as abrupt as in true sunstroke; and the severest cases may happen in the strong and robust as well as in the weak and feeble. The mind is generally clear, the pulse rapid and feeble, the surface of the body cool, the voice weak, muscular weakness marked, and the feeling of exhaustion extreme. This gives a picture of an ordinary case of heat exhaustion. There is another form, however, in which the heart does not seem to suffer principally, but in which there is collapse, with palsy of the vaso-motor system, with great fall of body temperature and marked general nervous symptoms.

The following is a case in point:

"A very powerful man, while working in an intensely hot, confined space, fell down suddenly without giving any warning, and was brought into the hospital. He was in a state of restless, delirious unconsciousness, incessantly muttering to himself, and when shaken or shouted at, responding only by a momentary grunt. The pulse was rapid, fluttering, and feeble. The surface of the body was covered with a very heavy sweat and exceedingly cold. The muscular relaxation was extreme. The facies was that of collapse, and the temperature, taken in the mouth, was 95.25° F."

The treatment of heat exhaustion is obvious from the symptoms. The indications being to stimulate the flagging circulation and warm the body by heat applied externally with an energy proportionate to the severity of the case. In mild cases stimulation with whisky will suffice; in the more severe, digitalis, ammonia, and atropia may be necessary.

II. *True Sunstroke, or Thermic Fever*, as it is called by Wood, is always caused by exposure to excessive heat.

As the body can cool itself much more rapidly by perspiration and its evaporation in a dry atmosphere, it is able to resist the influence of a dry, overheated air much better than where there is much moisture. It is for this reason that sunstroke is so much more infrequent upon high table-lands, or in the dry belt of our Texan prairies, than in the lowlands of India or upon our own sea-coast. Hence we find, during the very hot weather in New York, an increase in temperature, with corresponding increase in the humidity of the atmosphere, is followed by an increased number of cases of sunstroke.

Indoor workers in confined, moist factories, and especially in laundries and sugar refineries, are especially prone to be attacked.

At one time it was thought that exposure to the sun's direct rays was the chief cause of sunstroke, but there is now abundant clinical testimony to the effect that such exposure is not necessary, attacks, indeed, often coming on at night.

Although the immediate cause of the attack is excessive heat, there are certain conditions which act as predisposing causes, by lessening the powers of resistance of the system to the heat. The chief predisposing causes are race, excessive bodily fatigue, and intemperance.

Races which are least accustomed to a tropical climate are most apt to be attacked; thus, both in this country and in India, Europeans suffer more than the natives. No race, however, is absolutely exempt. Even the negro and the Hindoo are occasionally prostrated.

The general experience in the United States shows that habitual excess of alcohol very strongly predisposes to sunstroke. Cases of insolation in this latitude are generally seen by the physician after the stage of insensibility has been reached. In many cases this comes on very suddenly, but in others there are distinct prodromata, such as disinclination to exertion, dizziness, headache, confusion of ideas, oppression of breathing, and disturbance of special senses, especially of sense of sight.

A large number of cases reported by H. C. Wood, showed the following set of symptoms, which were quite constant:

Total insensibility was, as a rule, present, with, in rare instances, a talkative delirium, or, still more rarely, the patient could be partially roused by shouting.

Breathing was stertorous, and often accompanied by mucous rattles in the throat.

Face generally suffused, sometimes deeply cyanotic, as was the whole surface of body.

The eyes (conjunctivæ) were injected, pupils variable. Skin always intensely hot and generally dry, sometimes, however, covered with a profuse perspiration.

The intense burning heat of the skin, both as felt by the hand and recorded by the thermometer, was one of the most marked features of these cases. The temperature during life in most of these cases was from 108°–109° F., but it sometimes reached 112°.

The pulse is always very rapid; although at first it is often strong and full, later it may become irregular, thready, and intermittent.

The motor nervous system is profoundly affected; there is sometimes great restlessness, or partial spasms or general convulsions. Sometimes the motor system is paralyzed, the patient remaining motionless.

Hemorrhages into the skin or mucous membranes, evidencing broken-down blood, are sometimes present.

There is often a very peculiar odor about sunstroke cases, which to some physicians is quite distinctive.

Discharges from the bowels are often involuntary.

There is a form of insolation in which death results at once, and probably always by sudden arrest of heart action. This is rarely seen in civil life, but has been noticed among soldiers during battle, or at times when great exertion is being made, as during exhausting marches through hot, moist lowlands in India.

Post-mortem changes.—Owing to the excessive heat of the body, the temperature frequently rising after death, putrefactive changes are very rapid.

There is general venous congestion of all the organs.

The coagulability of the blood is impaired; it appears dark, often thin, sometimes grumous, feebly alkaline, or at times distinctly acid in reaction. Extravasations found in various parts of body and nervous system being due probably to the altered blood-crisis.

There are very many theories as to the causation of the phenomena of sunstroke. Perhaps the most probable is that of Wood, based on the theory of Letschenow. According to the latter, there is in the brain (Pons Varolii) a centre, whose function it is to inhibit the production of animal heat, and in the medulla, another part of the brain, another centre, probably vaso-motor, which regulates the dissipation of bodily heat. Wood, in an elaborate research, supports the truth of this theory, and points out that fever is due to a disturbance of these heat centres, so that more heat is produced than normal, and proportionately less thrown off. Now, supposing a man is placed in such an atmosphere that he is unable to get rid of the heat which his body is forming, the temperature of his body will rise, and he may suffer from a gradual thermic fever. If, early or late in this condition, the inhibitory heat-centre becomes exhausted by the effort which it has been making to control the formation of heat, or becomes paralyzed by the direct action of the excessive temperature already reached, then suddenly all tissues will begin to form heat with great rapidity, the body temperature will rise with a bound, and the man drops with some one of the forms of sunstroke.

If this theory be correct, says Wood, heat exhaustion with lowered temperature probably represents a sudden vaso-motor palsy, i.e., a condition in which the exhausting effects of the heat paralyzes the vaso-motor centres in the medulla, and not the inhibitory heat-centre, since experiments have shown that vaso-motor palsy increases enormously the loss of animal heat and diminishes its production.

In most cases of sunstroke death comes on gradually from arrest of respiration, which is probably due to direct paralysis of respiratory centre by excess of heat.

Allusion has already been made to cases of sudden death by cardiac arrest, which have especially been seen in India during a march or battle.

Diagnosis of insolation is generally easy. In distinguishing between simple heat exhaustion and true sunstroke the temperature is the best guide.

Prophylaxis against thermic fever consists in the observance of a few simple rules. If exposure to heat is imperative, the bodily health should be maintained by the avoidance of alcoholic or sexual excesses, and, as far as possible, of great mental or bodily fatigue. The diet should be simple, and the glandular apparatus of the skin, bowels, and kidneys kept active by the use of good fruit and water in abundance.

In mild cases of sunstroke the basis of treatment is the cold bath. It is customary here in New York, in hospital practice, to put the patient at once into a bath, and to reduce the temperature of same by addition of lumps of ice, the effect on the patient being carefully watched, and stimulants being given as indicated. Or the patient may be placed on a Kibbé cot, an ice cap applied to head, and the body sprinkled with cold water.

In severe acute cases of sunstroke, with very high range of temperature, it is essential that this should be reduced at once, and no time should be lost in waiting for the physician. As soon as a patient falls, he should be carried at once into the shade, his clothing removed, and cold affusions applied over chest and body. This must be done freely. In the larger cities the ambulances are often supplied during the "heated term" with ice and antipyrin, so that when the patient is reached no time need be lost in instituting proper treatment; many lives are doubtlessly saved by such prompt and efficient work. In using these various measures, such as the ice pack and cold bath, it must be remembered that the indication is the reduction of temperature, and the clinical thermometer affords the best guide to the effect of the treatment. Often little else is required. If, however, the period of insensibility has lasted too long before using these, consciousness may never return, even though the temperature fall to normal under treatment. These are very serious cases.

Sometimes after the temperature has been reduced in ordinary cases there is great tendency to relapse, and the same measures have to be repeated, the baths or some antipyretic drug being used daily perhaps for several days. Many persons who have been sunstruck suffer from after effects. In the mildest form there may be inability to bear heat without causing headache, dyspeptic symptoms, and failure of general vigor, with other indications of disturbed innervation. In other cases the symptoms are more

decided. Headache is generally prominent, and it may be almost continuous for weeks or months, though there are generally exacerbations. With this may be dizziness, loss of memory, and excessive irritability of temper.

One pathognomonic sign in the sequelæ of sunstroke is the effect of heat. The glare and heat of summer are, of course, the most trying, but usually even artificial heat is not well borne. It is not uncommon, indeed, for headache and severe general distress to be produced by entrance into a warm room even in winter.

SUOVETAURILIA, a Roman sacrifice, which was offered in nearly all cases of lustration and derived its name from the three animals of which it consisted, a boar (*sus*), a ram (*ovis*), and a bullock (*taurus*). In sacrifices to female deities, female animals were selected.

SUPERCARGO is an important officer in a merchant vessel, charged with the control of all her commercial transactions. The cargo is under his care, and he judges as to its disposal and replacement.

SUPEREROGATION, WORKS OF (Lat. *supererogata*, over and above things required), a class of works which, in the Roman Catholic system, are described as not absolutely required of each individual as conditions to his eternal salvation. Roman Catholics found this definition on the distinction between what they believe to be commanded and what they hold to be only counseled, for an example of which they appeal to the words of our Lord to the young man in Matthew xix. 21, which distinguish one class of works which are necessary in order to "enter into life," and a further class which must only be done if we "would be perfect." Roman Catholics do not profess to recognize in works of supererogation any distinctive essential quality by which they differ, whether in their physical or their moral entity, from other works, and in virtue of which, by their own nature, the individual may found upon them a personal claim to reward. For works of supererogation, as for all supernaturally good works, they hold that the assistance of God's grace is indispensably necessary; and they do not ascribe to them any merit, except that which arises from God's own free and gratuitous promise. In one word, the only distinctive characteristic of a work of supererogation lies in its not being supposed to be prescribed or commanded as absolutely necessary for the salvation of the individual, and its being done for the sake of greater perfection; and the doctrine which teaches the possibility of such works is, according to Catholics, a necessary consequence of the unequal fervor and unequal degrees of holiness which exist even in the class of the virtuous servants of God. A further consequence of this doctrine is that God may accept the superabundant works of one in atonement for the defective service of another; and hence, in the Catholic theory of indulgences (q.v.), along with what they regard as the infinite and inexhaustible treasure of the merits of our Lord, they also regard, although in a degree infinitely inferior, the superabundant merits of the saints as forming part of that "treasure of the church" which is applied in the form of indulgences.

SUPERFETATION, or the circumstance of two distinct conceptions occurring in the same woman at an interval of greater or less duration, so that two fetuses of different ages—the offspring possibly of different parents—may co-exist in the uterus, is a subject of great interest both in a scientific and in a medico-legal point of view. A couple of centuries ago, there was a universal belief in not only the possibility but the comparative frequency of this occurrence. Fifty years ago, it was as universally disbelieved; and now again (owing to the investigations of various inquirers, among whom Dr. Bonnar of Cupar deserves special mention), we are returning to the belief of our ancestors. The cases described as instances of superfetation may be arranged in three classes; but as will be presently seen, it is only to the cases of the third class that the term superfetation is truly applicable. The *first class* includes the numerous undisputed cases in which two mature children, bearing evidence, from their different colors, that they are the offspring of different parents, are born at the same time. In the slave states of America, it was by no means uncommon for a black woman to bear at the same time a black and a mulatto child—the former being the offspring of her black husband, and the latter of her white lover; and the converse has occasionally occurred—a white woman at the same time bearing a white and a mulatto child. There is no difficulty in accounting for these cases, which are examples of contemporaneous conception rather than true superfetation. The *second class* includes those cases in which a twin has been aborted, leaving its fellow undisturbed in the uterus, to be matured and born in due time, or in which twins have been produced at the same time, one of which was fully formed, while the other was small and apparently premature, from being "blighted" or arrested in its development at an early period. Cases of these kinds are by no means rare; but there is no reason for believing that the infants were conceived at different periods. The *third class* includes the cases in which a *mature* child has been born, and an *immature* fetus, the product of a different conception, has either been left in the womb until its period of maturation, or, if expelled along with the other, has presented no mark of wasting or of arrested development. "In a case of genuine superfetation."

says Dr. Bonnar, "a woman must bear two (or more) mature children, with an interval of weeks or months between the birth of each; or, if she part with the whole contents of the uterus at the first delivery, the difference of the ages of the fetuses, or the mature child and the fetus, as the case may be, must be unmistakable, and there must be the absence of all marks of blight of the latter, so as to leave no doubt that, had it remained in utero, it would have gone on to perfect maturity." Among the cases of superfetation that have been specially discussed by writers on midwifery and medical jurisprudence, are the following: (1) Velpeau quotes from the *Recueil de la Société de Médecine* the case of a woman named "Arles," who, in 1796, gave birth to a child at the full time, and five months afterward to another, which was also thought to be at the full time; (2) Dr. Maton, an eminent London physician, communicated to the college of physicians the case of Mrs. T——, an Italian lady, who was delivered of an apparently healthy and mature male child on Nov. 12, 1807, but which lived only nine days. On Feb. 2, 1808, or 82 days after the birth of the first, she was delivered of a second child, which likewise had every sign of being completely formed and mature. The following case, which, as Dr. Bonnar (in his *Critical Inquiry regarding Superfetation*, Edin. 1865) observes, "has been the principal battle-field of the advocates of superfetation and their opponents," and has given rise to more discussion than any other, is recorded by Dr. Desgrange of Lyons. Madame Villard had a miscarriage at seven months on May 20, 1779. In about a month thereafter she conceived again, and on Jan. 20, 1780, she brought forth a living child. No milk appeared in her breasts, the abdomen did not seem to diminish in size, and other symptoms which normally follow delivery were absent. The two surgeons who were in attendance being naturally puzzled, called in Dr. Desgrange, who declared, in opposition to their views, that there was still a child in the womb; and his opinion was confirmed by her being delivered of a living child on July 6, 1780, 167 days after the first birth. Dr. Bonnar has collected from *The Peerage* a number of cases of probable superfetation occurring in married life. Excluding a very few exceptional cases, he adopts Dr. William Hunter's view, that 210 days, or seven calendar months, is the minimum period of uterine life at which a child should be born in order to be reared, and he assumes that no prolific intercourse can take place until at least fourteen days after the first delivery.

SUPERIOR, city, port of entry, and co. seat of Douglas co., Wis.; on lake Superior, and the Chicago, St. Paul, Minneapolis, and Omaha, the Duluth and Winnipeg, the Duluth, South Shore, and Atlantic, and the Northern Pacific railroads; opposite Duluth, Minn. The city is locally divided into parts known as East, West, South, and Old Superior, but all are under one government. Superior contains a state normal school, two high schools, St. Francis, St. Mary, and the W. C. T. U. hospitals, public library, electric light and street railroad plants, waterworks supplied from lake Superior, excellent sewerage plant, national and state banks, and numerous churches. The city being laid out originally for a great commercial port and having a harbor that has been improved at a cost of over \$7,000,000 by the federal and city governments and private corporations, is well equipped for the position it occupies. There are numerous grain elevators, coal docks, flour mills, ship-yards for building whaleback steamers, the largest dry dock on the great lakes, and iron and steel works. The commercial receipts include large quantities of coal, lumber, iron, ore, cement, and salt, and the shipments comprise grain, flour, lumber, coal, copper, and the general products of the region tributary to the city. Pop. '90, 11,983.

SUPERIOR, LAKE, the largest body of fresh water in the world, is the highest and most western of the great lakes lying between West Canada and the United States. It is situated not far from the center of the North American continent. Its general form is nearly semi-lunar, the outer curve being towards the north. Greatest length from e. to w., 390 m.; greatest breadth, 160 m.; area, 31,420 sq. miles,—fully that of Ireland. The surface of the lake is about 600 ft. above the level of the sea, and its mean depth 1000 ft., so that its bottom is 400 ft. below the level of the sea. Its surface has an elevation of about 22 feet above that of lake Huron and lake Michigan. The greater portion of this rise is at the Sault Ste. Marie, a strong rapid about a mile in length, at the commencement of the river St. Mary, which transmits the waters of lake Superior to lake Huron.

Lake Superior, being situated very near the water-shed between Hudson Bay and the Mississippi, receives no rivers of importance, although hundreds of small rivers pour themselves into it. The largest are the St. Louis river, which falls into its western extremity at Fond du Lac, and is about 110 m. long; and the Neepigon river, on the n. side, which, with the lake of the same name, has a length of about 200 miles. One of the branches of the Mississippi in Minnesota approaches to within 20 m. of the western extremity of lake Superior; and a small lake near the head of the Albany river, of which the waters flow to Hudson Bay, is only 4 m. from a bay opposite the State islands on the northern shore, forming a route with little portage, which has long been used by the Hudson Bay company, for the conveyance of goods from lake Superior to the northern country.

The promontory Kee-wee-naw, near the middle of the s. side, projects far into the lake. The islands are not numerous, the largest being Isle Royale, 44 m. long.

The country around lake Superior is generally bold and hilly, with the exception of the peninsula lying between it and lake Michigan; but few of the hills rise more than 1000 ft. above the level of the lake, and most of them are far below this height. On the

southern shore, 100 m. w. of the Sault Ste. Marie, are the Pictured Rocks, cliffs of gray and red sandstone, from 100 to 300 ft. high, in many places presenting fantastic forms, and marked by numerous perpendicular stripes of red and yellow, from ferruginous waters trickling down the face of the rock.

The boundary between the United States and West Canada, starting from the outlet of the lake at the Sault Ste. Marie, sweeps toward the n., so as to include in the United States even the Isle Royale, which is only 13 m. from the British coast, and strikes inland from the mouth of Pigeon or Arrow river, on the n.w. shore.

The only obstacle to navigation between lake Huron and lake Superior is the Sault Ste. Marie, which is overcome by canals and locks on the U. S. and the Canadian sides. They are, perhaps, the finest canals in the world. The locks are admirably contrived, and the largest ships can pass through with ease. The trade has increased rapidly since the completion of the canals.

The water of lake Superior is remarkable for its coldness, purity, and transparency, although the affluents on both sides are either turbulent or deeply colored by vegetable matter from swamps and forests.

A rise or fall in the level of the water, amounting to several inches in a few hours, is frequently to be observed along the shore, and has been supposed to be due to a regular tide, but is probably caused by the wind. Fresh water being more easily moved by the wind than salt water, great waves arise in lake Superior with wonderful rapidity; and even in summer, large steamers are compelled to take shelter in some bay, or under the lee of an island. Owing to the low temperature of the water, compared with that of the air, in summer, fogs are prevalent, resting on the water at night, and vanishing an hour or two after sunrise.

Lake Superior never freezes over, but the bays are sealed up in winter, and a rim of ice extends to some distance all around the shore.

The rocks around the lake are very ancient, belonging principally to the Laurentian and Huronian systems of the Azoic series, overlaid in some places, especially on the s. side, with patches of the lower Silurian. The prevalent Laurentian rock is orthoclase gneiss. Among the Huronian rocks are greenstones, slates, conglomerates, quartzites, and limestones. The lower Silurian rocks are soft sandstones. There is everywhere much evidence of glacial action.

The Huronian rocks are well stored with useful minerals. The copper and iron mines of the s. side are celebrated for their extent and richness, and there is every reason to think that the mineral resources of the British side are equal to those of the American, although as yet comparatively undeveloped. The richest copper-mines are situated near Kee-wee-naw point. The metal occurs principally native, and sometimes in single masses of great size. One was met with in 1853, which measured about 40 ft. in length, and was calculated to weigh about 400 tons. Native silver is found associated with the native copper, and sometimes intimately mixed with it. A rich vein in an islet in Thunder Bay (British side) yielded in 1870-73 silver to the value of \$1,230,000. Gold has been found in small specks at Namainse on the British side. Lead ore occurs in some places. The beds of hematite, or red iron ore, at Marquette, on the s. side, are of wonderful extent. The ore is conveyed by rail and water to cities in the United States, where it is smelted.

SUPERPHOSPHATES. See PHOSPHORUS.

SUPERSTITION. The origin of this word has occasioned much controversy, as it is involved in the mystery of the ages, but it is generally accepted as a strictly Roman word, for which the Greek had no synonym. We owe to Cicero (q.v.) its true signification, which has recently been rescued from the oblivion which has obscured it for ages namely, "standing over," or "surviving," and thence it signifies something remaining after a change, by which it might possibly have been destroyed. Those who escaped in battle or survived death, were called *superstitēs*, *superstitiōs*, or survivors. Cicero says "they who prayed all day that their children might over-live them" were called *superstitiōs*. Lactantius objects to this derivation, but says the word gets its meaning from the worship of deceased parents and relations, by the *superstitēs* or survivors, or from men holding the memory of the dead in superstitious veneration. Thus Cicero and Lactantius agree in connecting the origin of the word with the relations between the dead and the living who *survive* them. Cicero gave it his sanction when he wished to consecrate the image of his dead daughter to the gods, whom he did not hesitate to affirm were men who had survived death. In any case, the word originated in some mysterious connection between the dead and the living, the deceased and those who survived, the world that is seen and the world that is unseen; whether it might be that it arose from the "Promise made to the Seed of the Woman," and it was considered a great misfortune to die childless, or to survive one's children; or that the death of one person might be influenced by the death of another. The word "survival," then, best defines "superstition," meaning the remainder or residue of something gone before, although it has long received a different signification, namely, that of being in excess, over-scrupulous, exact, and it cannot be denied that this secondary sense, did, from an early period, influence the acceptance of the term, until, at length, it superseded the primary sense.

and was received as the true germ and original idea of superstition. Being comprehended in the same word, this sense of scrupulosity, idle ceremony, and superfluous care, overestimating trifles, which underlies all superstitions, finally swallowed up its obscure and mysterious origin involved in the relations between the dead and the living. But the word "survivals" may be used in a broader sense than "superstitions," as the latter is practically confined to things appertaining to religion, while "survivals" may indicate habits, or expressions inexplicable by the light of our present advanced ideas, but easily explained by reference to similar customs or prejudices still to be found among distant tribes and mentioned by ancient writers. Thus a word which originally signified merely those religious delusions which "survived" the influence of advancing civilization came in process of time, by a kind of historic metonymy, to denote the brutalized ignorance, the unobservant credulity, and the unreasonable awe by which these errors were distinguished; and objects unworthy of reverence were accorded a kind of religious veneration, and the true God was worshipped through improper rites and ceremonies, and His divine will was announced by omens.

Until recently, wise men have only looked askance when the subject of superstitions was mentioned, but now in England, Germany, Bohemia, China, and America men of learning have set about collecting documents on this subject, as they now regard them as the wrecks of former beliefs over which centuries have spent their storms. "Survivals" have been aptly called "milestones on the way of culture." Many theologians unite in defining religion to be the feeling which falls upon man in the presence of the Unknown. Man naturally fears what he does not understand, the unknown may bring danger to him, and all the future is hidden in the unknown. Under strong excitement Man has personified the Unknown and that personification he sought to propitiate when he offered sacrifices to the shades of his ancestors and commanded the burial of their bodies that their spirits might rest in peace. ANIMISM (q.v.), in which all the powers of life and nature were attributed to the spirits of those who had gone before, constituted the lowest form of superstition; hence arose the feeling of veneration among the earliest savage tribes with which their ancestors were always regarded, and the facility with which hero-worship developed into a religion in the minds of the simple *pagani* (country folk), already alive to the fear inspired by the phenomena of nature and the grandeur of the elements. This first semblance of religion, gradually, by mere observation and experience, was converted into the belief in a superintending being long before Revelation had made known the benevolent system we have now. But, necessarily, the progress was gradual, and at every stage, the peoples, as they advanced in knowledge, were enabled to look back upon those barbarous sections who still lingered behind, called *superstites*, and to discern the remnants, *superstitia*, of that ignorance and fear from which the most degraded had not wholly emerged. The question arises whether any tribes have ever existed, destitute of a form of what may be called religion. If not, it might have been so much mixed up with superstition that those who criticise sharply and maintain that superstition is the reverse of religion, as well as morals, asserted that the country-folk practised SHAMANISM (q.v.) under the guise of religion.

Traces of superstition or prehistoric religion may still be found in every part of the world, in the heart of civilized Europe, where many of its crude and grotesque customs still practised are very similar to those of China, central Asia, dark Africa, and Australia. How can this prevalence of the same ideas be explained? Does it prove that communications between distant members of the human family were more frequent than we have always supposed, or that we have all sprung from a common stock? Or may we credit the fact that men have similar beliefs because they have similar minds? We know that Superstition took its rise very early in the world and soon spread itself all over the face of the earth, and few, very few, were there who were wholly free from it. The mischiefs it has produced are well known—gods of all sorts and kinds, sacrifices of beasts and men; rites, ceremonies, absurd tricks, and cruel torments, with every other thing which from all time has been falsely called by the name of religion, have arisen from hence. The doctrine of the divine Jesus was calculated to destroy its influence and cause religion to glow with a new light, but superstition soon found an entrance among Christians, and increased and remained in spite of the Reformation (q.v.) and the revival of letters, and even showed itself among those who rejoiced that they were free from the Papal yoke. The form which superstition has assumed throughout the dim ages of the past, before revelation of the true God arose, leaving hideous wrecks strewing its pathway, as it heralded the advance of civilization, were so many and so varied that the mind of the present day shrinks with horror at the contemplation. The belief in apparitions (q.v.), brownies (q.v.), elves (q.v.), fairies (q.v.), ghosts (q.v.), or spectres has prevailed in connection with supernaturalism from the earliest ages, and has not died out with the light of the nineteenth century. It arose with the dawn of the world, and has lived despite all persecution. In the same category may be mentioned the following subjects, to special articles on which reference is made: Amulet, Astrology, Augury, Auspices, Cabbala, Demoniacs, Demons, Divination, Evil Eye, Exorcism, Horoscopes, Incantation, Lycanthropia, Magic, Mandrake, Mascot, Necromancy, Oracle, Ordeal, Possession, Rhabdromancy, Seers, Sorcery, Sortilege, Talisman, White Lady, and Witchcraft.

Gradually there arose above the reverence for the spirits of the air and hero-worship an idolatry for the objects and phenomena of nature, and the Sun, Moon, and Stars gave rise to Zabism (q.v.) in some countries, Totemism (q.v.), Shamanism (q.v.), and Lamaism (q.v.). Folk-lore (q.v.) is a science of itself. During the middle ages, for centuries, thaumaturgy, or the study of the supernatural, was almost universally popular, and in every part of the world the magician and the sorcerer vied with the priest in the practice of their arts, until all the better qualities of the human mind were well-nigh suffocated with the noxious weeds. Many venture to affirm in their innocence that the days of superstition are past. How little do they know of what they affirm, concerning the belief, not only of the so-called uneducated class, but of those who it might be supposed from their station and education would rise above such influences. And this is true of the old-fashioned belief in ghosts, wizards, and uncanniness; which still prevails. To this fact the daily papers bear witness, when they publish the account of some wretched old woman being dragged before the judge, for pretending to tell fortunes with a dirty pack of cards, or the dregs of a teacup, and yet, with human inconsistency, the legislator permits the turf-touters to advertise their superstitions, and allows the wise man to cure warts, toothaches, and certain cattle-diseases by incantation. How common to find the rustic apply to the charmer to have his toothache cured, not understanding the well-known effect of a visit to the dentist upon the nerves. The rumor of a haunted house is a source of joy to a whole neighborhood, as it immediately becomes the centre of curiosity. And many times, in the opinion of the rustics, the ringing of the bells, or the fancied apparitions, are owing to the fact of the bones of a human body lying unburied in some part of the house, thus recalling even at the present day the old obligation of burial of ancestors, to assure peace. CHIROMANCY (q.v.), or the art of foretelling the future by the hand, is a science of antiquity recently revived in fashionable circles, and it retains all the superstitions attached to it in the past. All secrets are revealed by the lines in the palm of the hand, and besides, the thumb is given to Venus, the forefinger to Jove, the middle finger to Saturn, the ring finger to Sol and the little finger to Mercury. "Little finger tell me true," is a French proverb used by Molière (q.v.) in his *Malade Imaginaire*, when a French gentleman of renown wishes to question his little daughter respecting a young man who visits her elder sister and he says to her: "Be very careful there, because here is a little finger which knows everything and will tell me if you deceive." When the child has told him all she knows, he puts his finger to his ear, and says: "There is my little finger, yet which mutters something. Listen! He! Ah, ah! yes? Oh, oh! there is my little finger which tells me something that you have seen and that you have not told me." To which the child replies: "Ah, my papa, your little finger does not tell the truth!" But there are many other sciences besides Chiromancy. SCAPULAMANCY is still practised among the tribes of Central Africa and Asia. It is built on lines, but they are the cracks on the blade-bone of a shoulder of mutton. CAPNOMANCY foretells the future from the rising smoke, and by pyromancy it can be read from fire. ÆROMANCY augurs from the breeze and clouds, and hydromancy from the water. Even by the waves of the sea can be told the visions of the future. In ancient times the Spirit troubled the water, and the clew was found in the lines produced. If the Spirit was an evil one, all things were read backwards. Later, a ring was hung by a thread over a glass and shaken, and the message was given by the strokes on the glass; or three pebbles were thrown together in a well, and the future read from the figures caused by the widening circles. PALOMANCY is divination by fountains, into which loaves of bread, dice, etc., were thrown. At Palicorus, in Sicily, was a celebrated fountain, and Ino's, near Epidaurus, is well known in history. Among the Germans the rapids and eddies of running water were made to divine the future. CATOPTROMANCY foretold by means of mirrors a development of hydromancy, for the first mirror was the water. In one form a mirror was let down into a well, until it touched the water, and the answer was given by the reflection from both. In SCYPHOMANCY a drinking cup was used. When the foundations of Persepolis were laid there was found the cup of Djemscheed, full of the elixir of immortality, and in this cup the Persian told how the whole world was shown; and while it was possessed the Persian empire flourished. When Seringapatam was stormed Tippoo Sahib retired in the midst of the battle to consult his divining cup and from it he fled in terror to die in the breach. Sometimes a drop of oil was floated on the surface of a bumper, thus forming the mirror on which the images would appear. Sometimes the oil would give place to treacle in a cup, or ink in the hand, which formed a connecting link with crystallo-mancy in which the seeker gazed into a transparent body. From Catoptromancy the transition was easy to divination by crystals, glass, etc. CRYSTALLOMANCY is practised at the present time, and spheres and eggs of quartz and glass prepared for the purpose, can be seen in the shop windows. Rock crystal, however, is a modern innovation, as the favorite stone in the past was beryl. "There are certain formulas of prayer," says Aubrey, "to be used before they make the inspection, which they term a call; these calls are always to be used, as nothing will appear in the crystal without." ONOMANCY was used by the Greeks, and was a science that depended upon the number of vowels in a name. If the number was odd, something was the matter with the right side. A curious story is told of the Goth, Theodotus. When he was about beginning his fight with Rome, in order to discover the

result, he gave names to thirty pigs, half being Roman, half Gothic, and in three different styes he locked them up, five Romans and five Goths in each. When the styes were opened, all the Romans were alive with half their bristles off, but all the Goths were dead. The signification was clear—the Goths would be beaten, but the Romans would lose half their force. MYOMANCY made use of the sounds and damage done by rats. The great dictator, Fabius Maximus, resigned his dictatorship because the squeal of a mouse warned him to do so. And for a similar cause Cassius Flaminus threw up the command of the cavalry. The bite of a rat was fatal to success, but Cato was equal to the occasion, when he replied to a soldier who came to him in terror, saying a rat had gnawed his shoe: "Would it not have been strange if the shoe had gnawed the rat?" ORNITHOMANCY, which depended on the habits of animals, was a branch of augury which was much practised by the ancients, and consisted in waiting for the flight of a bird. A hawk betokened victory, an owl, misfortune. If the bird flew to the right hand it meant good fortune, if to the left, evil. The call of the bird was also ominous. If chickens came slowly to their feed and pecked the corn about, misfortune was in the wind, but if they rushed ravenously to the grains all would be well. In ELECTROMANCY a white cock played the chief part by pecking a grain of corn or wheat off certain letters, his choice spelling out the future. A somewhat similar method was by DACTYLOMANCY, where a round table was divided into spaces, each having a letter, and over it a wedding ring was hung by a thread, its swing giving the letter forming the message from the spirit world. AXINOMANCY was also dependent on the direction of the unseen force and was used for the detection of guilty parties. GYROMANCY detected the guilty party by causing an innocent boy to run round and round until he was giddy, and fell opposite the letters containing the name of the culprit. CARTOMANCY tells fortunes by the use of playing cards, COSCINOMANCY by a sieve which is hung and tells tales by turning, and ONYCOMANCY depends upon the spots on the finger nails. In CLEDONISMANCY the first words uttered by friends when meeting gave the necessary indication as to coming events. In CLIDOMANCY a key was tied to the Bible and hung on a maid's ring finger, the key being found to move when the guilty name was uttered. For GEOMANCY pebbles were used; while in LITHOMANCY a particular stone was taken, and it is not unlikely that ventriloquism was brought into action and that in GASTROMANCY "deep whispers came from corporeal depths." "When Saturn thought he was devouring Jupiter, he was merely chewing a *betulum*, which was a rounded stone which fell down as a globe of fire, and the terrified observer saw that it was guarded by a lion. A learned doctor picked it up and it proved a mine of wealth."

ALEUROMANCY was a test of innocence by means of a piece of bread or cheese an ounce in weight, cursed to kill if guilty, which the accused had to swallow; barley bread was preferred, as being more likely to choke. In RHABDOMANCY two staves were set up and talked to, until one or both, under the incantation fell down, the position giving the expected sign. In BELOMANCY arrows were drawn on which were the names of cities it was thought advisable to attack. In HARUSPICATION the victim was slain on the altar and the future read from the twist of his entrails. "If frogs by croaking," Cicero makes his Stoic say, "can give us signs to foretell the weather, why should there not be omens in the fibres of a victim's entrails?"

Among the Zulus of Africa, at the present day, the belief in magic and sorcery still reigns supreme, and its influence is utterly demoralizing. Wizards and witches may produce their enchantments from a foot-print, or from the impress of the body in sitting or lying upon the ground. The finger-nails and hair, when cut, must be carefully kept and buried. Each sorcerer pretends to get his communications directly from the spirit-world and delivers them in the form of riddles or dark parables. They have a potion in use among magicians, which, when taken, enables a man to influence another at a distance simply by willing. And this gives them immense power, together with the force of custom, so that, although their predictions may fail, thieves may go unpunished, rain may not fall, patients may die, the magicians still remain a sacred order, and every failure is explained away, and the fetters of custom continue unbroken. It is interesting to note that Africans never speak of a man as dead; and the same thing may be observed in Scotland; they say, "He is taken away," or "He is not here." If a man has a narrow escape from death, he says, "My father's soul saved me." Although they have a superstition about spirits inhabiting caverns, roofs of houses, and other places, yet their general belief is that the spirit, at death, goes directly up to the spirit-land. Ancestor worship is not only their religion, but they actually regulate their whole life by it. They have a class of spirits corresponding to the fairies and brownies of England and Scotland. Among the negroes of Washington there exists a superstition, that oftentimes, at midnight, there rushes through the streets a supernatural being formed like a man, having long, hook-like fingers and a poisonous breath. Whenever he turns and breathes upon a house where a child lies sick, the child is doomed to death before another night. The *night-doctor*, as he is called, is only ominous when seen not heard. It is a common thing for the negroes to get together and inquire of each other who has heard him, and some one is sure to assert that he or she heard the low, moaning, rushing sound, as he passed during his flight. Sometimes, at midnight, negroes who are in the street will suddenly stop,

turn their faces to the wall, and stand with their hands over their eyes, as they fancy they have heard him pass, and, if they turn, he will blow his murderous breath upon them. The superstition concerning the CHILD'S CAUL is very old, and came originally from the East, several words in Arabic being found to express it. The caul is a membrane found on some children, encompassing the head, when born. This is thought to be a good omen for the child itself, and in Scotland is believed to carry with it the gift of second sight. The vulgar opinion is, that whoever obtains it, by purchase, will be fortunate and escape danger. Hence it is often advertised for sale, the price being about twenty or thirty guineas. It is an infallible preservation against drowning, hence seamen often become the purchasers. The superstition was very prevalent in the Middle Ages, even in the church, and Chrysostom inveighs against it, in several of his papers. In France it is proverbial, *Etre né coiffé*, signifying, "born with a caul," indicated extreme good fortune.

The superstition concerning WELLS and FOUNTAINS is of the most remote antiquity. They were supposed to impart virtues of many kinds, and the implicit faith in them is not yet extinct. The devoted would spend hours in them, standing in water up to their chins, sending up their prayers, or performing a number of evolutions round the polygonal well. The bathing well of Whiteford had a large stone, two feet beneath the water, which received many a kiss from the faithful, who never failed, it is said, to obtain their desires, provided they were offered with faith. Scotland furnishes many instances of wells superstitiously believed to have the power of imparting health and blessing. Near the parish church of Kirkmichael, in the county of Banff, is mentioned a fountain over which a guardian angel, in the form of a fly, formerly presided, and love-sick maidens and sober matrons flocked there to watch the motions of the fly. A singular phase of this superstition was leaving shreds and bits of cloth around the well to receive the blessing; these could afterwards be removed for the cure of diseases. This custom was not confined to England and Scotland, it was also common on the continent. To such an extent was it carried, that it was forbidden by the sixteenth of the canons issued in 960 by Edgar, and it was also condemned by the canons of St. Anselm in 1102.

Among the popular superstitions which the civilization of modern times has not been able to obliterate, that of the DEATH WATCH still maintains its hold. It has long been credited with predicting a death in the house where it is heard. Investigation has shown that the monotonous raps are caused by a small insect belonging to the timber-boring tribe, which is not discernible, being of the same color as a tree. It is the signal of the male to the female, made by tapping its head against the wood, strokes from nine to eleven in number, and then a pause.

SUPERSTITIONS OF THE MOON. The moon, which was an ancient object of idolatry, has in later times become an article in the creed of superstition. The ancient Druids had their customary rites and ceremonies at the changes of the moon, and these have had great influence among the rustics. The custom of addressing the new moon for the purpose of getting information as to the future husband or wife is one of the commonest prevalent, as, for example :

"All hail to thee, moon, all hail to thee,
I prithee, good moon, declare to me
This night who my husband shall be."

A dream is expected to follow in which the future spouse will be revealed. The Man in the Moon is supposed to have originated in the ancient account given in the book of Numbers, XV. 36. of a man punished with death for gathering sticks on the Sabbath day. In Ritsin's *Ancient Songs* we read the Man in the Moon is represented leaning upon a fork, on which he carries a bush of thorn, because it was for picking a stake that he was punished. In *A Midsummer Night's Dream* the Man in the Moon is personated by Peter Quince, with his lantern the moon. The Man in the Moon is a source of wonder to all children, to whom he is shown in connection with the nursery rhyme, "The Man in the Moon came down too soon." Different countries have different legends to account for his presence there. One widely extended, and alluded to by many writers, says that a man, while traveling along on Sunday, with a bundle on his back, was met by a fairy who asked him why he worked on Sunday. He replied, "Sunday on earth or Monday in heaven, it is all one to me." "Then bear your bundle forever, and as you have no regard for Sunday on earth, yours shall be a perpetual Monday in heaven, and you shall travel for eternity in the Moon." There he remains to this day. In some legends he has a companion, a woman with her butterfly, who was transported thither because she made her butter on Sunday. The Scandinavian mythology relates the story of two children that the moon stole and carried up to heaven. They had been drawing water from a well in a bucket, which is seen in the Moon, suspended from a pole on their shoulders. This recalls the nursery rhyme of *Jack and Jill*. The fall of Jack and the subsequent fall of Jill, simply represent the vanishing of one moon spot after another. April is called the Moon of bright nights, May the Moon of leaves, June the Moon of Strawberries, September, of falling leaves, and November the Moon of Snow-shoes. Astolpho reckoned the Moon to be the great depository of misspent time, wasted wealth, broken vows, unanswered prayers, fruit-

less tears, abortive attempts, unfulfilled desires and intentions. Bribes, he tells us, were hung on gold and silver hooks; princes' favors were kept in bellows; wasted talent was stored away in urns; but every article duly labeled. The Buddhist legend places a man and a hare together in the Moon.

It is generally acknowledged that the Americans, as a class, are inclined to be superstitious; but a visit to the race-track reveals the fact that no part of the community submits more willingly to the impositions upon its credulity, than the gamblers of the turf. Cross-eyed men and women, black cats, and HOODOOS, in the shape of acquaintances, jockeys, owners, and bookmakers, all are objects of the gambler's suspicion for good or evil. Some believe that they are more successful in picking the right horse, if they wear some particular article of dress—a certain scarf-pin or umbrella. One successful "plunger," who has made a fortune of \$16,000 on a single race, pins his luck into his scarf, in the shape of a small gold horseshoe, and would not part with it for any money. Another believes his luck lies in a switch-like cane, much resembling the branch of an apple tree. A celebrated pugilist, who turned his attention to the turf, firmly believed in the wonderful winning powers of an old blue serge coat, contrasting strangely with his tasty clothing. A hunchback is believed to possess peculiar qualities, and many derive a comfortable income from the privilege accorded to gamblers of rubbing their shoulders, at twenty-five cents a piece. Every follower of the races firmly believes in a "Jonah," and there is always a considerable amount of dodging to avoid an encounter with any one looked upon as such. Dreams are regarded as infallible in their predictions with this class of people; many betting solely upon the horses indicated in their dreams. The superstitions of actors and actresses are well known. A celebrated singer will never go on the stage for an opera, without causing each person she meets, on leaving her dressing-room, to go through a curious performance. If it chances to be one of the actors, or even a super, whom she first encounters, she causes him to hold up his thumb in front of her, then placing her thumb on his, she turns her hand around, at the same time pressing downward. If the thumb upon which she presses is held firm, she is satisfied, but if it gives way, it is a sign she will break down during the performance. A brilliant young actress of New York looks upon a battered old silver spoon as her *MASCOT* (q.v.), because when discouraged by her lack of success, one morning, she picked it out of a refuse box, and immediately thereafter procured the engagement which was the success of her life.

LUCK OF HORSESHOES. The superstitious custom of nailing a horseshoe to the threshold of the door, is one of the most common that has extended to the present day. The shoe, to insure the highest luck, must be found after it has been cast from the horse, and is supposed to possess the magic influence of hindering the power of witches, who might otherwise enter the house and work their spells, bringing ill-luck to the inmates. Many of the houses in the West End of London have a horseshoe on the threshold, and in Monmouth Street alone, at one time, might be counted seventeen. Churches, even, were not exempt from the superstition, for in 1797, under the porch of the Stanfield church, might be seen a tile with a horseshoe upon it, and similar instances might be mentioned. The great Nelson (q.v.) being very superstitious had great faith in one which he had pinned to the mast of his ship, the *Victory*. At the present day the horseshoe is placed over the door.

The custom of throwing a shoe after persons newly married, or servants entering upon a situation, is believed to be efficacious in bringing good luck to them. It is a question whether it was originally thrown for luck only, as we find it stated in the Scriptures that it was necessary to receive a shoe when executing a contract, as an evidence or symbol of assenting or accepting, dominion or ownership; giving back the shoe indicated rejecting or resigning it. See passages in Deut. XXV. and Ruth. Probably throwing a shoe after a bride was a symbol of renunciation of dominion and authority over her by her father or guardian; and the receipt of the shoe by the bridegroom even if accidental, was an omen that the authority was thus transferred to him. Many old farmers imagine they can foretell the weather from the number of dark spots around the sharp keel of a GOOSE-BONE. The darker the spots the colder the weather is to be. It is very common when our ears tingle, or our cheeks burn, to say that some one is talking about us, and this is a conceit of great antiquity, since it is mentioned by Pliny (q.v.) as a superstitious notion, that a universal Mercury, or signifying genius, conducted sounds to his distant subjects, and taught them to hear by touch. The bleeding of the nose is also an ancient omen of illness or death. **SPITTING** was a charm against fascination among the Greeks and Romans, and in Naples, even at the present day, the traveler may see the native spit upon the ground or extend his fingers to imitate horns, if he or she meet a *jettatore*, or a person supposed to be capable of exerting the influence of the **EVIL-EYE** (q.v.). Pliny says it averted witchcraft and availed in giving a sure blow. Boys are often seen spitting upon their hands for luck, and boxers and fish-women have the same custom. The **SERPENT-CHARM** superstition still holds its own, and it is probably only an outcome of the evil-eye, which in mediæval Italy ranked almost as an article of faith. In the same country, poison-mongery early attained the perfection of an exact science. In Naples there were experts who could specify the day when a tincture, "*Aqua tefana*," repeated in a certain number of Joses, would cause

death. It will hardly be credited that thousands of people recently crowded a certain road in the village of Melling, near Ormskirk, England, to inspect a sycamore tree which had burst its bark, and the sap protruded in a shape resembling a man's head. Rumor spread abroad that it was the reappearance of Palmer, a noted criminal, who had come again, because he was buried without a coffin. Almost the same superstition repeated, of thousands of years ago.

The superstitions of the people whose homes are by the sea, have been handed down from generation to generation, until they have finally become a part of their lives. In the fishing villages along the New England shore, it is a common belief that a person lying ill cannot die except on the ebb of the tide. Two of the most celebrated haunted spots are the north-eastern coast of Block Island and St. Mary's Bay, near Cape Race, Newfoundland. Here ghosts of phantom ships which have been wrecked or burned are said to be seen, not only by the superstitious villagers but by men of standing from Boston and New York. J. G. Whittier (q.v.), in his *Tent on the Beach*, mentions "the terrible ghost of Palatine" seen on the Block Island Beach. The legend of the spectral fishing fleet of St. Mary's Bay is as recent as 1862, when a hundred smacks went down in storm-tossed waters, and their ghostly forms are often seen at night. There have been occasions when much excitement on the subject of religion has prevailed, and strange nervous disorders have developed themselves among the people, which have been interpreted as immediate visitings of the Holy Spirit. This interpretation was delusive and the belief in it is superstitious. A very recent instance of this has occurred among the Indians in the neighborhood of the Cheyenne River, in the United States which, taking its rise in the visions of their "seers," ended in a ghost-craze dance extending over a large territory, through many villages, and from one tribe to another. They spread the news of the second coming of Christ and affected the Christian as well as the pagan Indians. Similar excitements or crazes have been noted at different periods among the North American Indians and also among the negroes, as well as in Siberia and various parts of Europe.

In the days of Pliny (although he loses no opportunity of laughing at the superstition) the Magi ascribed extraordinary supernatural properties to GEMS and to various figures engraved upon them. As civilization declined these notions came more and more into vogue, so that even a learned physician, Alexander of Tralles, recommended the wearing of the intaglio of Hercules strangling the Nemean lion, as a charm against the colic, and such intaglio do occur inscribed with four K's, to make assurance doubly sure. Gnostic stones frequently present inscriptions specifying the part of the body they were intended to protect from malignant influences. These "stones of virtue" were believed to have been engraved in the "times of the Israelites," a notion no doubt grounded upon the Hebrew words so frequent on the Gnostic intaglio. It was believed that stones having a form, derived a virtue from being cut into a special form and that they were likewise subject to the universal influence of the planets. By the engraving upon a gem its virtue was directed to a certain determinate effect, hence its influence was strengthened; and to be effective it was done under certain circumstances, and at a certain hour when the planet was strongest. The Diamond has the virtue of resisting all poisons, yet if taken inwardly is itself a deadly poison. It baffles magic arts, dispels vain fears, and gives success in lawsuits. The Chalcedony, if blest and tied around the neck, cures a lunatic; moreover, he that wears it will be drowned or tempest-tossed. It also makes the wearer beautiful, faithful, strong, and successful in all things. Aristotle says that an Emerald hung from the neck, or worn on the finger, protects against danger from the falling sickness. It is very highly approved in all kinds of divination; in every business, if worn it increases its owner's importance both in presence and in speech. A Sard of the weight of twenty grains of barley, if hung around the neck or worn on the finger, will guard the wearer against terrible dreams, and he shall have no fear of incantations or witchcraft, and shall be beloved by women. The Beryl is a large transparent stone. Upon it should be engraved a lobster and under its legs a raven; put under the gem a vervain leaf enclosed in a little gold plate. It being consecrated and worn makes the wearer conqueror of all bad things and gives protection against all diseases of the eyes. It dispels pains of the liver, and cures stoppage of breath, and the wearer shall be victorious in battle. The Balas Ruby was believed to repress vain and lascivious thoughts, appease quarrels between friends, and give health of body. Its powder, taken in water, cured diseases of the eyes and pains in the liver. If the four corners of a house, orchard, or vineyard were touched with this gem, they were safe from lightning, storm, or blight. The Opal was proof against all diseases of the eyes and preserved and strengthened the sight. Magically, it had the power of drawing all other gems to itself, and bestowed upon the wearer the qualities granted by Nature for its own purpose, for it penetrated all souls and dazzled all eyes. At the present time it is believed to bring ill luck to the wearer. The Coral defended against the scorpion and asp and guarded mankind on toilsome journeys. Amber and jet were preservatives against all complaints of the throat. If placed on the left breast of one's wife, they would force her to confess all the naughty things she had done. The Topaz if thrown into boiling water cooled it immediately, hence the gem cooled lust, calmed madness, augmented wealth, averted sudden deaths, and found favor with the great. The Turquoise guarded the horseman and averted all accidents. The enumeration of various supersti-

tions might be continued, ad infinitum, but it is sufficient to mention some instances of eminent men who have placed on record their belief in magic, omens, dreams, etc., and the results to which a pursuit of these superstitions has led, some of them very important: The dæmon of Socrates was a preceptor, or monitor, who gave him counsel and assistance in all concerns and actions of his life. Plutarch, Apuleius, and Cicero, all composed separate treatises in reference to the genius or dæmon which Socrates claimed to be his guide. Alexander became terrified at the sight of blood appearing inside the soldiers' bread during the siege of Tyre in 332 B.C. The seer who was consulted in reference to the event, happily foresaw in the crimson flowing from the soldiers' food a happy issue for the Macedonian king. A proclamation was issued, the incident fully narrated, and, nerved by the happy augury, the soldiers went to victory, and Tyre was vanquished. Luther believed in witches, and claimed to have hurled his inkstand at the Devil, and to have hit him, at which his Satanic majesty hastily fled his presence. Louis XIII. of France made a Franciscan monk his grand almoner, because he was promised a hundred years' reign. Even Archbishop Laud, with all his learning, was not free from the superstitions of the age. He noted down his dreams and various casual circumstances, as omens, to such a degree that a prominent writer in a leading Review of the period designated him as a "ridiculous old bigot," "forgetting the vices of his heart in the abject imbecility of his intellect." In Addison's (q.v.) *Spectator*, this sentence is found: "When I consider whether there are such persons as witches, my mind is divided; I believe in general that there is such a thing as witchcraft, but can give no credit to any particular instance of it." Mohammed was a fatalist. In the 11th century there were several instances of the alarming spectacle of the "Bleeding Host," and bleeding and bloody bread, as well as bewitched bloody milk, gave simple folk a scare.

In 1264, and again in 1383, drops of blood were found on the holy sacrament while it reposed on the altar. In 1510-38 Jews were burned, because, at it was claimed, they had tortured the consecrated host until it bled. The proof was the appearance of the blood. The bloody sight was witnessed again in 1824 on the river Moselle; and it was not until the year 1848, that a learned chemist, Ehrenberg (q.v.), declared on the authority of his microscope, that the red stains found on the bread, cheese, potatoes, and even on the consecrated host, were merely due to countless insects, microscopically small. In the inhuman burning of the Jews already mentioned, there was no scientific Ehrenberg to show their superstitious butchers that what they called a proof of the consecrated wafer being tortured until it bled was merely due to an aggregation of microscopic insects of a deep red color. Napoleon Bonaparte believed implicitly in his "Star of Destiny." Some of the results of following superstitious beliefs are remarkable: Roger Bacon stumbled on the composition of gunpowder; Gebir discovered many properties of acids; Van Helmont was so wonderfully successful in his cures as to attract the attention of the Inquisition, the members of which attributed his work to the Devil, nevertheless his discoveries in science, as well as the discoveries of Dr. Glauber, of Amsterdam, whose name is associated with a medicinal compound of world-wide reputation, have greatly benefited the world. The alchemist was too frequently the victim of a false idea, a fetishism. He was a slave of superstition; he worshiped science, the conqueror of power, but he often stumbled upon remarkable results. While alchemy and all its belongings may have dealt largely in a hopeless imposture, there was yet an immense resultant good.

SUPERTONIC, in music, the note which, in the diatonic scale, is next above the tonic or keynote, and forms with it the interval of the second, as D in the key of C major.

SUPPÉ, FRANZ VON, composer, b. in Dalmatia, April 18, 1820. He was sent by his father to study philosophy at the University of Padua, and studied music, which he chose for a profession. In Vienna he became the pupil of Sechter and Seyfried, and remaining there was kapellmeister of several theatres. Von Suppé composed a large number of operas, the most popular of which are: *Poet and Peasant*; *Pique Dame*, 1864; *Futinitza*, Vienna, 1876; *Boccaccio*, 1879; *Donna Trianita*, 1880; and *Bellman*, 1887; also overtures, quartets, and songs. He died in 1895.

SUPPLE JACK, a name given in the southern parts of the United States of America to the *berchemia volubilis*, a twining shrub of the natural order *rhamnaceæ*, which is found as far n. as Virginia. It has oval leaves, small flowers, and violet-colored berries. It abounds in the Dismal Swamp and in similar situations, and ascends to the tops of the highest trees. The genus *berchemia* contains a number of species of twining shrubs, natives of warm climates in different parts of the world. The name Supple Jack is also given in the West Indies and tropical America to *serjania* (or *seriana*) *tritermata*, a shrub of the natural order *sapindaceæ*, with a long, flexile, woody stem, which climbs to the tops of the highest trees, and is used for walking-sticks. It has poisonous properties, and is employed for stupefying fish.

SUPPORTERS, in heraldry, figures placed on each side of an armorial shield, as it were to support it. They seem to have been, in their origin, a purely decorative invention of mediæval seal-engravers, often, however, bearing allusion to the arms or descent of the bearer; but in the course of time, their use came to be regulated by authority, and they were considered indicative that the bearer was the head of a family of eminence.

or distinction. The most usual supporters are animals, real or fabulous; but men in armor are also frequent, and savages (q.v.), or naked men, often represented with clubs, and wreathed about the head and middle. There are occasional but rare instances of inanimate supporters. On early seals, a single supporter is not unfrequent, and instances are particularly common of the escutcheon being placed on the breast of an eagle displayed. The common rule, however, has been to have a supporter on each side of the shield.

SUPPOSITORY. Solid medicated bodies intended to be introduced into the rectum, either for the purpose of causing evacuation of the bowels by irritating the mucous membrane of the rectum, or of producing a specific effect on the neighboring parts. Their form is various, the spherical being preferable when the bulk is small. They are of such a consistence as to retain their shape, and at the same time soft enough to prevent injury to the walls of the rectum. For laxative purposes the suppository may be from one to three inches in length and the size of a candle. Where it is desired to have it retained for some time in the rectum, a smaller size is used, and the irritative influence of distension avoided. Soap is often employed, and solidified molasses (molasses candy) is frequently used with most beneficial results. The drugs used in the manufacture of suppositories depends upon the requirements of the case. Carboic acid, tannic acid, aloes, asafœtida, belladonna, mercury, morphia, soap, opium, lead and opium, all enter into the composition, as the exigencies of the case demand.

SUPPRESSIO VERI. Lat., a suppression of the truth. See **SUGGESTIO FALSI**.

SUPPURATION is a morbid process which gives rise to the formation of pus (q.v.), which, as is well known, is one of the commonest products of inflammation. There are two doctrines as to the origin of pus. The opinion universally adopted till very recently was, that it was formed from an excessive exudation of the fluid portions of the blood through the walls of the capillaries; in which exudation, under certain conditions, pus-cells were developed. This view is now rejected for the doctrine of Virchow, the eminent professor of pathology at Berlin, who maintains that pus-cells are generated from the corpuscles of areolar tissue, which he supposes to permeate nearly every portion of the body. Pus, according to Virchow, is a young tissue in which, amid the rapid development of cells, all solid intercellular substance is gradually dissolved. A single cell of areola or connective tissue may, in an extremely short space of time, produce some dozen of puss-cells; but the result is of no service to the body, suppuration being, to use his own words, "a pure process of luxuriation, by means of which superfluous parts are produced, which do not acquire that degree of consolidation or permanent connection with one another, and with the neighboring parts, which is necessary for the existence of the body." There are two different modes of pus-formation, according as the pus proceeds from epithelium (q.v.) or from connective tissue (see **CELLULAR TISSUE**). When puss is formed from epithelium, it is produced without any considerable loss of substance, and without ulceration; but when it is formed from connective tissue, ulceration must always exist. The mucous membranes vary in their power of forming pus. A mucous membrane, according to Virchow, is the more qualified to produce pus without ulceration the more completely its epithelium is stratified, those with a single layer of epithelium being less adapted for the production of pus. Thus the intestinal mucous membrane scarcely ever produces pus without ulceration; while other mucous membranes, containing several strata of cells, are capable of secreting enormous quantities of this fluid without the slightest ulceration (as, for example, the arethral mucous membrane in gonorrhea).

The above cases of suppuration occur on free or exposed surfaces, and are unaccompanied with loss of tissue. Deep-seated pus-formation takes place only in connective tissue. The first stage of formation consists in an enlargement of the normal cells, and a division and excessive and rapid multiplication of their nuclei. This is soon followed by division of the cells themselves, and their conversion into true pus-cells. If this process takes place beneath a surface which does not participate in the morbid change, or which is capable of resisting it for a time, an *abscess* is formed; whereas, when pus-cells are poured forth from an exposed surface, we have an *ulcer*.

Although suppuration is a morbid process, it often accompanies processes of a beneficial tendency (such as granulation), and frequently takes the place of other far more morbid processes. It further affords a mechanical means of removing foreign bodies, such as thorns, splinters of glass, etc., from soft parts into which they may have been driven; and it is possible (as some pathologists believe) that the formation of abscesses may sometimes serve to eliminate morbid matters from the system.

SUPRALAPSARIAN (Lat. *supra*, before, *lapsus*, the fall), the name given to the school of divines which maintains that God's absolute decree of election and reprobation is antecedent to his foresight of the fall of Adam, and irrespective of it. See **SUBLAPSARIAN**.

SUPRA-RE'NAL CAPSULES AND THEIR DISEASES. The supra-renal capsules are two small, flattened, glandular bodies of a yellowish color, situated, as their name implies, immediately in front of the upper end of each kidney. In weight they vary from one to two drams. They belong to the class of ductless glands, and on making a perpendicular section, each gland is seen (like the kidney) to consist of cortical and medullary substance. The blood-vessels and nerves of the glands are exceedingly numerous. Of late

years much attention has been drawn to the diseases of these organs from the observation of the late Dr. Addison (of Guy's hospital), that such cases are frequently associated with the deposition of pigment in the skin, causing it to assume a deep bronze color. The following definition of *Addison's disease*, or *supra-renal melasma*, or *bronzed skin disease*, embracing all the most important points in its natural history, is given by Dr. Aitken: "A morbid state which establishes itself with extreme insidiousness, whose characteristic features are anæmia, general languor and debility, and extreme prostration, expressed by loss of muscular power, weakness of pulse, remarkable feebleness of the heart's action, breathlessness upon slight exertion, dimness of sight, functional weakness and irritability of the stomach, and a peculiar uniform discoloration of the skin, which becomes of a brownish olive-green hue, like that of a mulatto, occurring in connection with a certain diseased condition of the supra-renal capsules. The progress of the disease is very slow, extending on an average over one year and a half, but may be prolonged over four or five. The tendency to death is by asthenia, the heart becoming utterly powerless, as if its natural stimulus—the blood—had ceased to act."

SUPREMACY, ROYAL. The term supremacy is, in politics, chiefly used with regard to authority in matters ecclesiastical. From the time of Pope Gelasius (494 A.D.) to the reformation, the pope exercised a very extensive authority, judicial, legislative, and executive, over all the churches of western Europe, somewhat undefined in its limits, varying in different countries and at different periods; which continues to be more or less recognized in all countries whose inhabitants are in communion with the church of Rome. At the English reformation, the papal supremacy was abolished, and act 26 Henry VIII. c. 1, declared the king and his successors to be the "only supreme head on earth of the church of England." A curious document was at the same time drawn up by the government, in which, to avoid misconception, it was explained that the recognition of this headship of the church implies only that the king should have such power as of right appertaineth to a king by the law of God, and that he should not take any spiritual power from spiritual ministers, or pretend to "take any power from the successors of the apostles that was given them by God." In 1535, the same year in which this act was passed, John Fisher, Bishop of Rochester, sir Thomas More, and others were beheaded for denying the king's supremacy; and in 1578, John Nelson, a priest, and Sherwood, a young layman, suffered the punishment of death for the same offense. The assumption by Henry VIII. of the title of "head of the church," notwithstanding the explanation alluded to, was much commented on; and on the accession of Elizabeth, it was thought prudent, while again claiming the supremacy in all causes, as well ecclesiastical as civil, to keep that designation in the background. By successive statutes, the oath of supremacy was appointed to be taken by the holders of public offices along with the oath of allegiance and of abjuration, and these three oaths were consolidated into one by 21 and 22 Vict. c. 48. The subject of oaths was, however, revised by the legislature in 1868 and 1871; and a new short oath of allegiance, in which the royal supremacy in matters ecclesiastical is not in express words specified, was substituted for the oath previously imposed upon members of both houses of parliament. See OATH.

SUPREME COURT. See JUDICIARY IN THE UNITED STATES.

SURABAYA, a leading sea-port of Java, and capital of a residency, is situated on the Kali Mās mouth of the river Kediri, near the strait of Madura, and on the Surakarta-Probolingan railway, in 7° 14' s. lat., and 112° 44' e. long. The population of the city and suburbs is about 110,000. The European town is on the w. bank, 5 bridges connecting it with the Chinese and Javan quarters on the east. It has a fine harbor guarded by two forts, a naval arsenal, a mint, numerous foundries, sugar refineries, and manufacturing of machinery, furniture, &c. Pop. '94, 148,199, including about 7000 Europeans. The residency of Surabaya comprises an extensive tract of fertile land in the n.e. of Java and the island of Madura. Rice, coffee, sugar, indigo, cotton, tobacco, and cocoanuts are extensively cultivated. Pop. of residency, '91, 2,005,005.

SURAFEND, a town in Palestine, 10 miles s.w. of Sidon, claimed to be the place where Elijah raised the widow's son from the dead. It was in ancient days celebrated for its wine.

SURAKARTA, a residency of Java, s.e. from Samarang, with an area of 2188 sq. m.; population in 1891, 1,163,305, of whom 2658 were Europeans and 8111 were Chinese. The country for the most part is mountainous, but nowhere do the mountains rise to a great height, the highest peaks being the Lawu on the east coast and Merbabu and Merapi on the west coast. The chief river of the residency is the Solo. The land is well watered and fertile, producing rice, maize, sugar, coffee, tea, indigo, tobacco, cacao, pepper, vanilla, and tropical fruits. Nominally the government is in the hands of a native chief known as the emperor of Surakarta, but he has surrendered his rights to the Dutch in return for important concessions. The Dutch maintain a resident at the capital.

Surakarta, the capital of the empire, and seat of the residency, lies on the left bank of the Solo, in 7° 31' 30" s. lat. and 110° 46' 7" e. long., covers a large space, and had in 1894 a population of 101,987, including about 1200 Europeans and 4090 Chinese. Many princes and nobles have their palaces in Surakarta; that of the emperor is of great extent and splendor. North-east from the royal parks lies the European town, in front of which, surrounded by the parade ground, and commanding the palace, is a square fort, with

broad canal and drawbridges at the four corners, and mounted with heavy artillery. It has railway connections with Surabaya, Samarang, and Batavia.

SURAT (Sans. *Saurashtra*, good country), a large but declining city of British India, capital of a district of the same name, 150 m. n. of Bombay, on the Ahmedabad-Bombay railway, and about 17 m. from the mouth of the Tapti, in the gulf of Cambay. It is 6 m. in circumference, and it is surrounded on the landward side by a brick wall. It has numerous mosques, several Hindu and Parsee temples, an Anglican, Portuguese-Catholic, and Armenian church. The palace of the pensioned Nabob of Surat, a high school, two hospitals, and, in 1891, a population of 109,229, inclusive of a large garrison. Its harbor, Suwalli, at the mouth of the Tapti, owing to a sand-bar, affords entry only to small vessels, and accordingly the commerce of Surat, which was once an important commercial center, has been steadily diverted to Bombay. It still exports a considerable quantity of silk and cotton fabrics. Surat is said to have contained — but this is probably an exaggeration — 800,000 inhabitants at the close of the 18th c., about which time its markets were crowded with the costliest wares, brought by merchants from the remotest countries. Surat is a place of considerable military strength, and the residence of a British military commandant and other dignitaries.

Surat was long thought to be one of the most ancient cities of Hindustan, but this opinion is now abandoned, and it is believed to have been a mere fishing-village as late as the 13th century. It first rose into importance as the spot whence the Mohammedans of Hindustan embarked on their religious voyage to Mecca. Surat was sacked in 1512 by the Portuguese soon after their arrival in India. In 1612 an English force arrived here in two vessels, under the command of Capt. Best, who defeated the Portuguese, and obtained a *firmān* from the Mogul emperor, authorizing the residence of a British minister. The Dutch trade with Surat commenced in 1617, when a Dutch factory was established. A French factory was founded in 1668. In the course of time, the English influence began to predominate. In 1759 the castle and fleet were made over to them; and from the year 1800 the government of the settlement has been entirely vested in their hands.

SURBASE. See PEDESTAL.

SURD. See IRRATIONAL NUMBERS.

SURETY. See GUARANTY.

SURFACE GRUB, the caterpillar of the *great yellow underwing moth* (*triphaena promuba*), a pretty large moth, with the upper wings deep brown or pale tawny, the under wings bright orange with a black border. This moth abounds in hay-fields in Britain at the season of haymaking. The caterpillar, when full grown, is nearly an inch and a half long, pale green with a tinge of brown, dotted with black, three pale lines down the back, and seven black spots on the inside of each of the two outer ones. It often does great mischief to the roots of cabbages and turnips, and also devours the roots of grass.

SURF DUCK, or **SURF SCOTER**, *Oidemia perspicillata*, a species of scoter extremely plentiful on the coasts of Labrador, Hudson's bay, and other very northern parts of America, from which great numbers migrate southward in winter. It is a rare visitant of the coasts of Britain and other parts of Europe. In size it is about equal to the mallard. The plumage is black, except two patches of white on the head and back of the neck. It is never seen on lakes or rivers, but only on the sea-coast. It dives so quickly that it is very difficult to shoot except when on the wing. Its flesh is rank, and has a fishy taste.

SURGEON, ARMY AND NAVY. An appointment to the medical corps of the army or navy is made only after a satisfactory examination, conducted by at least three medical officers, appointed for the purpose by the sec. of war. The candidate must be a graduate of a medical college, and be between the ages of 21 and 28 years for the army, and 21 and 26 for the navy. A surgeon in the army has the rank of major, and is required to have been an assistant surgeon at least five years. A surgeon in the navy has the rank of lieutenant, and must have been an assistant surgeon for two years. The assistant surgeons of the army and navy have respectively the rank of lieutenant and ensign.

SURGEONS, COLLEGE OF. The present "Royal College of Surgeons of England" dates its origin from the year 1460-61, when Edward IV. "did, at the supplication of the freemen of the mystery of barbers of the city of London using the mystery or faculty of surgery, grant to them that the said mystery, and all the men of the same mystery of the said city, should be one body and perpetual community." In 1500, four masters in surgery were appointed, under the title of "Magistri sive Gubernatores mistere Barbitonsorum et Sirurgicorum" (*sic*), and six years after this date the barber-surgeons of Edinburgh were incorporated by a charter from James IV. Although the original charter granted to the company of barbers of London was confirmed by several succeeding kings, many persons practiced surgery independently, and apparently in defiance of the company; and in order to check unqualified persons, it was enacted in the 3d year of Henry VIII. (1511) "that no person within the city of London, or within seven miles of the same, shall take upon him to exercise or occupy as a physician or surgeon except he be first examined, approved, and admitted by the bishop of London, or by the dean of St. Paul's, calling to him four doctors of physic, and for surgery other expert persons in that faculty." Hence arose a company called the surgeons of London. In

the 32d year of Henry VIII. (1540), the company of barbers of London and the company of surgeons of London were united "by the name of the masters or governors of the mystery and commonalty of the barbers and surgeons of London." It was not till the 18th year of George II. (1745) that the surgeons of London were by act of parliament separated from the barbers of London, and made a distinct corporation under the name of "The Master, Governors, and Commonalty of the Art and Science of Surgery of London." In the 40th year of George III. (1800), this company was dissolved, and replaced with their former and additional privileges by "The Royal College of Surgeons of London." A new charter was granted to the college in the 7th year of Victoria (1843), in which it is declared "that it is expedient to create a new class of members, to be called fellows," and "that from henceforth the corporate name or style of the said college shall be THE ROYAL COLLEGE OF SURGEONS OF ENGLAND." Power was given to the council to elect not less than 250, nor more than 300, members of the college to be fellows. These "first fellows" were mainly elected from the London and provincial hospital surgeons. Other fellows might subsequently be elected from the members, "after having complied with such rules and regulations as shall be considered expedient, and after having passed a special examination." Those who are admitted to the fellowship by examination are distinguished in the college calendar by the letters *Ex* being prefixed to their name. By an addition to the charter, obtained in 1852, power was given to the council, subject to certain regulations, to appoint members of 15 years' standing to the fellowship without examination. The college was likewise empowered to test the fitness of persons to practice midwifery and to grant certificates of such fitness; and in 1859 it was similarly authorized to test the fitness of persons to practice as dentists, and to grant certificates of such fitness.

The government of the college is vested in a council of twenty-four persons, including one president and two vice-presidents; and none but fellows of 14 years' standing are eligible as members of council. Three members of council go out annually by rotation, and the vacancies are filled up on the first Thursday of July. There is a board and a court of examiners, each consisting of ten members, including a chairman at the former, and a president at the latter; and as the examiners, who receive large emoluments (the fees to the court of examiners for the professional examination of members for the year ending June 24, 1878, were £10,110 15s.), are elected by the council, whose remuneration is slight, a position in the council is eagerly sought for as a stepping-stone to an examinership. Besides the court of examiners, there are special boards of examiners in midwifery, in dental surgery, and in classics, mathematics, and French for the preliminary membership and fellowship examination. There are four professorships in connection with the college—viz., that of human anatomy and surgery, the Hunterian professorship of comparative anatomy and physiology, the chair of surgery and pathology, and that of dermatology. A Hunterian orator is appointed every second year. The college sends a representative to the general council of education and registration. A candidate for the membership of the college is required to pass a preliminary examination in the usual branches of a liberal education. The fee for the anatomical examination is £5 5s., and that for the surgical, or pass-examination, is £16 15s., making a total of £22. The fellowship fee is an additional 10 guineas. For details, see the *Calendar of the Royal College of Surgeons of England*.

The museum of the college of surgeons is incomparably the finest museum of its kind in the United Kingdom. The Hunterian collection (see HUNTER, JOHN), which forms its basis, was purchased by a parliamentary vote of £15,000, and presented to the college in 1799. The edifice in Lincoln's Inn Fields (the germ of the present pile of buildings) was completed in 1813. The Hunterian collection was estimated to consist of 13,682 specimens; the total number of specimens was recently reckoned at above 40,000. The library contains 36,000 volumes. Both the museum and library are readily accessible to visitors.

SURGEONS OF EDINBURGH. ROYAL COLLEGE OF, was originally an association of those professing "surregerie and barbour-craft," who obtained their first civic charter in 1504, and had it confirmed by James IV. next year. About 1589 began the custom of granting leave to barbers to practice their profession, without admitting them to the full freedom of the incorporation. For a century and a half the members of the craft were sole teachers and almost sole professors of the surgical art in Edinburgh, and contrived to hold their own against the physicians, who, both before and after their incorporation as a royal college in 1681, made efforts to secure authority over the surgeons. In 1637 the surgeons granted the apothecaries a civil status in alliance with themselves; the nominal connection with the barbers was dissolved in 1732. A patent of 1694 settled the relations between the surgeons and the physicians, making amicable terms possible; and in 1778 the surgeons became formally a royal college too. Nevertheless they remained, much against their will, one of the incorporations of Edinburgh, till the act of 1851 dissolved what survived of their civic rights, and set the college free from the galling control of the town council. The college, which in 1881 had more than 450 fellows, sanctions the lectures of a staff of its own members as qualifying for examination candidates for its diploma of licentiate, and appoints a board of examiners. This examination is now usually taken in connection with that for the diploma of the college of physicians.

SURGERY. The art of surgery came into existence ages before those who practised it gave it a name. When finally the Greek words *cheir*, "the hand," *ergon*, "work," signifying the manual interference by means of instruments or otherwise, in cases of bodily injury, were combined to form the word *chirurgion* or surgeon, the art was already old, and the wisest of the Egyptians were familiar with operations which we consider important to-day. But surgery has no proper history previous to the advent of the great master and teacher, Hippocrates, whose name will occupy a position of honor forever in the annals of medicine. The sacred Scriptures furnish records of operations, but these referred more particularly to religious rites; such, for instance, as the operation of circumcision performed on Abraham when he was ninety years of age, about 1897 years before the Christian era. This operation was usually performed with sharp Ethiopian stones. "Then Zipporah took a sharp stone and cut off the foreskin of her son and cast it at Moses' feet." This method of operation was used by the Ethiopians as late as the sixteenth century. The idea that the ancient Egyptians, learned in every department of life, and yet deriving no information from frequent operations of evisceration in embalming, is untenable. The remains of mummies prove very conclusively that the science of bandaging, not the least important in the art of surgery, was well understood by them. The healing art among the ancient Egyptians had advanced to a very high degree in the time of Herodotus. Twelve hundred and fifty years before the Christian era, Æsculapius was worshipped as the divine physician. The offices of priest and physician were at this time combined. Even in the early history of the Christian era this state of affairs existed, until finally by papal decree regular schools of medicine were inaugurated, and medical art began its enlightened career. In the fifth century before Christ, Hippocrates elevated the practice of medicine to such an extent that surgical history is dated from his epoch. He was the contemporary of Socrates. Aside from his remarkable genius as physician and surgeon, the noble character of Hippocrates shines as an everlasting monument of professional worth. It was he who said of medicine, "It is of all the arts the most noble; but owing to the ignorance of those who practice it, and of those who, inconsiderately, form a judgment of them, it is at present far below all the other arts. Their mistakes appear to me to arise from this, that in the cities there is no punishment connected with the practice of medicine except disgrace, and that does not hurt those who are familiar with it. Such persons are like the figures which are introduced in tragedies, for as they have the shape and dress and personal appearance of an actor, but are not actors, so also are physicians many in title but few in reality." Half of the remarkable works which he has given to medical science are devoted to surgery.

Fractures and dislocations were as carefully adjusted and reduced as at the present time; abscesses of the liver and kidney were operated on without reserve, and those operations which we consider capital were very commonly performed; nor was the brilliancy of his fame acquired by mere accident. We have undoubted proof that his knowledge of surgical anatomy was acquired only after faithful and painstaking dissection. His surgical skill included the knowledge of complete resections of bones at the joints, but amputations were rarely practised. It is interesting to note that the use of suppositories was not unknown to him.

In the third century before the Christian era, Alexandria became the great school of anatomy, surgery, and medicine. Herophilus and Erasistratus were as distinguished for their surgical skill as for their anatomical knowledge. Science was cultivated to the highest degree, and the dissection of the human body, which had been hitherto prohibited, was now permitted. Very many of the anatomical names now in use originated in the investigations of Herophilus. The name of Erasistratus has been handed down as that of a bold and skilful surgeon. One member of this school, Ammianus, invented an instrument by which he broke down stones in the bladder, thus anticipating by two thousand years Civiale's discovery of lithotritry. When the great Alexandrian library was destroyed by fire, much that was valuable in surgical literature perished in the conflagration.

Rome then became the headquarters of science in all its departments. The medical and surgical art languished under the edicts which were publicly directed for their destruction. The early Romans of all ranks held surgeons and physicians in abhorrence, and trusted for cures, even in cases of dislocation and fracture, to spells and incantations. The first regular surgeon who settled in Rome was Archagathus, two hundred and twenty years B.C. He was a student of the Alexandrian school, thus transplanting the germ of surgical knowledge in the west. At first his skill procured for him a high reputation and the title of "Healer of Wounds," but the old prejudices soon revived, and he was banished from the capital with the title of "Executioner."

About the year 96 B.C. Asclepiades, a native of Bithynia, settled in Rome and acquired great renown as a physician and surgeon. His writings, though no longer in existence, have been quoted by Celsus, Scribonius, Largus, Cælius Aurelianus, Galen, Oribasius, Aëtius, Pliny, and others. He is supposed to be the originator of laryngotomy, and evidently made a specialty of diseases of the throat. It was owing to his great influence and skill that the prejudice against medical men came to an end in Rome. He was the personal friend of Cicero, who refers to him when he says, "Nothing brings men nearer to the gods than the giving of health to their fellow-creatures." Cassius, a student of Asclepiades, was a distinguished anatomist and surgeon. At the

beginning of the Christian era the art of surgery had advanced to an honorable position in the Roman capital. Celsus, a distinguished and learned doctor, stood easily at the head of the profession. He improved the mode of performing lithotomy and amputation, described the operation for cataract, and is said to have been the first to recommend the application of ligatures to wounded arteries, for the purpose of arresting hemorrhage. His works possess such remarkable value that they have "always been admired by classical scholars for the purity and beauty of their Latinity, and highly valued by our own profession as one of the most precious monuments of antique surgery now extant." In examining his writings, we are struck by the minute attention to details, and the earnest practical instruction contained in them. That his works can survive through all these centuries and remain storehouses of professional instruction, is enough to illustrate the grandeur of his knowledge. Soranus was the first gynecologist of whom we have any special knowledge; he made use of the vaginal speculum and of the uterine sound, and published a valuable treatise, *De utero et pudendo muliebri*. This work gives evidence of great improvement and knowledge in obstetrics and gynecology. Aretæus, of Cappadocia, who practiced in Rome during the latter half of the first century, was the first to employ blisters, using cantharides as we still do for that purpose. Rufus, of Ephesus, a distinguished anatomist and surgeon, lived during the reign of Tiberius. He is supposed to have been the first to tie an artery which had become aneurismal in consequence of being wounded in venesection. His treatise, *De appellationibus partium corporis humani*, is still extant. Rufus also called attention to the recurrent nerve. Galen, who practiced in Rome in the latter part of the second century, mainly obtained his great reputation by his medical practice. He rendered distinguished services in surgery in his treatment of fractures and dislocations and of hemorrhage by ligation. He was skilled in the art of bandaging, and was an excellent diagnostician. Oribasius, a native of Pergamos, a pupil of Zeno, flourished in the fourth century. He was a conservative surgeon, but a man of great learning and practical common sense. Aëtius, in the sixth century, recommended scarification of the legs in dropsy, tried to dissolve urinary calculi by internal remedies, studied the diseases of the eye, and is the first writer who notices the guinea-worm. He wrote on aneurisms, hernia, and other surgical subjects, but more especially on gynecology. His articles on the use of the vaginal speculum, the uterine sound, sponge tents for the dilatation of the os uteri, the surgical treatment of cancer of the breast, on the causes of difficult labor, and on the use of pessaries, suppositories, injections, are scholarly and practical. Paulus Ægineta, in the seventh century, was the last of the Greek medical and surgical writers. He was distinguished as an obstetrician, he opened internal abscesses by caustics, improved the operation of lithotomy, described several varieties of aneurism, extirpated the breast, performed laryngotomy and tracheotomy, and was the originator of the operation of embryotomy. His sixth book is regarded as the best treatise on surgery previous to the revival of letters. He contributed medical literature on the various forms of intestinal hernia. His directions for operating in strangulated hernia are considered unrivalled at the time at which he wrote. When the destruction of the Alexandrian Library took place, some of the works which were saved were translated into the Syriac and Arabic languages, by which mediums it was dispersed throughout Western Asia, and so it came to pass that the seat of learning was transferred for a time from beneath the shadow of the cross to the empire of the crescent, and from the classic shores of Italy and Greece to the warlike followers of Mahomet and the fiery descendants of Ishmael."

The surgery of the Arabians is the surgery of the Greeks. In the seventh century the Caliph Al-Mansoor founded a college in Bagdad, which became a famous centre of intellectual culture. Bagdad contained thousands of students in the several departments of arts and sciences, and besides its schools and colleges possessed public hospitals and laboratories.

"Whether in the East or in the West, surgery may boast of having had an origin that well deserves to be called noble, for the earliest practice arose from the most generous sentiment which nature has implanted in the heart of man—namely, from that sympathetic benevolence which leads us to pity the misfortunes and sufferings of others, and inspires us with an anxious desire to alleviate them. He who first saw his fellow-creature suffer could not fail to participate in the pain and endeavor to find out the means of affording relief." Thus in every land, whether among Greeks or Romans, or among the followers of the cross or the crescent, the art of surgery became an absolute necessity, and the most brilliant and enlightened minds labored industriously for its improvement. In the early part of the tenth century there was born in Persia a celebrated Arabic writer, Rhazes by name. He had charge of an immense hospital at Bagdad, had been a traveller in foreign lands, and was well read in the medical literature of his time. His writings clearly prove him to have been a surgeon of high rank. He was the first to describe spina bifida. Avicenna, called the prince of physicians, was one of the most distinguished of the Arabic writers. The works of Hippocrates, Galen, and Avicenna are supposed to "have exercised a greater and more continued influence over the minds of medical men than any or all the authorities the world has ever produced." Haly Abbas was also born in Persia, and dwelt most of his time in Bagdad. His large hospital experience taught him the value of clinical instruction for medical students. His works on surgery were of very advanced and practical stand

ing, and exercised a long and powerful influence in mediæval times. Albucasis, who died in 1122, described an instrument for the cure of fistula lacrymalis, the removal of tumors by ligature when the knife is inexpedient, the suture of wounded intestines, which marks a tremendous advance in the era of surgery, the use of the probang in obstruction of the gullet, etc.; and is the only writer on surgery of ancient times who describes the instruments used in each operation. These he illustrated with figures or drawings; ninety-seven operations requiring the knife are thus described. He may be said to have made a specialty of the use of the cautery, actual and potential. This was a favorite practice with all the Arabian surgeons. Long before his time, Dioscorides, the contemporary of Celsus, spoke of the use of the actual cautery as the Arabian burnings. Not less than five-and-twenty editions of his works have been printed, from the earliest at Venice, in 1471, to the latest at Oxford, in 1778. About the year 1070 there was born in the city of Seville the celebrated Saracenic surgeon, Abenzohar. He performed the operation of bronchotomy, and, on account of his boldness in surgical procedure, was known as the "Experimenter." He was the first to describe methods of artificial alimentation, the first anticipating the œsophageal tube, the second the use of nutritive baths, and the third mode that of rectal alimentation. Oribasius also wrote concerning clysters. Averroës, the student of Abenzohar, regarded his "admirable master" with the greatest reverence, calling him "the Glorious," "the treasury of all medical knowledge," "the supreme of physicians from the days of Galen to his own times." The father and grandfather of Abenzohar were eminent physicians, and thus it would appear that he almost inherited his profession. His natural medical training thus probably accounts for his thorough and painstaking researches as an anatomist. We have not time to refer to the medical history of Sahrnum, or to make any reference to the *Susruta*, the ancient surgical treatise of the Hindoos.

During the dark ages medicine and surgery were usurped by the priesthood, who drove a thriving and lucrative business by combining the medical and ecclesiastical professions. Their ignorance was only equalled by their cupidity and venality. The healing art was degraded to the last degree. Pettigrew gives the names of nearly fifty Roman Catholic saints who were believed to have special control over certain individual diseases, both medical and surgical. Each well and spring had its protecting saint; and charms, relics, and amulets as preventives and cures of disease prostituted the healing art to priestcraft and quackery.

The episcopal college of Paris had medical professors who gave advice and treated surgical cases in the interiors of the churches. Pope Alexander III. denounced these priest-physicians, and finally medicine was effectually divorced from theology by a special bull which permitted physicians to marry. After the emancipation of the healing art from the hands of the clergy, Pitard, an eminent surgeon in Paris, founded in 1271 the College of Surgeons.

During the thirteenth century many of the schools of Bologna, Padua, Naples, Paris, Montpellier, Toulouse, Valencia, Tortosa, and Oxford were founded. To the labors of Gerard de Cremona, of Lombardy, we owe much of the incentive to medical study. He translated from the Arabic works and transmitted to the Latins the medical knowledge of the East. In the fourteenth century, surgery, which had been well-nigh extinct in England, received new life in the labors of Gilbertus Anglicus, John of Gaddesden, and John Arderne. In the middle of that century Guy de Chauliac was the first to describe the Cæsarian operation practiced at Avignon. During the fifteenth century the local application of arsenic for cancer was proposed by Taranta, a Portuguese surgeon practicing at Montpellier.

Colot, a distinguished surgeon high in favor with Louis XV., in the year 1461 undertook a series of experiments upon the dead body, in order to investigate the operation of lithotomy. Permission was granted him by the king to operate on a convict who had been condemned to death. "The death sentence having been commuted to lithotomy, Colot performed the operation successfully in the churchyard of Saint Severius, in the presence of the king, cured his patient, received a liberal pension, advanced the art of surgery, and rendered his own name immortal." The names of Pierre Franco, François Russet, James and John Douglass, William Cheselden, J. J. Rau, and Frère Jacques are all associated with the history of lithotomy. The surgery of the sixteenth century may be said to be represented by Ambrose Paré. This was a brilliant period in the history of anatomy and surgery.

Among the eminent anatomists were Andreas Vesalius, Columbus, Fallopius, Fabricius, Acquapendente, and others. To Paré is given the credit of introducing the ligature into surgery. "I think it was taught me by the special favor of the sacred deity," says Paré; "for I learnt it not by my masters, nor of any other, neither have I at any time found it used by any, only I have read it in Galen that there was no speedier remedy for staunching of blood than to bind the vessels through which it flowed toward their roots—to wit, the liver and the heart." The ancient surgeons had spoken of the ligation of blood vessels, but Paré certainly brought it into practical use. Thomas Gale, a military surgeon in England, was a contemporary of Paré, and received his education from Richard Ferris, sergeant-surgeon to Queen Elizabeth. Early in the seventeenth century, 1612, a Scotchman named Lowe published a discourse on the whole art of chirurgery; and about fifty years later Wiseman, who has been appropriately termed the Paré of England, and the true father of British surgery,

flourished. He was sergeant-surgeon to Charles II., and his surgical works published in 1676 may still be read with interest. He was the first to dispel the dangerous belief that gunshot wounds were of a poisonous nature, and had consequently to be treated with the most painful kinds of dressing. Ancient surgical works abound with instructions concerning the poisonous nature of gunshot wounds.

Dionis, the French surgeon, thus refers to the invention of gunpowder: "Some ages since there came out of Hell a Monster in the Habit of a Monk, who, trying chymical experiments, invented a Composition of salt-petre and sulphur which we call Gunpowder. This diabolical invention," etc. It was difficult to overcome the erroneous idea that these wounds were necessarily poisonous. In spite of the great learning of many of the surgeons of this epoch, prayers, incantations, and charms, with or without boiling hot oils, the actual cautery, and the vilest of irritating ointments, were the usual remedies employed. Purmann, an army surgeon, thus describes the formula for weapon salve: "Earthworms, human mummy, swine's brain, magnet, and the moss of a man's skull that was either killed or hanged, and gathered when the star Venus is predominant." This ointment he had always with him in the camp, and often used it with great success. The peculiar method of using the ointment is, that the weapon wherewith the patient was wounded is anointed and not the wound itself.

Lawrence Heister, also an army surgeon, obtained great eminence in his treatment of gunshot wounds. James Young, an English surgeon, was the first to perform the flap operation in amputation. Schulteheis, a German surgeon of distinction, flourished about this time. Rau, of Leyden, one of the most successful lithotomists of any age, was the pupil of Frère Jacques.

Roonhuysen was the first to divide the sterno-mastoid muscle for wry neck, and may thus be regarded as the inventor of tenotomy. In 1728 was born John Hunter, the most distinguished anatomist and pathologist of the eighteenth century. His treatise on the blood, inflammation, and gunshot wounds is one of the most remarkable books published in the English language. The Peninsular War afforded him a vast field for valuable experience. He founded the famous Hunterian Museum of 14,000 specimens, and at a cost of £70,000 sterling. His remains rest in Westminster Abbey. The first surgical journal of which we have any record was that published by Desault, who was born in 1744. He invented the straight amputating knife. While attending Louis XVII. he died suddenly, and, as has been supposed, by poisoning. His successors, Chopart and likewise Doublet, who also attended the Dauphin, both followed him to the grave within four days. Monro, Benjamin Bell, and John Bell were celebrated surgeons of this century. Petit was celebrated for his work on diseases of the bones, and Desault was distinguished for his improvements in surgical instruments.

Richter and the illustrious Haller were distinguished surgeons of Germany.

Lancisi, Morgagni, and Scarpa were men of great renown in Italy, and had an international reputation as distinguished surgeons.

The London medical schools can point with pride to the names of Abernethy, Blizard, Brodie, Astley Cooper, Dalrymple, Earle, Guthrie and Hennen, Aston Key, Liston, Stanley, Travers, Tyrrell, Ware, James Wilson, and many other nearly equally celebrated surgeons of an earlier date. More recently we have the names of Arnott, Bowman, Erichsen, Fergusson, Prescott Hewitt, Hilton, Lane, Lawrence, Luke, Paget, Spencer Wells, and a host of others. In Edinburgh were Sir Charles Bell, Lizars, Miller, Syme (whose name will ever be associated with a special amputation of the foot and with the operation for stricture), and Sir James Simpson, the distinguished gynaecologist and the discoverer of the application of chloroform in surgical practice. Among the most recent advances may be mentioned the practice of antiseptic surgery, with which the name of Sir Joseph Lister (q. v.) is so worthily associated. The results following the Listerian practice have revolutionized surgery; recoveries from many serious operations have taken place in remarkably short periods, and with an absence of suppuration, and other secondary effects of the inflammatory process. See ANTISEPTICS.

Among the surgical celebrities of Dublin must be mentioned Peile, the inventor of the lithotome and staff; Todd, the father of the late eminent Dr. Todd, of London, who was the first to successfully revise the treatment of aneurism by compression; Colles, the first to describe the fracture known as Colles' fracture of the radius; Carmichael, distinguished for his opposition to the indiscriminate use of mercury; Bellingham and Hutton, Cusack, Porter, McDowel, and Sir Philip Crampton; Adams, well known for his treatise on the diseases of the joints and chronic rheumatism; R. W. Smith, celebrated for his researches on fractures and neuroma; and Jacob, the discoverer of the *membrana Jacobi*. It would be impossible to mention a tithe of the names of those who have attained high surgical celebrity during the present century.

The Barons Dupuytren and Larry, Amussat, Chassaignac, Civiale, Brasdor, Broca, Desmarre, Nelaton, Verneuil, Richet, Labbé, and Belpéau have honorably sustained the reputation of French surgery. Beer, the oculist; Chelius, Dieffenbach, Von Grafe, Gurlt, and Jäger, the oculist; Langenbeck, Stromeyer, Wützer, Billoth, Braun, Dümreicher, Nüsbaum, Bergmann-Bruns, and Tiersch constitute but a small portion of the eminent surgeons of Germany. Callisen, of Copenhagen, Porta, of Pavia, and Perogoff, of St. Petersburg, may be taken as the surgical representatives of their respective countries. In gynaecology the names of Späth, Scanzoin, De Paul, Hecker, Heger, Gaillard, Martin, Winckel, Rokitsky, Priestley, Lawson Tait, Johnson, Thornton,

Orthmann, Mugebauer, Folkmann, Kaltenbach, and last but not least, Schroeder, Barnes, and Leischman, distinguished obstetricians.

In our own country the history of surgery would readily fill a volume by itself. The annals of American medical science are simply unsurpassed. From the humble beginnings before the Revolutionary War, American medical science has advanced to the very highest position of professional worth and dignity. From Benjamin Rush down through the century of honor in medical progress the names of Americans are recognized throughout the world. Mott, Van Buren, Parker, Post, Nathan Smith, Sands, Warren, Bigelow, Gross, Pancoast, Morton, Agnew, Hamilton, Wood, Sayer, Janeway, Richardson, and Weir are among the most distinguished of our American surgeons. While in the field of gynecology the brilliant achievements of Sims, Thomas, Emmet, Peaslee, Skene, Crosby, Storer, Jackson, Parvin, and Cushing are recognized wherever medical science is known. For works of reference on surgical subjects we have in recent times the admirable treatises of Holmes, Hamilton, Smith, Ashurst, Gross, Bryant, and many others.

SURICATE, the *Ryzana capensis*, a carnivorous animal of s. Africa and the cape of Good Hope, sometimes called *zenick*. It belongs to the family *viverridæ* (q.v.), and is, therefore, allied to the civet (q.v.), genet (q.v.), ichneumon (q.v.), and paradoxurus. The generic characteristics are: feet rather long, and toes with robust claws adapted to burrowing habits; tongue furnished with horny *papillæ*; ears small; tail long, slender, and pointed. The *R. capensis* is about four feet long, including the tail; fur, a mixture of brown, white, yellowish, and black. The color of the hair is brown at the bottom, black near the tips, and hoary at the points; those on the back undulated, inside of the legs, yellowish-brown; tail, tufted with black. According to Pennant it is called the *meer-rat* at the Cape. It also resembles the ichneumons in habits, and its urine is very fetid. It eats flesh, preys on mice, and devours quantities of cockroaches. Sometimes it is domesticated for the purpose of exterminating vermin.

SURINAM. See GUIANA, DUTCH.

SURINAM BARK. See ANDIRA.

SURMOUNTED, in heraldry, a term used to indicate that one charge is to be placed over another of different color or metal, which may respectively be blazoned: Sable, a pile argent surmounted by a chevron gules; and, argent, a cross gules, surmounted by another or.

SURMULLET, *Mullus*, a genus of acanthopterous fishes of the family *mullidæ*, a small family formerly included in *percidæ*, but distinguished by having two dorsal fins widely separated from one another, the first spinous; and large, easily detached, strongly ciliated scales on the head and body. The genus *mullus* has no teeth on the upper jaw, but a disk of pavement-like teeth on the front of the vomer. Two long barbels hang from the under jaw, or, when not in use, are folded up against it. Only two species are known, both abundant in the Mediterranean, and both found on the British coasts. They very generally receive the name MULLET, by which they are confounded with a very different genus. The STRIPED SURMULLET, or STRIPED RED MULLET (*M. surmuletus*), is sometimes very plentiful on the southern coast of England, but is rarer toward the north. It approaches the shores in summer, and many surmulletts are then taken in mackerel nets; but at other seasons it is only obtained from comparatively deep water by trawl-nets. It sometimes attains, in the Mediterranean, a weight of six or seven pounds, but has never been known much to exceed three pounds in the British seas, and is seldom more than two pounds in weight. The ancient Romans, who held it in the highest esteem, gave prodigious prices for fish of unusually large size. They kept surmulletts in their *vivaria*; but there the fish did not increase in size. The color is pale pink, with three or four yellow longitudinal stripes; but where any of the scales have been rubbed off, beautiful tints of purple and bright red appear, which takes place also during the struggles of the fish when dying, and the Romans were therefore accustomed to bring surmulletts alive into their banquetting-rooms, that the guests might see them die, and enjoy the brilliant display of color, before eating the fish. The liver was regarded as peculiarly delicious, and was bruised in wine to make a *garum* for the flesh. The surmullet is still regarded as one of the best of fishes.—The RED SURMULLET, or PLAIN RED MULLET (*M. barbatus*), is very rare on the coasts of Britain. It is a much smaller fish than that already described. Other species of *mullidæ* are found in tropical seas.

SURNAME (either from its being an additional name—Fr. *surnom*, Ital. *sopranome*—or from the practice of writing it over the Christian name, which is to be seen in the court rolls and other ancient muniments), in modern Europe, the family name. The Roman *cognomen* partook somewhat of the same character; but the introduction of the surnames of modern time cannot be traced further back than the latter part of the 10th century. See NAME.

SURPLICE (Lat. *super pellicium*, above the robe of fur), a linen or muslin vestment, worn by clerks of all degrees of orders in the discharge of their public religious offices. It is by some supposed to be derived from the longer and more flowing vestment which, in the Roman Catholic church, is still used in the mass, and is called the "alb," but in that church the surplice is worn not alone by priests, but by all who have been admitted even to the church tonsure. Its most ordinary use is for the service of the choir, and it is also employed, along with the stole, by priests in the administration of the sacraments, and in preaching. The use of the surplice was strongly objected to by the Calvinistic

and Zwinglian reformers on the continent, and by the Puritans in England, who regarded this vestment as a relic of popery, and made it the subject of vehement denunciations. The argument against it is to be found in Beza, *Tractat. Theolog.*, iii. 29, and its defense in Hooker's *Ecclesiastical Polity*, book v., ch. 29. Ere ritualism became so common in England, no little stir used from time to time to be created by the use of the surplice by the preacher in the pulpit, contrary to the more general practice in the Anglican church. Preaching in the surplice has been associated in the popular mind with a Romanizing tendency, although it is difficult to say on what basis this association rests.

SURREY (Sax. *Suth-ric*, the s. kingdom), an inland co. in the s. of England, bounded on the n. by Middlesex, and on the e. by Kent. Area, 483,178 acres; pop. '91, 1,730,871. The middle of the county is traversed from w. to e. by a well-marked ridge of the North Downs, which rises in Botley Hill, above Titsey, to the height of 880 feet. On the n. side of this range, the land slopes gradually to the banks of the Thames, which runs along the northern border; but on the s. side, the descent is rugged and broken, affording pleasing and sometimes romantic scenery. Surrey of the main range, and about four miles south of Dorking, is Leith Hill, 993 ft. high, the most important elevation in this quarter of the country. Stretching along the southern bank of the Thames, and extending over a space about 6 m. in breadth, is a tract which belongs to the London clay formation; further south, and likewise extending from w. to e., there is a tract of plastic clay, varying in breadth from one to five miles. Chalk, weald clay, and iron sand formations occupy the s. of the county. The principal streams are the Mole and Wey, tributaries of the Thames. The soil of the northern half of the county is fertile; in the w. and s.w. the land is, to a great extent, covered with heath. The climate is soft and mild in low-lying districts, and is favorable to the production of corn and grass. More than four-fifths of the entire area are under culture. In the n., in the vicinity of London, there are numerous market-gardens, the produce of which is sent to supply the markets of the metropolis. Hops, wheat, and the ordinary crops are raised. The county contains much wood, and the beauty of the scenery, and the facility of communication with London, have attracted many residents to Surrey, which is consequently studded over with mansions and villas. Manufactures are carried on in Southwark and in the other southern suburbs of London, as well as in Croydon, Guildford, Kingston, and Reigate, which are the principal towns. The county returns four members to the house of commons.

SURREY, HENRY HOWARD, Earl of, 1516-47; b. England; son of the third duke of Norfolk. His youth was spent in France, and at the court of Henry VIII. In 1540 and for some years later, he served in France and gained the title of field marshal; he captured Boulogne, was made its governor, and gained other victories, but was recalled to England after some slight reverses at St. Etienne. His influence at court was no longer as powerful as in the life of the duke of Richmond, Henry's natural son; charges of treasonable ambition were constantly urged against the duke of Norfolk and Surrey by the Hertford faction; and in 1546 the two were arrested; Norfolk was sent to the Tower, and Surrey was beheaded, 1547. As a poet he was the first to introduce the sonnet and blank verse in English poetry. He wrote many sonnets, amatory verses, and elegies, and an elegant translation of parts of the *Æneid*.

SURROGATE, an officer having jurisdiction over the personal property of decedents, and often a special jurisdiction over their real estate. The surrogate in England was a representative of the bishop in the diocesan courts, which down to 1857 exercised jurisdiction over the probate of wills, and the issue of letters testamentary and of administration, as well as in matters ecclesiastical. As the bishop could not always hold his court in person, he appointed a "substitute," *surrogatus*, to represent him. Such substitutes, originally ecclesiastics, but in later times lawyers, acted as judges in probate matters; and the court of the Archbishop of Canterbury held by his surrogate was the principal court in probate, admiralty, and marriage matters. A separate court of probate and divorce was established in 1857. In New Jersey the surrogate is only an inferior officer of the probate court. In New York there is a surrogate's court in each county held by the county judge, unless the county has more than 40,000 inhabitants, in which case a surrogate is elected for 6 years. See **PROBATE COURT**.

SURTURBRAND, a kind of brown coal (q.v.) found in the north of Iceland, and there used for fuel. It has a great resemblance to the black oak found in bogs. It is capable of being made into tables and other articles of furniture, but is too brittle to be cut into shavings by a plane.

SURRY, a co. in n.w. North Carolina, drained by the Yadkin and the Ararat rivers; traversed in the n.w. by the Blue Ridge; area, 490 sq.m.; pop. '90, 19,281, incl. colored. The surface is hilly and heavily wooded. The soil is fertile in some portions. The principal productions are corn, tobacco, wheat, and live stock. Co. seat, Dobson.

SURRY, a co. in s.e. Virginia, drained by the James river, which bounds it on the n.e., and by the Blackwater river; area, 298 sq.m.; pop. '90, 8256, incl. colored. The surface is irregular and heavily wooded. The soil is sandy. The principal productions are corn, peas, and pork. Co. seat, Surry.

SURVEYING. Land-surveying may be considered the earliest practical application of the art of geometry or earth measurement, and must have been in some more or less

rude form coeval with agriculture and the division or appropriation of the soil. In Rome, surveying was considered one of the liberal arts, and the measurement of lands was intrusted to public officers who enjoyed certain privileges; and it is probable that the system of measurement practiced by them was very similar to our plane surveying with the chain and cross-staff of the present day, and has been handed down to us through the feudal period. An examination of ancient records and title-deeds will show that both areas and boundary-lines of the different inclosures forming fields, hundreds, town-lands, etc., are often laid down with a considerable degree of accuracy.

Land-surveying may be considered under the following heads: (a.) Plane surveying with the chain, and without the aid of angular instruments, except the cross-staff or fixed angle of 90°. (b.) Modern engineering surveying, in which angular instruments are used. (c.) Coast and military surveying. (d.) Trigonometrical surveying (q.v.).

The fundamental rule of every description of land-surveying, from the humble attempt of the village school-master to lay down an irregular garden-plot, to the trigonometrical survey of a large extent of the earth's surface, when the aid of the most refined improvements of modern science is indispensable, is simply to determine three elements of a triangle, and thence to calculate its area.

In plane surveying with the chain, the three sides of a triangle, ABC, are supposed to be accessible, and are carefully measured on the ground, and then laid down or platted to scale on paper, when an accurate figure of the triangle will be obtained, on which the length of the sides can be marked. To get the area, however, it will be necessary to determine the length of the perpendicular line AD, and this is usually done (when possible) on the ground by means of a simple instrument called a cross, which consists of two sights or fine grooves at right angles to each other, and being placed on the line BC (keeping B and C visible in one of the sights), nearly opposite the angle A, is moved gradually till the angle A is intersected by the other sight. The line AD can be also laid down on the drawing, and its length found by scale, and afterward verified on the ground, or it may be at once laid down on the ground by the use of the chain alone. An improved reflecting instrument, called an optical square, is also often used for this purpose. Any boundaries along the lines or sides of the triangle, ABC, can be determined by the use of offsets (q.v.) or insets, as they occur on right and left of line. No matter what the form of the surface to be surveyed may be—polygon, trapezium, or trapezoid—it may thus be determined by a judicious subdivision into triangles; and when the survey is not of a very extended nature or character, and when no serious obstructions exist, chain surveying is both accurate and expeditious, especially if proof or tie-lines are properly introduced, for the purpose of testing the accuracy of the work.

In every description of surveying, it is best to make the original triangle as large as possible, and to work from a whole downward, rather than build up a large triangle by the addition of several small ones. It would be impossible here to lay down rules to meet the many difficulties which arise in the practice of surveying, and indeed the best test of a good surveyor is the ease with which he will overcome local obstructions, which appear almost insurmountable to a novice, or even to a theoretical surveyor with little field practice.

Where buildings or other impediments are found in the measurement of a straight line, they are generally passed by the erection of short perpendiculars sufficient to clear the obstacles, and a line parallel to the original measured as far as they exist, when the original line can be again resumed. Differences of level, occurring in measuring a line where no instruments are used, are generally compensated or allowed for by the judgment of the surveyor.

In registering the dimensions taken on the ground, such as sides of triangles, offsets, intersections of roads, fences, etc., and everything necessary to make a perfect delineation or plan of the surface, surveyors use what is called a field-book, the mode of keeping which varies very much with individual practice. Some surveyors use hand sketches or rough outlines of the form of the ground, and mark the dimensions on them, while others use the ordinary form of field-book, or a combination of the two methods, which perhaps is the best when any difficult complications happen on the ground, such as the frequent occurrence of buildings, enclosures, water, etc., along the line. In the ordinary field-book, the center column, commencing from the bottom, represents the length of any line or side of a triangle; and the figures in the column, the distance at which the offsets to the right or left are taken, or where roads, streams, fences, etc., cross the line, or buildings adjoin the same. We give below the field-book of the assumed survey of the triangle ABC, with the different offsets and insets on its sides, and where roads, fences, streams, etc., cross them, the detail of which can be obtained by subdividing the triangle into smaller internal ones. The figure can thus be laid down from the book, and its area calculated by the formula $\frac{AB \times CD}{2}$ and the offsets and insets calculated, added, or deducted, by the methods given in OFFSETS.

Ponds, plantations, and enclosures of different kinds may be surveyed with a chain,

the longitude. Cable determinations of the longitude of Cambridge, from Greenwich, gave in

| 1872 " " | French cables to St. Pierre | " " 30.96 " |

From the system of large triangles is formed a system of smaller ones, that take in the details of the country. The maps are made on a scale from $\frac{1}{50000}$ to $\frac{1}{200000}$. A chain of triangles is generally run in the direction of the meridian, and other chains run perpendicular to it. By measuring the length of a degree near the equator, and one near the pole, the ellipticity of the earth can be calculated. In 1740 the French measured an arc of a meridian in Peru, and also one in Lapland, and the results have ever since been important in all investigations upon the figure of the earth. In the progress of all the national surveys, portions of the meridional arc have been measured. The coast survey has measured one from Nantucket to Farmington, Me., another from the Ocracoke inlet, N.C., to the head of Chesapeake bay. F. R. Hasslet, the first superintendent of the coast survey, began work in 1817. A system of primary triangles is now being carried across the continent, to combine the surveys of the Atlantic and Pacific coasts. The ordnance survey of Great Britain was begun in 1791. The extreme accuracy required in the field operations makes the progress slow; sometimes a whole season is needed for the observations at one station. Piccard, in 1669, made the first accurate measurement of a meridional arc, and the results obtained were used by Newton in demonstrating the law of gravity.

SŪRYA, in Hindu mythology, the god of the sun. His wife is, in later mythology, *Sārya*, who, in order to escape his embraces, transformed herself into a mare, but nevertheless became the mother by him of the twins *Aswins*, afterwards the heavenly physicians.

SURVILLE, MARGUERITE ÉLÉONORE CLOTILDE DE VALLON-CHALYS DE, 1405-80; is said to be the writer of poems first collected in 1803 by Vanderbourg. Some ascribe them to one of her descendants, the marquis Joseph Etienne de Surville, and others think these poems were written by the publisher Vanderbourg himself.

SUS, a district in Morocco, on the Atlantic ocean, between the Asaka river and the Atlas mountains; about 11,000 sq.m.; pop. about 750,000. The surface is mountainous.

SU'SA (Shushan in Daniel, Esther, etc., derived by some from shoshan, a lily), probably the modern Sus or Shush, in lat. 32° 10' n., and long. 48° 26' e., situated between the Chapses or Eulæus (Ulai in Daniel), and the Shapur, anciently the capital of Susiana (the *Elam* of Scripture, mod. *Khusistan*), and one of the most important cities of the old world. Its foundation is variously ascribed by ancient writers to Darius Hystaspes, or to Memnon, the son of Tithonus; and its name, together with its ground-plan, is traced on Assyrian monuments at the time of Assur Bani Pal, about 660 B.C. At the time of Daniel's vision "at Shushan in the palace," it was under Babylonian dominion, but came, at the time of Cyrus, under Persian rule; and the Achæmenian kings raised it to the dignity of a metropolis of the whole Persian empire, and as such Æschylus, Herodotus, Ctesias, Strabo, etc., speak of it. At the Macedonian conquest it was still at its height, and Alexander is reported to have found in it vast treasures, together with the regalia. On Babylon becoming the principal city of Alexander and his successors, Susa gradually declined, but seems still to have contained enormous wealth at the time of its conquest by Antigonus (315 B.C.). It was once more attacked by Molo in his rebellion against Antiochus the Great; and during the Arabian conquest of Persia it held out bravely for a long time, defended by Hormuzan. The ruins of its ancient buildings, the palace described in Esther among them, cover a space of about three miles. The principal existing remains consist of four spacious artificial platforms above 100 ft. high. Traces of a gigantic colonnade were laid bare by Loftus, with a frontage of 343 ft. and a depth of 244. Cuneiform inscriptions exist, together with many other relics similar to those found at Persepolis (see PERSEPOLIS; compare also CUNEIFORM). The "tomb of Daniel" shown near Susa is a modern Mohammedan building. Besides the valuable works of Loftus, important excavations have been made on the site by Churchill, Dieulafoy, and others. See Dieulafoy, *L'Acropole de Suse* (1890) and Billerbeck, *Susa* (1893).

SU'SA (anc. *Segusio*), a city of northern Italy, province of Turin, stands on the right bank of the Dora Riparia, at the foot of the Cottian Alps, 32 m. w. of Turin. It is an episcopal see, and has a cathedral consecrated in 1028. Among its other notable buildings are the episcopal palace, the town hall, and the Borgo de' Nobili. The surrounding country produces wines, fruits, mulberry-trees, and wood. The road over Mont Cenis, opened in 1810, begins at Susa. Pop. '81, 3303.

Susa, called by the Romans *Segusio*, is a very ancient city; it was founded by the Celts, and was, in the reign of Augustus, the capital of the Celtic chief Cottius, from whom the Cottian Alps received their name, and during the empire was the starting point for crossing Mont Cenis. A triumphal arch, erected by Cottius A.D. 8, in honor of Augustus, still remains.

SUSA, a port of Tunis on the gulf of Hammamet in the Mediterranean sea. It is surrounded by old walls, and in the neighborhood are large plantations of olives and vines. It is the seat of a court and carries on considerable trade in olive oil, grain, wool, etc. A railway line connects it with the cities of Tunis and Cairoan. The roadstead is bad, and the depth along the quays is only about 4 feet. Susa is the site of the Roman city of Hadrumetum. Pop. about 18,000, including the garrison and some 4000 Europeans and 1000 Jews.

SUSANNAH, HISTORY OF, *The Judgment of Daniel*, also *Susannah and the Elders*, are the different titles of a well-known story, which forms one of three apocryphal additions to the book of Daniel; the others being *The Song of the Three Holy Children* and *The History of Bel and the Dragon* (see **BEL AND THE DRAGON**). Susannah, the wife of Joiachim, and daughter of Hilkiiah, celebrated alike for her beauty and her virtue, was falsely accused of adultery by certain "lovers," whose advances she had spurned; and how, being condemned to death on their evidence, she was saved by the wise Daniel, who tore the mask from her enemies, and caused them to experience the fate they had designed for her. The question—not a very important one certainly—has been much debated, both in the early and later times of the church, whether or not the story of Susannah is true; and arguments (of various weight) have been adduced to show that the book is a fabrication, a fable, a legend, and a history. The most probable view, perhaps, is that which regards it as a tradition of something that did happen in the life of Daniel, but which has been molded into a moral fiction by the hand of a literary artist. The original is believed to have been Greek and not Hebrew. In most MSS. it precedes the first chapter of the book of Daniel, and so we find it in the old Latin and Arabic versions; but the LXX., the Vulgate, the Complutensian Polyglot, and the Hexaplar Syriac place it at the end of the present book, and reckon it as the 13th chapter.

SUSPENSION, in music. A note is said to be suspended when it is continued from one chord to another to which it does not properly belong, and to a proper interval of which it must eventually give way.

SUSPENSION BRIDGE, a former town and port of entry in Niagara co., N. Y.; on the Niagara river; 13 miles s. of lake Ontario, and about 20 miles n. of Buffalo. In 1892 the town and the village of Niagara Falls were consolidated and incorporated as the city of Niagara Falls (q. v.).

SUSPENSION BRIDGES. In these bridges the roadway is suspended from cables passing over piers or towers, and firmly fixed at their extremities. When the roadway is equally loaded over its length, the curve of the cable is approximately a parabola. The weight of the roadway being known, the strain upon the cable, and its requisite strength, are readily determined. For example, in fig. 1, if A be the center of the bridge, and it be required to find the strain upon the cable at the point B, it is evident that the weight of the roadway between A and B is supported by the cable at B; we have then to find what strain in the direction of the length of the cable will support this vertical load. By the principles of mechanics, if we draw a right-angled triangle BCD, of which the side BC is a tangent to the curve at B, CD is vertical, and BD horizontal; and if the length of CD represent numerically the load on AB, then BC will represent numerically the strain on the cable produced by that load, and BD will be what is called the horizontal component of this strain. This horizontal part of the strain is the same for every part of the curve; it is the total strain on the cable at the center A, and the strain carried over the towers and balanced by the backstays, which are firmly anchored to the ground behind them. In this manner the conditions of strength and stability of a bridge uniformly loaded are easily determined, but when we have a rolling load which is heavy in proportion to the weight of the bridge, as, for example, a railway train, the case is very different, for when the train only occupies one half of the bridge, the cable will be depressed toward that side, and raised at the center; thus an undulation will be produced in the bridge, which, if the train be moving rapidly, would endanger its stability. Various combinations have been devised to overcome this difficulty. The most simple, and practically the best, is to stiffen the roadway so that the strain of the passing load is distributed over a considerable length of the cable. In this manner large railway bridges have been constructed in America; among them is that over the Niagara above the falls, with three lines of rails on it, of which the span is 822 ft., and the height of the platform above the river, 250 feet; it is supported by four wire cables, each containing 3640 wires. Trains pass over it at the rate of 10 m. per hour. An ordinary suspension bridge is liable to both vertical and horizontal oscillations, the former taking place when a train or other load is passing over it, and the latter being due to the action of the wind. These oscillations cannot be altogether prevented, but can be so reduced as to be harmless by the use of stays, stretching both from the towers and from points on shore to various parts of the bridge. Suspension bridges are generally used in positions where the span is great, and the rolling loads neither great in proportion to the weight of the bridge itself, nor very rapid in their motion. Many beautiful examples are to be seen in Great Britain; among others, we may instance the Menai bridge, 580 ft. span, and the Clifton bridge, near Bristol, 703 ft. span. For other suspension bridges see **BRIDGE** and **RAILWAY**.

FIG. 1.

SUSPENSION OF ARMS. See TRUCE.

SUSQUEHANNA, an American river, rises as the North Branch in Otsego lake, in Otsego county, New York, and, flowing south-westward, receives the rivers Unadilla and Chenango, then, turning south, enters Pennsylvania, where it receives the Chemung, Lackawanna, West Branch, and the Juniata, and empties itself into the Chesapeake bay, at Havre de Grace, Md., 400 m. from its source, and 153 from its junction with the West Branch. It is a shallow, rapid, mountain river, with varied and romantic scenery. A canal was built along the main stream and branches, but the railroads have absorbed most of its former traffic. The river near its mouth is famous for water-fowl, especially the canvas-back duck, and has important fisheries.

SUSQUEHANNA, a co. in n. e. Pennsylvania, adjoining New York; drained by the Susquehanna river and several creeks; traversed by the Delaware, Lackawanna and Western, and the Erie railroads; area, 850 sq. m.; pop. '90, 40,093, chiefly of American birth, with colored. The surface is uneven, but not rugged. There are fine dairy and stock-breeding farms; oats, corn, wheat, potatoes, butter, and cattle are staples. Co. seat, Montrose.

SUSRUTA is one of the great medical authorities of ancient India. See *Medicine*, under SANSKRIT LITERATURE. His work is called *Ayurveda*, and consists of six books. It was edited by S'ri Madhusūdana Gupta, in two vols. (Calcutta, 1835-36.)

SUSSEX, a co. in s. Delaware, adjoining Maryland, bounded on the e. by the Atlantic ocean and the Delaware river; drained by Indian and Nanticoke rivers, and Mispillion creek; traversed by branches of the Philadelphia, Wilmington, and Baltimore railroad; area, 900 sq. m.; pop. '90, 38,647, includ. colored. The surface is level and heavily wooded. The soil is generally fertile. The principal productions are corn, wheat, and cattle. Co. seat, Georgetown.

SUSSEX, the n.w. co. of New Jersey, bordering on New York, separated from Pennsylvania on the w. by the Delaware river; 525 sq. m.; pop. '90, 22,259. The surface is hilly and the soil very fertile. This county produces the largest amount of butter of any in the state. It contains large deposits of iron, zinc, slate, limestone, and franklinite — a rare mineral. Co. seat, Newton.

SUSSEX, a co. in s. e. Virginia, drained by Stony creek, Nottaway and Blackwater rivers; 420 sq. m.; pop. '90, 11,100, chiefly of American birth, includ. colored. It is intersected by the Atlantic Coast Line and the Norfolk and Western railroads. Its surface is hilly and largely covered with forests, which supply the lumber, which is the principal source of revenue. The soil is fertile, producing grain, tobacco, and dairy products. Co. seat, Sussex.

SUSSEX (South-Saxons), a maritime co. in the s. of England, bounded on the n. by Surrey and Kent, on the s. by the English channel, and on the w. by Hampshire. Area, 936,911 acres; pop. '91, 550,442. The South Downs (see Downs) traverse the county from w. to e., ending about 20 m. e. of Brighton, in the lofty cliff of Beachy head. The northern escarpment of the Downs is precipitous, but leads down to the fertile and richly wooded district of the Weald (see Downs). A remarkably productive tract, from 2 to 7 m. in breadth, extends w. from Brighton along the coast to the Hampshire border; and in the s. e. of the county the rich marsh lands that line the coast, and which are 30,000 acres in extent, make excellent pasture-grounds. Of the Down-land there are about 50,000 acres, covered with a fine, short, and delicate turf, on which the well-known breed of Southdown sheep are pastured. The principal industries of the county are agriculture and cattle-raising. The manufactures are unimportant. Sussex was at one time the center of English iron manufacture, the ironstone from which iron was extracted being found throughout the inland districts; but the last forge was extinguished, at Ashburnham, in 1809. Recently thick beds of gypsum have been found by boring and are now being worked at Netherfield. The chief rivers are the Arun, Adur, and Ouse, which have their origin in the n. of the county, and flow s. into the channel. In the s. of Sussex the climate is mild, and several large towns (see BRIGHTON and HASTINGS) are largely resorted to by those who seek health or relaxation. Seaford and Pevensey bays are much frequented by vessels, and the e. portion of the coast is defended by martello towers. Sussex is divided into six parliamentary districts,—of Chichester, Eastbourne, E. Grinstead, Horsa-ham, Lewes and Rye, each returning one member. Capital, Chichester.

SUSTENTATION FUND, a fund provided in the Free Church of Scotland for the support of the ministers of the church. The idea of such a fund was probably derived by Dr. Chalmers from the system of the Wesleyan Methodists, and a scheme devised by him was made public before the disruption, so that arrangements had been made, and a small sum already collected, when that event took place. The scheme was afterward carried into operation throughout the whole of Scotland, and continues unmodified to the present time. The members of the church are called upon to contribute, according to their own will and ability, to a common fund; of which, after payment of expenses, payments to a fund for widows and orphans, pensions to retired ministers, etc., an equal division is made among the ministers of the church, with a few exceptions, chiefly in the

case of newly formed congregations. The amount of the fund has gradually increased from £68,704 in 1843-44, to £172,408 in 1879-80, when 796 out of 1097 ministers received an equal dividend of £160, the surplus being divided among the ministers (780) of those charges whose contributions amounted to a certain average sum per member. Congregations are permitted to supplement the stipends of their own ministers, and if able are expected to do so. The supplement in some congregations in towns much exceeds the dividend from the fund; but in many parts of the country, the whole, or almost the whole stipends of the ministers are derived from it. The question had been much discussed, whether an equal dividend ought to be made, or a proportion established between the liberality of a congregation and the amount paid to its minister. The subject of the sustentation fund is of interest, not only to the Free church of Scotland, but to all unendowed churches.

SUTHERLAND, a co. in the extreme n. of Scotland, is bounded on the e. by Caithness and the North sea, on the n. and w. by the Atlantic, and on the s. by Ross and Cromarty. Area, 1,207,188 acres; pop. '91, 21,896, or about 11 per sq. mile. The coast-line is 60 m. in extent; and the shores, rugged on the n. and w., where they are broken by the force of the Atlantic, are comparatively flat on the east. The southern and central regions of Sutherland are the most elevated; and rivers, mostly from the middle of the county, flow e. and s.e. to the North sea, and n., n.w., and w. to the Atlantic. The principal mountain peaks are Ben More in Assynt (3273 ft.), and Ben Clibrigg (3154 ft.), while numerous other summits attain a height of over 2000 feet. The chief rivers are the Oikel and the Shin — which, with other affluents, unite to form Dornoch firth — the Brora, Helmsdale Water, and Naver. Extensive moors, the haunt of herds of red deer, stretch across the county; and the rivers and lakes, the chief of which are Loch Shin (q. v.), Loch Naver, and Loch Laoghall, form numerous low-lying valleys or straths. In the interior and western districts the climate is cold, and the county is often deluged with continuous rains; but in the eastern districts the climate is mild, and the soil very fertile in all agricultural produce. Coal, granites of various colors, marble, limestone, etc., are found. In Nov., 1868, traces of gold were found in a burn in Sutherland. A number of "diggers" were attracted to the district, but the gold found, though of excellent quality, was hardly sufficient to repay their labor. The Highland railway passes through the county. Manufactures are inconsiderable. There are good salmon, herring, and white fishings. Sutherland is well supplied with churches. The schools are well attended, and Gaelic is rapidly giving way to English. Almost the whole of the county belongs to the duke of Sutherland. The late duke was eminent for the zeal with which he devoted himself to the improvement of Sutherland, spending large sums in the reclamation of land by steam-plows, the construction of railways, etc. The chief town is Dornach, with a population of (1891) 514. The county sends one member to Parliament.

Sutherland receives its name from the Northmen, who frequently descended upon and pillaged it prior to the 12th c., and called it the southern land, as being the limit on the s. of their settlements. The condition of the people of Sutherland before 1811, in which year the county began to be opened up by roads, was miserable. Their sustenance, dependent mostly upon their half-starved flocks, was very precarious, and would have failed them often had not charity administered relief. A former duke of Sutherland effected what are known as the "Sutherland clearances," by compelling such of his tenants as could not support themselves, owing to the unsuitability to agricultural purposes of the districts upon which they dwelt, either to remove to more fertile districts, where they received land at a merely nominal rent, or to emigrate at his expense to Canada.

SUTHERLAND, GEORGE GRANVILLE WILLIAM SUTHERLAND-LEVESON-GOWER, Duke of Sutherland; b. England, 1828; succeeded to the dukedom on the death of his father, the second duke of the name, 1861. His mother, Harriet Elizabeth Georgiana, 1806-68, daughter of the earl of Carlisle, was noted for her beauty and as the patroness of the English anti-slavery society, and of other movements of reform and benevolence. The present duke was a member of the house for ten years before his elevation to the peerage, has immense estates in Sutherlandshire, Staffordshire, Shropshire, and Ross-shire. In 1881 the duke of Sutherland made a visit to this country, mainly for the purpose of examining our railroad system.

SUTLEJ, SATLEJ, or SUTLUJ (Sansk. *Satadru*, Thibet. *Langtschan*), an important river in the n.w. of India, the eastmost of the five rivers of the Punjab, rises in southern Thibet, not far west from the sources of the Brahmaputra and south of those of the Indus. After passing through the lakes of Manasarowar and Rakas Tal it flows n.w. for 150 m., when turning to the s.w. and breaking through the Himalayan range, it enters British territory and receives the Spiti or Li, a larger stream than itself. The Spiti is 8592 ft. above sea-level, when it joins the Sutlej, and the scene of the confluence of the two rivers is sublime in the highest degree. After flowing in all about 850 miles, in the course of which it is joined by the Beas and the Chenab, it falls into the Indus in lat. about 29° north. Its upper course is supposed to be identical with the Hesudrus, and its lower course (in which it is called the Ghara) with the Hyphasis of the ancients.

SUTLER, is a vendor of provisions allowed by the quartermaster-general to follow an army in the field, for the purpose of supplying the soldiers with such luxuries as they can afford to purchase. Sutlers are under martial law, accompany the baggage on a march, and are narrowly watched, and severely punished if found guilty of any irregularities toward either the soldiers or inhabitants of the country. In the French army a soldier in each regiment is licensed to act as sutler, and is called *vivandier*. See also CANTEEN.

SŪTRA (from the Sanskrit *śiv*, to sew, literally, therefore, a thread or string) is, in Sanskrit literature, the technical name of aphoristic rules, and of works consisting of such rules. The importance of the term will be understood from the fact, that the *groundworks* of the whole ritual, grammatical, metrical, and philosophical literature of India are written in such aphorisms, which therefore constitute one of the peculiarities of Hindu authorship. The object of the Sūtras is extreme brevity; and, especially in the oldest works of this class, this brevity is carried to such an excess, that even the most experienced would find it extremely difficult, and sometimes impossible, to understand these aphorisms without the aid of commentaries, which, however, are fortunately never wanting, wherever a work is written in this style. Though there is no positive evidence as to the cause or causes which gave rise to this peculiarity of Hindu composition, the method of teaching in ancient India—an account of which is afforded in some of the oldest works—renders it highly probable that these Sūtras were intended as memorial sentences which the pupil had to learn by heart, in order better to retain the fuller oral explanation which his teacher appended to them. But it is likewise probable that this method of instruction itself originated in the scarcity or awkwardness of the writing material used, and in the necessity, therefore, of economizing this material as much as possible; for that writing was known and practiced at the remotest period of Hindu antiquity, is now placed beyond a doubt, though a startling theory was propounded, some years ago, to the effect that writing was unknown in India, even at the time of the great grammarian Pāṇini. The manner, however, in which, up to this day, the Hindus are in the habit of keeping the leaves of their books together, seems to throw some light on the name given to this aphoristic literature. The leaves—generally narrow, and even at the present time often being dried palm leaves, on which the words are either written with ink or scratched with a style—are piled up, and, according to the length of the leaves, pierced in one or two places, when, through the hole or holes, one or two long *strings* are passed to keep them together. The name of Sūtra was probably, therefore, applied to works, not because they represent a thread or string of rules, but on account of the manner in which these works were rendered fit for practical use; just as in German a volume is called *band*, from its being “bound.” That a habit deeply rooted outlives necessity, is probably also shown by these Sūtra works; for while the oldest works of this class may be called Sūtras by necessity, there are others which convey the suspicion that they merely imitated the Sūtra style after the necessity had passed away, more especially as they do not adhere to the original brevity of the oldest Sūtras; and the Sūtras of the Buddhists (see PĪṬAKA), conspicuous for their prolixity, could scarcely lay claim to the term, if compared with the Sūtra of the Brahmanical literature.

SŪTRO TUNNEL. See TUNNEL.

SUTTEE (an English corruption from the Sanskrit *sati*, a virtuous wife) means the practice which prevailed in India, of a wife burning herself on the funeral pile, either with the body of her husband, or separately, if he died at a distance.

The practice of suttee is based by the orthodox Hindus on the injunctions of their Sāstras, or sacred books, and there can be no doubt that various passages in their Purānas (q.v.) and codes of law countenance the belief which they entertain of its meritoriousness and efficacy. Thus, the *Brahma-Purāna* says: “No other way is known for a virtuous woman after the death of her husband; the separate cremation of her husband would be lost (to all religious intents). If her lord die in another country, let the faithful wife place his sandals on her breast, and, pure, enter the fire. The faithful widow is pronounced no suicide by the recited text of the *rigveda*.” Or the code of *Vyāsa*: “Learn the power of that widow who, learning that her husband has deceased, and been burned in another region, speedily casts herself into the fire,” etc. Or the code of *Angīras*: “That woman who, on the death of her husband, ascends the same burning pile with him, is exalted to heaven, as equal in virtue to Arundhati (the wife of Vasishtha). She who follows her husband (to another world) shall dwell in a region of joy for so many years as there are hairs on the human body, or 35 millions. As a serpent-catcher forcibly draws a snake from his hole, thus drawing her lord (from a region of torment), she enjoys delight together with him. The woman who follows her husband to the pile expiates the sins of three generations on the paternal and maternal side of that family to which she was given as a virgin. . . . No other effectual duty is known for virtuous women, at any time after the death of their lords, except casting themselves into the same fire. As long as a woman (in her successive transmigrations) shall decline burning herself, like a faithful wife, on the same fire with her deceased lord, so long shall she be not exempted from springing again to life in the body of some female ani-

mal. When their lords have departed at the fated time of attaining heaven, no other way but entering the same fire is known for women whose virtuous conduct and whose thoughts have been devoted to their husbands, and who fear the dangers of separation." See for other quotations, H. T. Colebrooke, *Digest of Hindu Law*, vol. ii. p. 451, ff. (Lond. 1801); and his "Essay on the Duties of a faithful Hindu Widow," reprinted from the *Asiatic Researches*, in his *Miscellaneous Essays*, vol. i. (Lond. 1837). But how-ever emphatically these and similar passages recommend a wife to burn herself together with her deceased husband, it should, in the first place, be observed, that *Manu*, who among legislators of ancient India, occupies the foremost rank, contains no words which enjoin, or even would seem to countenance, this cruel practice; and, secondly, that no injunction of any religious work is admitted by the orthodox Hindus as authoritative, unless it can show that it is taken from or based on, the revealed books, the Vedas (see *SKRUTI*). An attempt has of late years been made by rājā Rādhakānt Deb, to show that, in a text belonging to a particular school of the black Yajurveda (see *VEDA*), there is really a passage which would justify the practice of suttee; but in the controversy which ensued on this subject between him and the late Prof. H. H. Wilson, it clearly transpired that the text cited by the learned rājā is of anything but indubitable canonicity; moreover, that there is a verse in the *rigveda* which, if properly read, would enjoin a widow not to burn herself, but, after having attended the funeral ceremonies of her husband, to return to her home, and to fulfill her domestic duties; and it seems, at the same time, that merely from a misreading of a single word of this verse from the *rigveda*, that interpretation arose which ultimately led to a belief and an injunction so disastrous in their results. See H. H. Wilson, "On the supposed Vaidik Authority for the Burning of Hindu Widows, and on the Funeral Ceremonies of the Hindus," reprinted from the *Journal of the Royal Asiatic Society*, vol. xvi., in his works, vol. ii., edited by Dr. Rost (Lond. 1862). That an immense number of widows have fallen victims to this erroneous interpretation of the oldest Vedic text, is but too true. Some fifty years ago, however, the East India company took energetic measures to suppress a practice which it was perfectly justified in looking upon as revolting to all human feelings, and which it would have likewise been entitled to consider as contrary to the spirit of the Vedic religion. This practice may now be said to have been successfully stopped; for though, from habit and superstition, even nowadays cases of suttee occur, they are extremely rare, and all reports agree that the enlightened natives everywhere, except, perhaps, in certain native states, support the action of government to repress this evil of bygone times.

SUTTER, a co. in n. central California; drained by the Sacramento and Feather rivers; traversed by the Southern Pacific railroad; about 590 sq. m.; pop. '90, 5469, chiefly of American birth. The surface is mostly level prairie, without timber. The soil is fertile. Co. seat, Yuba City.

SUTTER, JOHN AUGUSTUS, 1803-80, b. Baden; an officer in the Swiss service, who emigrated to this country in 1834, and became a trader at Santa Fé. In 1838 he made his way to the Pacific coast, thence to the Sandwich islands, and thence to Alaska, on his voyage from which down the coast, he was wrecked in San Francisco bay in 1839. Obtaining a grant of Mexican land, he established in 1841 a settlement called New Helvetia, where the city of Sacramento now stands. He was governor of the n. district of California under the Mexicans, and alcalde and Indian agent after it passed to the United States. In Feb., 1848, while enlarging his saw-mill race, he discovered gold. The discovery, however, brought him disaster. Gold diggers pre-empted his lands, and besides an annual pension of \$3,000, he received nothing else. He settled in Pennsylvania in 1873.

SUTTON, a co. in w. Texas; 1620 sq. m.; pop. '90, 658. Co. seat, Sonora.

SUTTON, a tp. in Meigs co., Ohio, including Racine vill. Pop. '90, 3750.

SUTTON, Amos, 1798-1854, b. Kent, England; in 1824 became a missionary to India where nearly all his life was spent. He compiled various text books in the Oriya language, and translated the Bible and many tracts into the same tongue. He also published a hymn book and several religious books in English.

SUTURE (Lat. *sutura*, a seam) is a term employed both in anatomy and surgery. In anatomy, it is used to designate the modes of connection between the various bones of the cranium and face. A suture is said to be *serrated*, when it is formed by the union of two edges of bone with projections and indentations (like the edge of a saw) fitting into one another. The coronal, sagittal, and lambdoidal sutures (see *SKULL*) are of this kind. A suture is termed *squamous*, when it is formed by the overlapping of the beveled (or scale-like) edges of two contiguous bones. There are also the *harmonia* and *schindylesis* sutures, the former being the simple apposition of rough bony surfaces, and the latter being the reception of one bone into a fissure of another.

In surgery, the word suture is employed to designate various modes of sewing up wounds, so as to maintain the opposed surfaces in contact. As it may fall to the lot of any person, on an emergency, to have to sew up a wound, the following general rules, applicable to all forms of suture, should be attended to. In passing the needle, the edges of the wound should be held in contact with the fore-finger and thumb of the left hand; and the needle should penetrate the surface at about an angle of 50° (rather more

than half a right angle), and should, at least, pass through the whole thickness of the skin at each stitch. The distance from the edge of the wound at which each stitch should enter and leave the skin, must vary with the depth of the wound; but there should never be less than the eighth of an inch between the margin of the wound and the entrance or exit of the needle. Sutures should not include vessels, nerves, muscles, or tendons. The line of the thread should cross that of the wound at right angles. For incised wounds on the surface of the body, when the edges can only be transfixed from the cutaneous surface, or when the opposite margins can both be traversed by one plunge, a curved needle (such as a common packing-needle) is most convenient, whereas a strong straight needle is more convenient for the completely free margins of extensive wounds, such as are left after amputation. Various forms of needles are used by surgeons. In the *twisted suture*, as used in the operation for hare-lip, the wound is transfixed by pins, around which, beginning with the uppermost, a thread is twisted.

SUVOROF, ALEXANDER VASSILIVITSH, Count, Prince Italiiski, a Russian field-marshal, and the most famous of Russian generals, was descended from a family of Swedish origin, and was born in Finland, Nov. 13 (O. S.), 1729. His father, who was an officer of the Russian army, and rose, in after times, to the rank of general and senator, enrolled young Suvorof at the age of 13, in the Semenof regiment, where he remained till 1754, when he was promoted to the grade of lieutenant. Suvorof was present in the Russian army engaged in the seven years' war (q.v.), and for distinguished behavior at Kunersdorf, received the grade of colonel. By a constant succession of eminent services in the Polish civil war (1768), in the war against the Turks (1773-74), in suppressing internal disturbances, and in subduing the Tartars of the Kuban (1783), he continued to grow in reputation, and rose to the rank of general. In the Turkish war (1787-92) he was commander-in-chief, for the first time brought the bayonet prominently into use in the Russian army, and decided by it the bloody battle of Kinburn (1787), which would otherwise have been a total rout. At the siege of Otchakof (1788), where he narrowly escaped being made prisoner, the battle of Fokshany (Aug. 1, 1789), which he gained in conjunction with the Austrians, and the decisive victory of Rymnik (Sept. 22, 1789), his headlong bravery, and peculiar system of rapid and repeated attack by overwhelming numbers, secured him complete success. For this last victory, which saved the Austrians under Coburg from annihilation or capture, Suvorof was created, by the Emperor Joseph II., a count of the empire, and from his own sovereign received the title of Count *Suvorof-Rymnikskii*. His last great achievement, and the one which has given a predominant coloring to Suvorof's reputation in western Europe, was the capture of Ismail (q.v.). Suvorof's report of his success was couched in the following terms: "Glory to God and Your Excellency; the town is taken; I am in it." He was then appointed (1791) governor of the newly conquered provinces; was afterward sent (1794) to complete the annihilation of the Polish monarchy, which he effected by repeated victories over the Polish armies, the capture of Praga by storm, and the *repossession* of Warsaw (Nov. 19), where a horrible massacre of the inhabitants took place. The grade of field-marshal, and presents of rare value, rewarded these successes. Under Paul, he fell into disgrace (1798), from his impatience of the emperor's fantastic military regulations, and was deprived of his rank; but being restored through English influence, he commanded the Russian auxiliary army sent to co-operate with the Austrians in Italy. In April, 1799, he reached Verona; compelled Moreau to retire behind the Adda with immense loss, including more than 8,000 prisoners; entered Milan in triumph (April 29); again defeated the French under Macdonald, after a desperate three days' conflict, at the Trebbia (June 17-19), and a third time at Novi (Aug. 15), depriving them of the whole of northern Italy. His campaign in Switzerland, which promised to bring him face to face with Massena, then the best general in Europe, was rendered abortive by the tardiness of the Austrians, and the Russians, in spite of Suvorof's remonstrances, were soon after recalled. His escape from the Schackenthal, where he was hemmed in by the French, is considered by many to be the most brilliant and daring retreat ever executed. While on his return to St. Petersburg, where a brilliant reception was awaiting him, he fell dangerously ill in Lithuania, and though, on his recovery, he found himself a second time in disgrace, he continued his route, and arrived privately in the capital, where he died sixteen days afterward, May 17, 1800. His remains were honored with a magnificent funeral, and the Czar Alexander erected a statue to his memory on the Champ-de-Mars. This most extraordinary man had naturally a weak constitution, but rendered it almost invulnerable by exercise, strict temperance, and the regular use of cold baths. His mode of life was of Spartan simplicity, and though the oddity of many of his habits seemed only calculated to encourage ridicule, they, in combination with his paternal care of his men, gave him a powerful hold on the affections of an army at once so ignorant and so thoroughly national in sentiment as the Russian. Suvorof, was inflexible in his resolutions and promises, and of incorruptible fidelity. His skill as a general has often been doubted, on the strength of his favorite remark, that all military tactics could be expressed in three words, *stoupai i bi*, "forward and strike;" but his career shows him to have been possessed of all needful military knowledge—though he hated idle maneuvering—and to have excelled in promptitude and ingenuity of conception, and boldness and rapidity of execution.

SUWAN'NEE, a co. in n. Florida, drained by the Suwannee, which bounds it on the w. and s.w.; intersected by the Florida Central and Peninsular railroad; about 640 sq.m.; pop. '90, 10,524, chiefly of American birth, inclu. colored. The surface is mostly level. The soil is sandy. The principal productions are cotton, corn, and sugar. Co. seat, Live Oak.

SUZERAIN (Fr. from Lat. *supremus*), a feudal lord. According to the feudal system, as developed in northern Europe, every owner of allodial lands was compelled to acknowledge himself the vassal of a suzerain and do homage to him for his lands. The term was applied less to the king than to his vassals, who had sub-vassals holding of them. See **ALLodium**.

SVENIGOROD KA, a t. of Russia, in the government of Kiev, 150 m. s. from Kiev, on an affluent of the Southern Bug. Pop. '80, 11,375.

SWABIA, **SUABIA** (Ger. *Schwaben*), or **SUEVIA**, an ancient duchy, in the s.w. of Germany, so named from a horde of Suevi, who spread over it in the 5th c., and amalgamated with the Alemanni, its previous inhabitants. It existed as a great duchy of the Frank empire till the 8th c., when Alsace and Rætia were separated from it, and the remainder, retaining its name of Swabia, was thenceforth governed by *nuntii camere*, or royal delegates, one of whom having, in 915, usurped the title of duke of Alemannia, was condemned by the German diet and decapitated in 917. Swabia at this time was bounded on the w. and s. by the Rhine, on the e. by the Lech (which separated it from Bavaria) and Franconia, n. by the palatinate of the Rhine and Franconia, and contained about 13,000 English sq. miles. In 918, however, Swabia was acknowledged as a ducal fief of the empire; and, after changing hands several times, was (1080) bestowed upon count Frederick of Hohenstaufen (q.v.), the founder of the illustrious house of this name, also known as the house of Swabia. Under the rule of this prince and his successors, Swabia became the most rich, civilized, and powerful country of Germany, and the ducal court was the resort of the minnesingers (q.v.); but the wars of the Guelphs and Ghibellines, and the quarrel with the French respecting Naples, put an end to the dynasty in 1268. The ducal vassals in Swabia rendered themselves almost independent, and professed to acknowledge no lord but the emperor. During these dissensions arose the lordships of Würtemberg and Baden, with numerous lesser states, holding direct of the crown, and opposed to them the cities, which strove also for an equal independence, and at last, in reward of important service, obtained in 1347 great additional privileges. A number of them united to make common cause against the neighboring feudal lords in 1376 (known as the *First Swabian League*); an opposite league was formed between Würtemberg, Baden, and 17 towns, in 1405, called the league of Marbach; and both took part in the war of Swiss independence, the former in support of the Swiss, the latter of the Austrians. At last the towns, which had been rapidly increasing in wealth and power, decided at Ulm, in 1449, to form a standing army and a permanent military commission for the forcible preservation, if necessary, of peace and order; and the count of Würtemberg, the most powerful of the opposite party, having joined them, was appointed military chief of the league, which ultimately grew up into the *Great Swabian League*, and exercised both administrative and judicial authority over the whole country, effectively repressing feudal quarrels. In 1512 Swabia became one of the ten circles into which Germany was now divided, received its complete organization in 1563, and retained it almost without change till the dissolution of the empire in 1806. But during this period the wars of the towns with Würtemberg, the peasants' war, of which Swabia was one of the foci, the thirty years' war, and those between France and the empire, destroyed the democratic constitution of the towns, and with it their energy, and then their prosperity disappeared, leaving now no relic which could suggest their former great political importance.

SWAIN, a co. in w. North Carolina, adjoining Tennessee; drained by the Little Tennessee river; bounded on the n. by the Great Smoky mountains; area, 425 sq.m.; pop. '90, 6577, with colored. The surface is even and well wooded. The soil is only partly fertile. The principal productions are corn, tobacco, and pork. Co. seat, Bryson City.

SWAIN, CHARLES, 1803-74; b. Manchester, England; called the "Manchester poet;" for 14 years employed in the dyeing establishment of his uncle, afterward became an engraver. While connected with the mill he began to write for magazines and annuals. He published various poems and sketches, some of which were translated into German and French. *Dryburgh Abbey*, an elegy on Sir Walter Scott, was written in 1832; new ed. 1868. An edition of his poems, with a portrait, and an introduction by Charles Card Smith, appeared in 1857. Wordsworth, Southey, and James Montgomery were among his friends. In 1857 he received a civil-list pension of £50 per annum.

SWAINSON, WILLIAM, b. England, 1789; served in the British army 1807-15. He studied natural history; went to South America in 1815, and afterward settled in London. He was at one time attorney-general of Tasmania, whither he had emigrated in 1841. He began the publication of *Zoological Illustrations* in 1820, and *Exotic Conchology* in 1821. Among his many works are *Naturalist's Guide* (1822); a number of natural history volumes in Lardner's *Cabinet Cyclopædia*. He died in New Zealand in 1855.

SWALE. See YORKSHIRE.

SWALLOW, *Hirundo*, a Linnæan genus of birds of the order *insessores*, and tribe *fissirostres*, now divided into a number of genera, which form the family *hirundinidae*. This family consists of birds which prey on insects, catching them in the air, and have great powers of flight, now soaring to a great height, now skimming near the surface of the ground or of the water, and wheeling with great rapidity. The bill is short and weak, very broad at the base, so that the gape is wide; the wings are very long, pointed, and more or less sickle-shaped when expanded; the legs are short and weak, and in some—the swifts (q.v.)—more so than those of any other birds. The tail is generally forked. The plumage is close and glossy. The species are very numerous, and widely diffused, being found in almost all countries. Such of them as occur in the colder parts of the world are summer birds of passage, migrating to warmer regions when winter approaches and insects disappear. The family is divided into two groups, *swifts*, which have remarkably long and curved wings, very small weak legs, and short toes, the hinder toes generally directed forward, and *swallows*—some of which are also called *martins*—having wings not quite so long nor so much curved, rather stronger legs, and longer toes, three before and one behind. The COMMON SWALLOW, or CHIMNEY SWALLOW (*hirundo rustica*), exhibits a character common to many other species, in the very long and deeply-forked tail, the two lateral feathers of which far exceed the others in length. The plumage is very beautiful, the upper parts and a band across the breast glossy bluish black, the forehead and throat chestnut, the lower parts white, and a patch of white on the inner web of each of the tail-feathers except the two middle ones. The whole length of the bird is about 8½ in., of which the outer tail-feathers make 5 inches. The nest is made of mud or clay, formed into little pellets and stuck together, along with straw and bents, and lined with feathers. It is open and cup-shaped, and is generally placed in a situation where it is sheltered from wind and rain, as a few feet down an unused chimney, under the roof of an open shed, or in any unoccupied building to which access can be obtained. Two broods are produced in a year. The migration of this and other British species of swallow, now recognized by all naturalists as an unquestionable fact, was formerly the subject of much dispute, and swallows were supposed by many to become torpid in winter, although it was difficult to imagine that if so they should not frequently be found in that state. The geographical range of these species extends over great part of Europe, Asia, and Africa.—The WINDOW SWALLOW, or HOUSE-MARTIN (*H. urbica*, or *chelidon urbica*), is another very common American species, glossy black above, white below, and on the rump; the feet covered with short downy white feathers, which is not the case in the chimney swallow; the tail long, but its outer feathers not remarkably so. The nest is built of mud or clay, like that of the chimney swallow, but is hemispherical, with the entrance on the side, and is attached to a rock, or, very frequently, to the wall of a house, under the eaves or in the upper angle of a window, to the annoyance of housekeepers who prefer the cleanness of their windows to the lively twitter of the birds, and the opportunity of watching their process of nest-building and their care of their young. House-martins congregate in great numbers, as chimney swallows also do before their autumnal migration, and disappear all at once. The house-martin is among the birds of Lapland and Iceland. The only other common British species of swallow is the SAND-MARTIN (*H. riparia*), smaller than either of the preceding, the toes naked, the tail moderately forked, the plumage brown on the upper parts and across the breast, the under parts white. It makes its nest on sandy river-banks, the sides of sand-pits, and other such situations, excavating a gallery of 18 in. or 2 ft., sometimes 3 or even 5 ft. in length, and more or less tortuous, in the extremity of which some soft material is placed for the reception of the eggs. This wonderful excavation is accomplished entirely by the bill of the bird. The floor slopes a little upward from the entrance, so that the lodgment of rain is prevented. The sand-martin is more local than the other British swallows; but it is distributed over most parts of Europe, Asia, Africa, and North America.—The PURPLE SWALLOW, or PURPLE MARTIN (*H. purpurea*), is a North American species, which has in a few instances been known to visit the British islands. The general color, both of the upper and under parts, is shining purplish blue; the wings and tail black. It abounds in North America, and is a universal favorite in the northern parts, being hailed as the harbinger of spring, and frequenting even the streets of towns. It is a very general practice to place boxes near houses for the martins to make their nests in, which are very inartificial, consisting merely of dried grass, leaves, moss, feathers, and the like. Boxes nailed to trees are also readily occupied by the RUFOUS-BELLIED SWALLOW (*H. erythrogaster*), another North American species. But this species, which very nearly resembles the chimney swallow of Britain, makes a nest of mud and fine hay, in the form of the half of an inverted cone, with an extension at the top for one of the parent birds to sit in occasionally. The REPUBLICAN SWALLOW, or CLIFF SWALLOW (*H. fulva*), of North America, makes a nest of mud, in form somewhat like a Florence flask, which it attaches to a rock or to the wall of a house. Hundreds sometimes build their nests in close proximity. The FAIRY MARTIN (*H. ariel*), a small Australian species, also builds a flask-shaped nest, with the mouth below, attaching it to a rock, or to the wall of a house, and numerous nests are often built close together.—Some of the swallows of tropical countries are much smaller than any of the European species.—The East Indian

swallows which make the edible nests (q.v.), belong to the section of the family to which the name swift is given. See *illus., LARKS, ETC., vol. VIII., figs. 13, 14.*

SWALLOWING. THE ACT OF, is accomplished by a set of associated movements which have been divided by physiologists into three stages. In the first stage, the food having been previously duly reduced to a pulp by trituration and insalivation, is carried back by the contraction of various muscles until it has passed the anterior palatine arch. See **PALATE.** So far, the movements are purely voluntary. The second stage now commences, during which the entrance of food into the nasal cavities and larynx is most carefully guarded against by certain reflex (involuntary) actions, which have been only clearly recognized since the introduction of the use of the laryngoscope during the last few years. The tongue is carried further backward, the larynx rises so as to be covered by the epiglottis, which is depressed and lies horizontally, so that its upper border touches the posterior wall of the pharynx. Coincident with these movements, the sides of the posterior palatine arch contract by muscular action, and approach each other like a pair of curtains, so as almost to close the passages from the fauces into the posterior nostrils; the closure being completed by the uvula. A sort of inclined plane is thus formed, and the morsel slips downward and backward into the pharynx, which is raised to receive it. Very little, if any, voluntary action is here exerted. The third stage—the propulsion of the food down the œsophagus—then commences, and this process is effected in the upper part by means of the constrictor muscles of the pharynx, and in the lower, by the muscular coat of the œsophagus itself. At the point where the latter enters the stomach, there is a sort of a sphincter muscle which is usually closed, but which opens when sufficient pressure is made on it by accumulated food, closing again when this has passed. See Carpenter's *Principles of Human Physiology.*

SWALLOW-WORT. See **ASCLEPIAS.**

SWAMMERDAM, JAN, a distinguished naturalist, was b. at Amsterdam, Feb. 12, 1637. Swammerdam, almost from his boyhood, showed the greatest eagerness in the study of natural history. Having entered upon the study of medicine, he particularly occupied himself with anatomy, and continued unremittingly to collect insects, to investigate their metamorphoses and habits, and, by the aid of the microscope, to examine their anatomic structure. He took his degree of doctor of physic at Leyden in 1667, and entered upon the practice of his profession, which his bad health, however, soon compelled him to relinquish. He continued to be chiefly engrossed with anatomy and entomology. His treatise on bees appeared in 1673; a treatise on ephemera in 1675. It is impossible, however, for us to enumerate his many publications, all of which were first published in Dutch, and afterward translated into Latin, and many of them into English, French, and German. Swammerdam's discoveries were very numerous, both in human and comparative anatomy. His skill in using the microscope was very great, and his manipulation of the most minute subjects extremely dexterous. He succeeded in giving distinctness to the forms of very minute viscera, by inflating them with air; a method of his own invention. It is melancholy to add, that Swammerdam, who had always displayed strong religious feelings, and expressed them in his writings, was at last carried away by the fanatical extravagances of Antoinette Bourignon (q.v.), began to think all his former pursuits sinful, and relinquished them for a visionary religious life of mere meditation and devotion. His health rapidly declined, and he died at Amsterdam, Feb. 17, 1680. No man of his time contributed more than Swammerdam to the progress of natural history and physiology. He was the inventor of the method of making anatomical preparations by injecting the blood-vessels with wax, and also of the method of making dry preparations of the hollow organs, now generally employed.

SWAMP ANGEL. An eight-inch rifled Parrott gun used by the Federals in the attack upon Fort Wagner during the civil war. It was named the "Swamp Angel" by the soldiers because it stood midway between Morris and James Islands in an immense marsh of soft black mud sixteen to eighteen feet deep. It was mounted upon a platform of logs raised on piles and was protected by a sand bag parapet and epaulement.

SWAN, *Cygnus*, a genus of birds of the duck (q.v.) family (*anatidæ*), constituting a very distinct section of the family. They have a bill about as long as the head, of equal breadth throughout, higher than wide at the base, with a soft cere, the nostrils placed about the middle; the neck very long, arched, and with 23 vertebra; the front toes fully webbed, the hind toe without membrane; the keel of the breast-bone very large; the intestines very long, and with very long cæca. They feed chiefly on vegetable substances, as the seeds and roots of aquatic plants, but also on fish-spawn, of which they are great destroyers. They are the largest of the *anatidæ*. They have a hissing note like geese, which they emit when offended, and strike with their wings in attack or defense. The common notion, that a stroke of a swan's wing is sufficient to break a man's leg, is exaggerated. The COMMON SWAN, MUTE SWAN, or TAME SWAN (*C. olor*), is about 5 ft. in entire length, and weighs about 30 lbs. It is known to live for at least 50 years. The male is larger than the female. The adults of both sexes are pure white, with a reddish bill; the young (cygnets) have a dark bluish-gray plumage, and lead-colored bill. The bill is surmounted by a black knob at the base of the upper mandible, and has a black nail at its tip. In its wild state, this species is found in the eastern parts of Europe and in Asia; in a half-domesticated state it has long been a common orna-

ment of ponds, lakes, and rivers in all parts of Europe. It is an extremely beautiful bird when seen swimming, with wings partially elevated, as if to catch the wind, and finely curving neck. The ancients called the swan the bird of Apollo or of Orpheus, and ascribed to it remarkable musical powers, which it was supposed to exercise particularly when its death approached. It has, in reality, a soft low voice, plaintive, and with little variety, which is to be heard chiefly when it is moving about with its young. The nest of the swan is a large mass of reeds and rushes, near the edge of the water, an islet being generally preferred. From 5 to 7 large eggs are laid, of a dull greenish-white color. The female swan sometimes swims about with the unfledged young on her back, and the young continue with their parents until the next spring. The swan is now seldom used in Britain as an article of food, but in former times it was served up at every great feast, and old books are very particular in directions how to roast it and to prepare proper gravy.—The POLISH SWAN (*C. immutabilis*), of which flocks have occasionally been seen in Britain in winter, differs from the common swan in its orange-colored bill, in the smaller tubercle at its base, and in the shape and position of the nostrils. The young are also white, like the adults. It belongs chiefly to the north-eastern parts of Europe. Many naturalists regard it as the true wild state of the common swan.—The WHISTLING SWAN, ELK SWAN, or HOOPER (*C. ferus*), abounds in the northern parts of Europe and Asia. Flocks frequently visit Britain in severe winters, and their migrations extend as far s. as Barbary. A few breed in the Orkney islands, but the greater number in more northern regions. The size is about equal to that of the common swan, and the color is similar, but the bill is more slender, is destitute of knob, and is black at the tip, and yellow at the base. This bird is frequently brought to the London market. The names hooper and whistling swan are derived from the voice. The anatomical differences between this species and the common swan are more considerable than the external, particularly in the double keel of the breast-bone forming a cavity which receives a long curvature of the wind-pipe.—BEWICK'S SWAN (*C. Bewickii*), another native of northern Europe, is more rare in Britain, but flocks are sometimes seen. It is about one-third smaller than the whistling swan.—The AMERICAN SWAN (*C. Americanus*) nearly resembles Bewick's swan. It breeds in the northern parts of North America, and its winter migrations only extend to North Carolina.—The TRUMPETER SWAN (*C. buccinator*) is another American species, breeding chiefly within the Arctic circle, but of which large flocks may be seen in winter as far s. as Texas. It is rather smaller than the common swan.—The ancients spoke of a black swan proverbially as a thing of which the existence was not to be supposed, but Australia produces a BLACK SWAN (*C. atratus*), rather smaller than the common swan, the plumage deep black, except the primaries of the wings, which are white. The bill is blood-red. It has been introduced into Britain, and breeds freely. It is very abundant in some parts of Australia.—The BLACK-NECKED SWAN (*C. nigricollis*) is a South American species, as is the DUCK-BILLED SWAN (*C. anatoides*), the smallest of all the species, white, with black-tipped primaries, common about the strait of Magellan. It is a curious circumstance that the black color appears more or less in all the species of the southern hemisphere, and in them alone, except in the approach to it made in cygnets.

Swans, according to the law of England, are birds royal. When they are found in a partially wild state, on the sea and navigable rivers, they are presumed to belong to the crown, and this is one of the prerogatives of the crown, though it may be delegated to a subject. The royal birds generally have a mark on them, and the king's swan-herd once was an important person. A subject is not entitled to have a swan-mark unless he has a qualification of land, and has a grant from the crown, or prescriptive use.

SWAN, JAMES, 1754-1831; born Scotland; came to this country when a boy and engaged in business in Boston. He took part in the popular agitation leading to the revolution, was one of the Boston "tea party," and aide to Warren at Bunker Hill. He afterward served as member of the Massachusetts legislature and adjt. gen. of the state. After the war he made a large fortune in Paris, and, 1795-98, visited this country and spent money profusely. In 1815, then being in Europe, he was arrested on a civil suit, and, refusing to settle, lived for 15 years in Ste. Pelagie prison, Paris, in the most magnificent style. He published a number of pamphlets on such subjects as the slave trade (1772), fisheries, the commerce of France and the United States, agriculture, and manufactures.

SWANN, THOMAS, b. Va. in 1805; educated at the university of Virginia; afterwards studied law at Washington, and in 1834 settled in Baltimore, where the greater part of his life was spent. He was president of the Baltimore and Ohio railroad, 1847-53, and was connected with other railroads. In 1858 he was elected mayor of Baltimore. He warmly supported the union during the civil war, and in 1864 was chosen governor of the state. In 1868 he was elected to congress and served ten years. He d. 1883.

SWAN-PAN. (Shwan-Pan). The Chinese Abacus. It consists of an oblong frame holding 10 parallel wires. These wires are unequally divided, with four beads in the longer, and two in the shorter portions of the instrument, and embraces numbers as far as *ten billions*. In representing numbers upon it, the *swan-pan* is held in a vertical position, thus bringing the wires into horizontal lines. The values of the beads increase in descending, the greater numbers being placed underneath the smaller. As the decimal

system applies to the Chinese coins, and to all their measures of weight, length, and capacity, the *swan-pan* is adapted to arithmetical operations of every kind.

SWAN'SEA (Welsh, *Abertawy*), a market t., municipal and parliamentary borough, and sea-port of the county of Glamorgan, South Wales, stands on the right bank and at the mouth of the Tawe, 60 m. w.n.w. of Bristol. The harbor is formed by means of piers of masonry projecting from either side of the mouth of the Tawe into Swansea bay, a wide inlet of the Bristol channel. The vast resources of the coal-field in the midst of which the town is situated began to be explored and turned to commercial account about the year 1830; and since that time the progress of Swansea has been so rapid that it is now the most important town in South Wales. The houses and public edifices and institutions are of recent erection. A good public hall was erected in 1864, and a spacious and well arranged infirmary in 1867. Swansea is the chief seat of the tinplate trade of England, and probably the most important copper smelting and refining center in the world. No copper is found in this part of Wales, but the coal obtained in the vicinity is peculiarly adapted for smelting purposes, and great quantities of ore are brought hither to be smelted, not only from the copper-mines of Britain, but from Cuba and the west coast of South America. In the immediate vicinity of the town, there are smelting-works, in which many thousands of tons of copper, copper ores, silver ores, and zinc ores are smelted annually. Of the whole amount of copper manufactured in Great Britain, seven-eighths are smelted at Swansea and in its immediate vicinity. In 1859, a large floating dock, 13 acres in extent, was opened by the side of the harbor. Its north side is lined with warehouses. In 1881 a new dock was finished at a cost of \$1,500,000. Pop. '91, 90,349.

SWARGA is the paradise of the Hindu god, Indra (q.v.). It is the residence of some of the inferior gods and deified mortals, who there rest in the shade of the five wonderful trees—*Mandâra*, *Pârjâtâ*, *Santâna*, *Kalpavriksha*, and *Harichandana*, drink *Amrita*, or the beverage of immortality; and enjoy the music of the *Gandharvas*, and the dancing of the heavenly nymphs, the *Apsarasas*.

SWARMING, a peculiar mode of reproduction which has been observed in some of the *confervaceæ*, *desmidiæ*, etc. The granules which form the green matter in the plant, or in one of its joints, become detached from each other, and move about in the cell with great rapidity. The external membrane swells in one point and finally bursts there, when the granules escape into the surrounding water to become new plants. At first they issue in great numbers, but those which remain last move about within their cell for a long time before they find the way out. Their motion is supposed to be due to cilia.

SWAYNE, WAGER, b. Columbus, Ohio, 1834; son of Judge Noah H.; graduate of Yale college, 1856; studied law and commenced practice in his native town. In the civil war he was major 43d Ohio infantry, 1862; raised to colonel after effective service at Iuka and Corinth. He served through the Georgia campaign, lost a leg at Salka-hatchie, where he greatly distinguished himself, and was made maj.gen., 1863, and assigned to the commission on refugees, freedmen, and abandoned lands. He was commissioned col. 45th infantry, 1866; retired, 1870.

SWE'ABORG, or SVE'ABORG, a great Russian fortress in the principality of Finland, and government of Viborg, sometimes called "the Gibraltar of the north," protects the harbor and town of Helsingfors, from which it is only 2 m. distant. The fortifications extend over seven islands, the *Nylandischen Skären*, but the grand central point is the island of Vargö. The islands are connected with each other by means of bridges, and between two of them lies the single narrow entrance to the harbor, which can hold from 70 to 80 ships of the line. Swe'aborg has a civic pop. of about 3,000, the greater part of whom are manual-laborers, ship-carpenters, and traders, and a garrison of some 5,000 men (including women and children). During the Crimean war the Anglo-French fleet

in the Baltic made a reconnoissance of the place, and bombarded it for two days (Aug. 9 and 10, 1855), but found the defenses too formidable to be reduced,

SWEARING, PROFANE, according to the law of England, is an offense for which the party may be convicted by a justice of the peace according to a scale of penalties. A day laborer, common soldier, sailor, or seaman forfeits 1s per oath; every other person under the degree of a gentleman, 2s; and every person above the degree of a gentleman, 5s—for a second offense double these sums; for a third treble, etc. If the cursing take place in the presence of a justice of the peace, the latter may convict the prisoner then and there, without further process. Laws against profane swearing were general in the colonies of America, and in many instances were enforced with great severity. Similar laws remain on the statute books of almost all the states, but the enforcement of these laws is rare. These laws, however, never made, as did the Eng. laws on this point, any distinction as to classes. There were, however, in some of the New England states distinctions made in the punishment for different forms of profane swearing.

SWEAT (A. S. *swat*, Sansc. *svaidas*, Lat. *sudor*; Gr. *hydor*, moisture; Lat. *ud(us)* = wet), or perspiration. The nature, composition, and uses of this fluid in the normal state have been sufficiently noticed in the article **SKIN**. It may be additionally remarked, in connection with the physiology of sweat, that the composition of this fluid varies materially according to the part of the body from which it is secreted. Thus Funk found the sweat of the feet was richer in fixed salts than that of the arm, in the ratio of 5 to 3; and Schotten found a considerable preponderance of potassium in the former. In the negro, Dr. Copland and other observers have found that both the gaseous exhalations from the skin, and the solid matters contained in the sweat, were much greater than in the white races. It has been shown in the article **SKIN** that the sweat-glands, like the lungs and kidneys, act as depurating organs, and separate and carry off effete matters from the blood. This eliminative action of the skin is modified in various diseases; in some cases being diminished, as in the early stage of fevers, in inflammations before suppuration commences, in scurvy, diabetes, sunstroke, etc., while it is more or less increased in the sweating stage of ague, in acute rheumatism, in Asiatic cholera, in certain adynamic fevers, in the advanced stages of pulmonary consumption, in the formation of matter in internal parts, etc. The sweat is naturally acid in health, but in prolonged sweating the secretion becomes neutral, and finally alkaline. Little is known with certainty regarding the coloring matters of sweat. In cases of jaundice, the sweat sometimes communicates a yellow tinge to the body-linen; and instances of blue, red, and bloody sweat are on record. Cases of sweat of these colors are recorded in Simon's *Animal Chemistry* (Syd. Soc. Trans., (London, 1845), vol. ii., p. 110. Cases of unilateral sweating, stopping abruptly at the middle line, have been occasionally noticed, especially in aneurism of the aorta.—See Gairdner's *Clinical Medicine*, page 557. Dr. Drutt has pointed out the use of hot water as a remedy for profuse perspiration. He has found it serviceable in (1) oversweating in good health and hot weather; (2) undue sweating in special parts of the body, as the hands, feet, or armpits; (3) true hectic; and (4) ordinary night sweats in phthisis not preceded by hectic symptoms. To be of any service, the water must be applied at as great a heat as the patient can possibly bear (see his paper on this subject in the *Medical Times* for March 4, 1865). For a very interesting and learned discussion on our Saviour's bloody sweat during his passion, the reader may consult Stroud *On the Physical Cause of the Death of Christ*, and Trusen's chapter *Von dem Blutschweisse Christ* in his *Darstellung der Biblischen Krankheiten*, 1843.

SWEATING SICKNESS, **THE**, is the term given to an extremely fatal epidemical disorder, which ravaged Europe, and especially England, in the 15th and 16th centuries. It derives its name "because it did most stand in sweating from the beginning until the endyng," and "because it first beganne in Englande, it was named in other countries the Englishe sweat."—*The Boke of Thon Caius against the Sweating Sicknes*. It first appeared in August, 1485, in the army of Henry VII., shortly after his arrival at Milford in South Wales from France, and in a few weeks it spread to the metropolis. It was a violent inflammatory fever, which, after a short rigor, prostrated the powers as with a blow; and amid painful oppression at the stomach, headache, and lethargic stupor, suffused the whole body with a fetid perspiration. All this took place in the course of a few hours, and the crisis was always over within the space of a day and night. The internal heat which the patient suffered was intolerable, yet every refrigerant was certain death. "*Scarce one amongst a hundred that sickened did escape with life.*"—Holinshed, vol. iii. p. 482. Two lord mayors of London and six aldermen died within one week; and the disease for the most part seized as its victims robust and vigorous men. It lasted in London from the 21st (some authorities say the middle) of September to the end of October, during which short period "many thousands" died from it. The physicians could do little or nothing to combat the disease, which at length was swept away from England by (as many supposed) a violent tempest on New Year's day. The disease did not re-appear till the summer of 1506, when it broke out in London, but does not seem to have occasioned any great mortality. In July, 1517, it again broke out in London in a most virulent form; it being so rapid in its course that it carried off those who were attacked in two or three hours. Among the lower classes, the deaths were innumerable, and the ranks of the higher classes were thinned. In many towns a third, or even a half of the inhabitants were swept away. On this occasion, the epidemic lasted about six months. In May, 1528—the year in which the French army before Naples was de-

SWEDEN & NORWAY

stroyed by pestilence, and in which the putrid fever known as *Trousse-galant* decimated the youth in France—the sweating sickness again broke out in the metropolis, spread rapidly over the whole kingdom, “and fourteen months later, brought a scene of horror upon all the nations of northern Europe scarcely equaled in any other epidemic.”—Hecker's *Epidemics of the Middle Ages*, (Syd. Soc. Trans.), p. 238. How many lives were lost in this epidemic, which has been called by some historians the *great mortality*, is unknown; but the mere fact that the king (Henry VIII., who, whatever his faults, was never accused of cowardice) left London, and endeavored to avoid the disease by continually traveling, shows the general feeling of alarm that existed. In the following summer (July 25, 1529), having apparently died out in England, it appeared in Germany, first at Hamburg, where it is recorded that 8000 persons died of it, and shortly after at Lubeck, Stettin, Augsburg, Cologne, Strasburg, Hanover, etc. In September, it broke out in the Netherlands, Denmark, Sweden, and Norway, whence it penetrated into Lithuania, Poland, and Livonia. By January of the following year, after an existence of three months, it had entirely disappeared from all these countries. For three-and-twenty years the sweating sickness totally disappeared, when for the last time (April 15, 1551) it burst forth in Shrewsbury. The banks of the Severn seemed to be the focus of the malady, which was carried from place to place by poisonous clouds of mist. There died within a few days 960 of the inhabitants of Shrewsbury, the greater part of them robust men and heads of families. The disease spread rapidly over the whole of England, but seems to have disappeared by the end of September. The deaths were so numerous, that one historian (Stow) states that the disorder caused a *depopulation* of the kingdom. The very remarkable observation was made in this year, that the sweating sickness uniformly spared foreigners in England, and on the other hand, followed the English into foreign countries. The immoderate use of beer among the English was considered by many as the principal reason why the sweating sickness was confined to them. “By the autumn of 1551,” says Hecker, “the sweating sickness had vanished from the earth; it has never since appeared as it did then and at earlier periods; and it is not to be supposed that it will ever again break forth as a great epidemic in the same form, and limited to a four-and-twenty hours' course; for it is manifest that the mode of living of the people had a great share in its origin, and this will never again be the same as in those days.”—*Epidemics of the Middle Ages* (Syd. Soc. Trans.), p. 306.

SWEDEN, *Sverige*, the eastern portion of the Scandinavian peninsula, governed with Norway by a single King. It is situated in 55° 20'–69° 3' n. lat., and 11°–24° e. long., and is bounded on the n. and w. by Norway; on the extreme s.w. and s. by the Cattegat, which separates it from Denmark; on the s.e. and e., as far as 66° n. lat., by the Baltic and the gulf of Bothnia; and from thence to the extreme n. by Russia. The area is 172,876 sq. m.; and the population was estimated, Dec. 31, 1895, at 4,919,260. Its length is 969 m., and its greatest width from 150 to 280 miles. Sweden is divided into three provinces—viz., Norrland, the largest and most northern; Sweden Proper, or *Svea-rike* (land of the Swedes), in the center; and Götland, or *Göta-rike* (land of the Goths), to the south. The following are the areas and populations of the 25 län into which the provinces are subdivided:

| Län. | Area: Eng. Sq. Miles. | Population, Dec. 31, 1890. | Population, Dec. 31, 1895. |
|---------------------------------|--------------------------|-------------------------------|-------------------------------|
| Stockholm (rural district)..... | 3,015 | 152,715 | 157,457 |

In 1878 Sweden ceded her only colony, St. Bartholomew, to France (to which country it once belonged) on payment of the purchase-money agreed on. See BARTHOLOMEW, St.

Unlike Norway, Sweden possesses few high mountains, but contains numerous lakes of large dimensions. The coast skirting the Baltic, and the adjoining islands, are for the most part low and sandy, although in some parts, as in the vicinity of the outlet of lake Maelar into the sea (in about 58° n. lat.), the shores are steep; and on the s. and w. coast, the generally low, alluvial lands are replaced by more rocky formations.

In the northern parts the land rises gradually from the gulf of Bothnia to the Kjölen range, belonging to the great Norwegian Fjeldmark, which constitutes the true watershed and natural boundary between Sweden and Norway. South of 62° n. lat., the slope is directed southward, attaining its lowest level in the vicinity of the three great lakes of Wener, Maelar, and Hjelmar, which, together with the great Wetter Lake, nearly intersect the country from e. to w.; and s. of these great inland waters, the surface is in general level, though ranges of high ground and detached hills occur.

Sweden may be considered to be divided into three distinct parts—viz., the northern or alpine region, the central or lake district, and the southern or mining district. The extreme s. includes the only level and fertile tract, in which wheat can at all times be advantageously and extensively cultivated. The lakes of Sweden have been computed to cover nearly $\frac{1}{4}$ th of the entire area of the country. The largest are Lake Wener (q.v.), Lake Wetter (q.v.), and the Maelar Lake (q.v.). The rivers are generally short and rapid, and only made navigable by art. The largest is the Angermann Elv, which flows into the gulf of Bothnia. The Cattogat is connected with the Baltic by means of an admirable system of canals, etc.

Natural Products, etc.—The heat of the summer, which is scarcely separated from the cold of the winter by either spring or autumn in the extreme northern districts, enables the inhabitants to cultivate barley, which is reaped within two months of the time of its sowing, although even the hardier cereals, as oats and rye, will not ripen above the parallel of 66° n. lat. Indeed, the climate of Sweden generally is unfavorable to the growth of grain, the annual yield of which frequently falls short of the wants of the population. The principal articles of cultivation are, in addition to the various cereals, potatoes, hemp, flax, tobacco, and hops, which are generally grown in sufficient quantities for home consumption. The forests are of great extent, covering nearly one-fourth of the entire surface, and rising at some spots to an elevation of 3000 ft. above the level of the sea. The birch, fir, pine, and beech are of great importance, not only for the timber, tar, and pitch which they yield, but also from their supplying charcoal and firewood. Above the parallel of 64°, stunted bushes, berries, dwarf-plants, and lichens are the only forms of vegetation to be met with. The common fruit-trees, as cherries, apples, and pears, grow as far north as 60°, but the fruit seldom comes to great perfection except in the southern provinces; cranberries and other berries abound, however, in all parts of the country. Bears and beavers, which were formerly often met with, are becoming scarce; but wolves, lynxes, foxes, martens, squirrels, eagles, reindeer, in the Lappmarks, etc., are still common; while the elk and deer are found in some of the forests, which abound in hares, woodcock, blackcock, and various other kinds of small game; and lemmings (q. v.) occasionally descend from the mountains in large numbers, and lay waste the low country. The waters along the coast yield a great abundance of fish, many different kinds of sea and fresh-water fish being brought to market. The mineral products of Sweden, which are extremely rich, include some gold and silver (which, however, do not pay the cost of working), copper in abundance, iron of the finest quality, alum, vitriol, marble, sulphur, lead, plumbago, cobalt, nickel, zinc, and some coal.

Industries.—In almost all branches of production there was a remarkable increase between the year 1866 and 1896. In respect to agriculture, the principal occupation of the inhabitants, the cultivated area in 1866 was 2,500,000 hectares (a hectare being equal to 2.471 acres), while in 1896 it was 3,500,000 hectares. In the associated industry of dairy farming there has been an equally great increase, and this branch of production has become one of the most important in Sweden. To illustrate its increase, while Sweden at the beginning of this period was an importer of butter to the extent of over 11,000,000 pounds a year, at the end of it she was an exporter to the extent of over 55,000,000 pounds. Not only did the number of live stock increase during this period of thirty years, but the quality of the breeds was greatly improved. The output of pig-iron doubled during the same interval and that of iron ore quadrupled. A still more remarkable advance was that of the steel industry, which, during the decade 1860–70, produced only 7,000 tons a year, while in 1896 the output was 170,000 tons. The number of employees engaged in industries was more than three times as great at the end of the period as at the beginning, and foundries and mechanical works, sugar works and refineries, paper mills, etc., all showed a considerable increase in the value of their output. The timber trade affords employment to large numbers of the inhabitants, and is one of the most important of Swedish industries. Its advance has kept pace with the improvement in other trades. The tonnage of sailing-vessels in the mercantile navy has increased, but not to the same extent as that of the steamships, whose tonnage in 1896 was more than twelve times as great as in 1866. The building of railroads has also

greatly advanced, the mileage for 1866 being 932, and for 1896, 6214. Considering the smallness of her population, this mileage is very considerable for Sweden. In 1896 preparations were made for an exhibition to be held at Stockholm in the spring of the following year. This was the fourth international exhibition held in Scandinavia, the first having taken place also at Stockholm in 1866. The countries participating in the exposition of 1897 were Sweden, Norway, Denmark, Finland and Russia, and nearly all European countries planned to contribute to the art exhibition.

Exports and Imports.—Of agricultural products Sweden exports only a small quantity of grain, with the exception of oats, the exports of which have been considerable. For wheat, rye, barley, wheat flour and rye flour, she has been largely dependent upon foreign countries. According to the report for the year ending Sept. 30, 1896, she exported a considerable number of neat cattle, sheep and hogs, and her exports of pork considerably exceeded her imports. The importation of butter is very large and has increased in value from over \$5,000,000 in 1886-87 to over \$12,000,000 in 1895-96. In 1896 the statistics placed Sweden at the head of all the wood-exporting countries in the world. The chief articles of import from the United States to Sweden are wheat, maize, wheat flour, leather, cotton, petroleum, machinery, pork, syrup, and molasses. In respect to petroleum, the United States has had a formidable competitor in Russia, and the development of American trade has been retarded by the lack of trade steamship communication.

Gold is fixed by law as the metallic standard of Sweden, and it forms the basis of the coinage system. Formerly Sweden had a silver standard, the chief coin or unit being equivalent to about four kronor of the present coin, but by the law of May 30th, 1873, the gold standard was adopted, from fear of a constant tendency on the part of silver to depreciate. Nominal wages are much lower than in the United States; the average wages for men, according to the agricultural society's report on the rates among farm laborers in 1894, was \$109.34, or 408 kronor. The value of the krona or crown in United States money, according to the official report of the United States treasury in 1897, was 26.8 cents.

Revenue, etc.—Sweden levies a tax on imports, and this supplies the chief source of revenue. According to the budget estimate for 1897, the national income from the customs was one-third of the total revenue. Next in importance was the impost on spirits, etc., and a large return came from the public domains, railways, and the tax on land. About one-third of the railways belong to the state. The debt of Sweden amounted in 1896 to 287,505,967 kronor, all of which was incurred to meet the expense of building and carrying on the railways. The receipts from the railways amounted to about two-thirds of the interest on this debt. For an account of the army and navy of Sweden, see the articles NAVIES, MODERN and ARMIES, MODERN.

Form of Government.—Sweden is a hereditary and constitutional monarchy, based on the fundamental law of 1809, by which it was decreed that the succession should be in the male line; that the sovereign should profess the Lutheran faith; and have sworn fidelity to the laws. The diet, which meets every year, and remains sitting for three or four months, is composed of two chambers, which are both elected by the people. The first chamber consists of 150 members, who receive no payment, and are elected for nine years, their number being, however, dependent upon that of the population. They must be possessed of an income of about £223, and have attained the age of 35. The second chamber is composed of 230 members, elected for three years, on a lower scale of qualification as to property and age; and receiving payment for their attendance during each session of the diet, and for their traveling expenses. Election to both chambers is by ballot. The diet exercises a strict control over the expenditure of the revenue, fixes the budget, and has power to take cognizance of the acts of the ministers and crown officers. The king's person is inviolable, and he can exercise a veto on the decrees of the diet. He is the supreme head of the law courts, nominates to all appointments, can declare war, make peace, and conclude foreign treaties. He is assisted by a council of state composed of 10 members, who are responsible to the diet.

Law, etc.—The administration of the law is independent of the state, and presided over by the chancellor of justice, *justitie kansler*, appointed by the king, and an attorney-general, *justitie ombudsman*, appointed by the diet.

Sweden is divided administratively into 25 *läns*, presided over by chief magistrates, and subdivided into 117 *fögderin*, and 520 *länsmans* districts. There are 90 chief towns (*städer*), only a limited number of which have the right of trading with foreign ports, and 19 market-towns (*Köpingar*). Besides Stockholm, the capital (*q. v.*), only two towns, Göteborg (114,527) and Malmö (52,470), had a pop. of more than 50,000 in 1895. Next in rank came Norrköping, with 36,075; Gefle, with 25,569; and Karlskrona, with 22,496 inhabitants. Upsala, a cathedral and university town, which is the most interesting spot in the kingdom, as the original seat both of Christianity and of the ancient Odinic faith, has a pop. of 21,428.

Religion, etc.—The state religion is Lutheran. The affairs of the church are administered by 1 archbishop (of Upsala) and 11 bishops. According to the census of 1890, there were 4,735,218 Evangelical Lutherans and 44,378 Protestant dissenters.

Education, etc.—Education is universally diffused among the Swedes by the agency of *fasta* (regular) and *flyttande* (ambulatory) schools in all the country districts. Public

instruction is compulsory for all children, and the cost is defrayed by the nation. Ample means are supplied for a higher form of instruction in the *läroverk* or gymnasia of the towns, and at the universities of Upsala and Lund. The Karolinska institute at Stockholm is the medical college of Sweden; and there are numerous technical, military, and other special collegiate institutions in the principal towns of the kingdom. The transactions of the two learned societies, the "*Svenska Vetenskaps Selskap*," and the "*Svenska akademie*," afford honorable testimony to the advanced condition of scientific inquiry in Sweden. There are well equipped libraries at Stockholm, Upsala, and Lund. That of Upsala is contained in a special building, *Carolina Rediviva*, to which is attached a botanical garden arranged on the Linnæan system.

History.—The legendary history of Sweden forms part of Scandinavian history. When we first hear of Sweden the country was inhabited by numerous tribes, kindred in origin but politically separate. Two principal groups, however, are recognizable—*Goths* in the south and *Svedes* in the north. These possessed in common a national sanctuary, the temple of Upsala, which laid the basis of a later unification, for gradually the royal chieftains of Upsala extirpated the inferior princes, the *Härads* and the *Fylkis*. Ingiald Illrada, the last ruler of the old royal family of the Ynglingar, who drew their origin from Njord, sought to establish a single government in Sweden, and perished in the attempt. To the Ynglingar followed in Upland the dynasty of the *Skioldungar*, which claimed to be descended from Skjold, son of Odin. Erik Edmundsson, who belonged to this dynasty, is said to have acquired the sovereignty of the whole of Sweden about the end of the 9th century. The dawn of Swedish history (properly so called) now begins, and we find the Swedes constantly at war with their neighbors of Norway and Denmark, and busily engaged in piratical enterprises against the eastern shores of the Baltic. See NORMANS and RUSSIA. Efforts to introduce Christianity (see ANSGAR) were made as early as 829 A.D., but it was not till 1000 A.D. that Olof Skötkonung, the Lap-king, was baptized, nor did the struggle between heathenism and the new religion cease till the burning of the temple of Upsala in the reign of Inge (1080-1112). In 1155 Erik, surnamed The Saint, gave a powerful impetus to the diffusion of Christian doctrines by building churches and founding monasteries. He undertook a crusade against the pagan Finns, and, having compelled them to submit to baptism, and established Swedish settlements among them, he laid the foundation of the union of Finland with Sweden. Erik's defeat and murder in 1160 by the Danish prince Magnus Henriksen, who made an unprovoked attack upon the Swedish king, was the beginning of a long series of troubles, and during the following 200 years, one short and stormy reign was brought to a violent end by murder or civil war only to be succeeded by another equally short and disturbed. At length, in 1389, the throne was offered by the Swedish nobles to Margaret, queen of Denmark and Norway, who, having gladly availed herself of the opportunity thus opened to her of uniting the three Scandinavian crowns into one, threw an army into Sweden, defeated the Swedish king Albert of Mecklenburg, who on the deposition of his maternal uncle Magnus had been called to the vacant throne, and by the union of Calmar in 1397 brought Sweden under one joint scepter with Denmark and Norway. In 1523 Sweden emancipated itself from the union with Denmark, which during the reigns of Hans and his son Kristian II. (see DENMARK) had become hateful to the Swedes, and rewarded its deliverer, young Gustaf Vasa (see GUSTAVUS I.), by electing him king and declaring its independence of Denmark. Gustaf Vasa found an empty treasury, a kingdom exhausted by war, a haughty nobility and clergy (who arrogated the right of electing the sovereign, and who claimed exemption from all imposts), and a people overburdened with taxation and bad government and divided in regard to religion. On his death in 1560 he left to his successor a hereditary and well-organized kingdom (in which the power of the nobles had been circumscribed, and that of the clergy broken, by the abrogation of Catholicism and the firm establishment of the reformed church under the jurisdiction of the state), a full exchequer, a standing army, and a well-appointed navy. Trade, manufactures, art, learning, and science owed their advancement in Sweden to this patriotic king.

The colossal labors of the great Vasa in raising a semi-barbarous state to an honorable place among the civilized monarchies of Europe, were rendered almost useless by the crimes and misfortunes of his son and successor, Erik XIV., whose high intellectual powers were clouded by a wayward and revengeful nature, leading him finally to insanity. His cruelties and excesses led to his deposition in 1568, when his younger brother Johan ascended the throne, which he occupied for nearly a quarter of a century, dying in 1592, after a stormy reign, stained by the cruel murder of his unfortunate brother Erik, and distracted by the internal dissensions arising from his attempts to force Catholicism on the people, and to carry on war with the Danes, Poles, and Russians. Johan's son and successor, Sigismund, who had been elected king of Poland through the influence of the relatives of his Polish mother, after a short and stormy reign of eight years, which were spent in attempting to restore Catholicism in Sweden, was compelled by the diet to resign the throne in 1599 to his uncle Karl, the only one of Gustaf Vasa's sons who inherited any share of his legislative and administrative talents. The policy of Karl IX., was to encourage the burgher classes at the expense of the nobility; and by his successful efforts to foster trade—in furtherance of which he laid the foundation of

Göteborg and other trading ports—develop the mineral resources of the country, and reorganize the system of Swedish jurisprudence, he did much to retrieve the calamitous errors of his predecessors. The deposition of Sigismund gave rise to the Swedo-Polish war of succession, which continued from 1604 to 1660; and on the death of Karl in 1611, his son and successor, the great Gustavus Adolphus, found himself involved in hostilities with Russia, Poland, and Denmark. By the ability of his minister, Oxenstierna, the young king was soon enabled to conclude treaties of peace with his northern neighbors, and to place the internal affairs of his kingdom in order (see GUSTAVUS II.); and although he justly ranks as one of the greatest military commanders of his age, the extraordinary number of benefits which he conferred on every department of the administrative system of Sweden, entitle him to still greater renown as the benefactor of his native country. His death in 1632, on the field of Lützen, would have proved an irreparable calamity to Sweden, had not the able administration of Oxenstierna, during the minority of Gustavus's daughter, Christina, maintained the renown of the Swedish arms abroad, and the political reputation of the country among other states. The reign of Christina (q.v.) was disastrous in every act but that of her abdication. The short reign of Karl X. was occupied in generally unsuccessful wars against Poland and Denmark; while the minority and long rule of his son, Karl XI.—from 1660 to 1697—was characterized by success abroad, and in the augmentation of the regal power, which was declared by an act of the diet to be absolute. His son Karl, known to us as Charles XII. (q.v.), succeeded, at the age of 15, to the power and dominions which his father's abilities had consolidated, but which, notwithstanding his own brilliant genius, he so deeply imperiled by his insatiable ambition, that at his untimely death in 1718, at the siege of Frederikshald, after a brilliant career of glorious but checkered military achievements, he left his country overwhelmed with debts, and disorganized by prolonged misrule. With him the male line of the Vasas expired, and his sister and her husband, Frederick of Hesse-Cassel, were called to the throne by election, but were the mere puppets of the nobles, whose rivalries and party dissensions plunged the country into calamitous wars and almost equally disastrous treaties of peace, and, under the leadership of the two great factions of the "Hats," or French party, and the "Caps," or Russian party, demoralized all ranks of society. The weak Adolphus Frederick of Holstein-Gottorp, who was called to the throne on the death of Frederick in 1751, and died in 1771, did little to retrieve the evil fortunes of the state; but his son, Gustavus III. (q.v.) (1771-92), skillfully turned to account the general dissatisfaction of the people with the nobles, to destroy the factions of the Hats and Caps, and to recover the lost power of the crown. His extravagance, dissoluteness, and insincerity detracted, however, from his merits as a ruler, and raised up numerous enemies against him, through whose agency he was assassinated in 1792. His son and successor, Gustavus IV. (q.v.) lacked the ability to cope with the difficulties of the times, and after suffering in turn for his alliance with France, England, and Russia, was forcibly deposed in 1809, and obliged to renounce for himself and his direct heirs the crown in favor of his uncle, Charles XIII., who saw himself compelled at once to conclude a humiliating peace with Russia by the cession of nearly a fourth part of the Swedish territories, with 1½ million of inhabitants. The early part of the reign of Charles, who was childless, was troubled by domestic and foreign intrigues to regulate the choice of an heir to the throne; and when, under the erroneous idea of conciliating Napoleon, the dominant party in Sweden elected General Bernadotte to the rank of crown prince, the latter assumed the reins of government, and by his steady support of the allies against the French emperor, secured to Sweden at the congress of Vienna, the possession of Norway, when that country was separated from Denmark. Under the able administration of Bernadotte, who, in 1818, succeeded to the throne as Charles XIV., the united kingdoms of Sweden and Norway made great advances in material prosperity and political and intellectual progress; and although the nation at large entertained very little personal regard for their alien sovereign, his son and successor, Oscar (1844-59), and his grandsons, the late king, Charles XV., and the present king, Oscar II., who came to the throne in 1872, won a large share of the affections of the Swedes, though the Norwegians are less loyal, owing to their jealousy of the predominance of Sweden, which in 1894-95 threatened to bring on a civil war.

SWEDENBORG, EMANUEL, was b. in Stockholm, Jan. 29, 1688, and died in London, Mar. 29, 1772. His father was Jesper Svedberg, subsequently bishop of Skara. Swedenborg's lifetime divides itself into two distinct periods; the first, ending with his 55th year, was given to business, science, and philosophy; the second, of nearly 30 years, was consecrated to theology and spiritualism. Swedenborg was educated at Upsala, and traveled for four years in England, Holland, France, and Germany. On his return to Sweden, he was appointed by Charles XII. to an assessorship of mines; and rendered some service to that monarch as military engineer. The Swedenborg family was ennobled in 1719, and the name changed from Svedberg to Swedenborg. Swedenborg is sometimes styled count and baron, but erroneously; he was neither, though he had a seat in the Swedish house of nobles. His mind at this time was busy with mechanical and economical projects. He published short treatises on algebra, giving the first account in Sweden of the differential and integral calculus; on a mode of find-

ing the longitude at sea by the moon; on decimal money and measures; on the motion and position of the earth and planets; on the depth of the sea, and greater force of the tides in the ancient world; on docks, sluices, and salt-works; and on chemistry as atomic geometry. In 1724 he was offered the professorship of mathematics at Upsala, which he declined from a dislike of speculative science. Abandoning his desultory studies, he remained silent for eleven years, and devoted himself to the duties of his assessorship and to a systematic description of mining and smelting, and the construction of a theory of the origin of creation. The result appeared at Leipsic in 1734, in three massive folios, beautifully illustrated, entitled *Opera Philosophica et Mineralia*. The second and third volumes describe the manufacture of copper, iron, and brass, and contain an exhaustive record of the best methods in use in last century. The first volume, entitled *Principia, or the First Principles of Natural Things, being new Attempts toward a Philosophical Explanation of the Elementary World*, is an elaborate deduction of matter from "points of pure motion produced immediately from the infinite." This was followed in 1734 by a treatise on *The Infinite, and the Final Cause of Creation; and the Intercourse between the Soul and the Body*, carrying the doctrine of the *Principia* into higher regions, and resolving the soul into points of motion, and one in substance with the sun. Dissatisfied with his conclusions, he determined to track the soul to its inmost recesses in the body. His studies in human anatomy and physiology with this end in view, appeared as *Economia Regni Animalis*, in two volumes, 1741, and as *Regnum Animale*, in three volumes, unfinished, 1744-45. At this point, his course was arrested, and he entered on his career as seer, by which he is known to fame. The particulars of the transition lay in obscurity until 1858, when G. E. Klemming, royal librarian, Stockholm, discovered Swedenborg's diary, kept in 1744. It contains the record of a variety of dreams, visions, and strange communings. After that date, he professed to enjoy free access to heaven and hell. He resigned his assessorship in 1747, that he might devote himself to his office of seer. In 1749 he made his first public appearance in his new character in the issue in London of the *Arcana Cœlestia*, completed in 1756 in eight quartos. His life henceforward was spent between Stockholm, London, and Amsterdam, in writing and printing a variety of works in exposition of his experience and doctrines. There is little in any of these which is not comprised in the *Arcana Cœlestia*, and a few notes on its contents may serve as a description of the whole. With many digressions, the *Arcana Cœlestia* is a revelation of the inner sense of Genesis and Exodus. The early chapters of Genesis are a fragment of an older word, preserved at this day in Tartary, and are not historical in a manner-of-fact sense. Adam signifies the most ancient church, and the flood its dissolution; Noah, the ancient church, which falling into idolatry, was superseded by the Jewish. The spiritual sense pervades the Scriptures, with the exception of Ruth, Chronicles, Ezra, Nehemiah, Esther, Job, Proverbs, Ecclesiastes, the Song of Solomon, the Acts of the Apostles, and the Epistles. No fault is found with these books, but inasmuch as they do not possess the internal sense, they are not the word. The Scriptures are read in heaven in the spiritual sense, but as that sense treats exclusively of God and the human mind, it is void of every reference to earthly scenes, persons, and events. By reason of its symbolism of the inward sense, the letter of Scripture is holy in every jot and tittle, and has been preserved in immaculate perfection since the hour of its divine dictation. The Jewish dispensation having reached its period, God appeared in Jesus Christ. He assumed human nature in its basest condition in the Virgin, wrought it into conformity with himself, "glorified and made it divine." The effluence from the redeemed humanity is the Holy Spirit. In a sense the reverse of Socinian, Swedenborg was a Unitarian. He saw God in the Savior, and regarded him as the sole object of worship. The church initiated by the divine advent came to an end in last century, and Swedenborg witnessed the last judgment effected in the year 1757 in the world of spirits. Then commenced a new dispensation, signified by the New Jerusalem in the Revelation, of which Swedenborg was the precursor, and his writings the doctrine. To the objection, that the doctrine is strange and novel, he replied, that mankind were not prepared for its reception, and that the early Christians were too simple to understand it.

One of the chief ends of his mission was the revival of the lost science of correspondences—the science of sciences in the most ancient times. The law of correspondence is universal; the natural world is the outbirth of the spiritual world, and the spiritual world of the invisible mental world. Unseen evil is manifested in things hurtful and ugly; unseen good, in things useful and beautiful. Man is a summary of nature; nature is man in diffusion; all things, therefore, in nature, in fire, air, earth, and water—every beast, bird, fish, insect, and reptile—every tree, herb, fruit, and flower, represent and express unseen things in the mind of man. The Scriptures are written according to correspondences, and by aid of the science their mysteries are unlocked. By it, too, the constitution of heaven and hell is revealed. There are three heavens, consisting of three orders of angels; the first distinguished for love, the second for wisdom, and the last for obedience. All angels have lived on earth; none was created such. They are men and women in every respect; they marry, and live in societies in cities and countries just as in the world, but in happiness and glory ineffable. All in whom love to

God and man is the ruling principle, go to heaven at death. Between heaven and hell, a perfect equilibrium is maintained. As there are three heavens, there are three hells, and every angelic society has an infernal opposite. Hell, as a whole, is called the devil and Satan; there is no individual bearing that name. All in whom self-love is the ruling motive, go to hell. There is no resurrection of the earthly body. Every one passes to his final lot at death, some making a short sojourn in an intermediate state, designated the world of spirits, where the good are cured of their superficial infirmities and intellectual mistakes, and where the evil are stripped of all their pretenses to good.

Swedenborg professed to enjoy a numerous acquaintance with departed celebrities, and some of his verdicts on character are appalling; for example, he describes king David and St. Paul as among the lost, while Louis XIV. and George II. are distinguished angels. Nor did he confine his intercourse to ghosts from earth, but extended it to souls from the moon and planets, with the unfortunate exceptions of Uranus, Neptune, and the Asteroids. For these visions, enjoyed while sitting in his chamber, he had this explanation: although in the spiritual world there are *appearances* of space, there is nothing of the objective reality which here divides London from Melbourne. If one spirit desires to see another, the desire instantly brings them together. A good man is, as to his mind, in heaven, and an evil man in hell; and supposing the spiritual sight of either was opened—that is, if the eyes of the spiritual body, which transfuse and animate the material ones, were disengaged from their fleshly vesture—he would see his spiritual companions and the country where he would abide after death.

The grand and distinctive principle of Swedenborgian theology, next to the doctrine of the divine humanity, is the doctrine of life. God alone lives. Creation is dead—man is dead; and their apparent life is the divine presence. God is everywhere the same. It fallaciously appears as if he were different in one man and in another. The difference is in the recipients; by one he is not received in the same degree as another. A man more adequately manifests God than a tree; that is the only distinction. The life of devils is God's presence perverted in disorderly forms. "All things, and each of them to the very uttermost, exist and subsist instantly from God. If the connection of anything with him were broken for a moment, it would instantly vanish; for existence is perpetual subsistence, and preservation perpetual creation." By this law of life is explained man's self-consciousness, freedom, and personality. All these sensations are communicated from God to man. He dwells in man so cordially that he gives him to feel that he lives of himself, even as he lives.

Swedenborg made no attempt to establish a sect. When he proclaimed the Christian church at an end his expectation was, that a new church would be raised up among the Gentiles; but toward the close of his life he was silent as to that hope, and spent his energies in attacking Protestant theology, as if bent on the conversion of northern Europe. All his works were written in Latin, and received little attention from his contemporaries. Apart from his visions, there was nothing peculiar about Swedenborg. He was shrewd in worldly affairs, affable in society, and discussed politics and finance in the Swedish diet like a man of the world. He was never married. In diet he was a vegetarian.

Swedenborgians, or, as they designate themselves, "The New Church signified by the New Jerusalem in the Revelation," were first organized as a separate body in 1788 by Robert Hindmarsh, a printer in Clerkenwell, London, who was elected by lot to baptize and to ordain his comrades in the ministry. The Swedenborgians accept Swedenborg's voluminous theological writings as nothing less than revelations from heaven. The body has not had a prosperous existence. The number of its registered members in Britain is little over 6300, divided into 81 congregations. These are chiefly in the large towns and in Lancashire; four are in Scotland, but none in Ireland. At one time there were reputed to be a number of receivers of the doctrines of Swedenborg among the clergy of the church of England. The translator of the *Arcana Cœlestia* was the Rev. John Clowes, rector of St. John's, Manchester, for sixty-two years. He died in 1831, and in the pulpit and numerous publications made no secret of his faith. In the United States the Swedenborgians have nearly 100 societies, and about 6,000 members. They chiefly exist in the northern states; and their largest congregation is in Boston. In France, Germany, Sweden, and Russia, there are Swedenborgians, but few and scattered. There is a Swedenborg society, established in 1810, for printing and publishing Swedenborg's works, with a house in London, and an income of about £200 a year. by Prof. Tafel (ed. 1875). See Life by White (1867) and *Documents* published.

SWEDENBORGIANs organized their first congregation in the United States at Baltimore, 1792; and their general convention in 1817, incorporated under the law of Illinois, and having associations, societies, or members, in nearly all the states. It holds annual sessions in different cities, has a publishing house in New York, a theological school at Waltham, Mass., a Sunday-school union and church music society. Much freedom in regard to ecclesiastical forms is allowed, the power to adopt them being lodged in the whole body of members. The form generally preferred in this country is a modified episcopacy; each state association having its overseer, whose office is permanent. In most of the congregations the worship is partly liturgical, and several

books of prayer have been issued; yet as each congregation is free to adopt its own mode, in some only extemporaneous prayers are offered. There is a congregational union, composed of ministers and churches preferring that order, having its headquarters in Philadelphia, with its own board of publication. There are also independent societies and churches not associated together. And, while the number of those who, in an open profession of Swedenborgian doctrines, have separated from other Christian churches is not large, they believe that in all other denominations many persons have adopted more or less of Swedenborg's views. And it is their avowed and cherished purpose to enlarge this number everywhere. A large sum of money has been devoted to publishing some of the most popular of Swedenborg's books for gratuitous distribution to all who apply for them. As reported in the year 1894-5 there were 102 societies, having about 6075 members.

SWEDISH LANGUAGE AND LITERATURE. See SCANDINAVIAN LANGUAGE AND LITERATURE.

SWEDISH MOVEMENT CURE. See MOVEMENT CURE.

SWEEPS, on shipboard, are oars of great length used in large vessels during a calm, to enable the ship to obtain steerage-way.

SWEETBREAD, the pancreas (q.v.) of an animal, used as food; it is highly esteemed as being both delicate and nutritious.

SWEET-BRIER. See ROSE.

SWEET FLAG. See ACORUS.

SWEET GUM. See LIQUIDAMBAR.

SWEETMEAT, a general term applied to such articles of food as consist chiefly of sugar.

SWEET PEA. See LATHYRUS.

SWEET POTATO. See BATATAS.

SWEETS, a term applied in England, and by the board of inland revenue, to home-made wines, for the sale of which a special license is granted. It is also a term in far more general use for lozenges, comfits, and other preparations of sugar well known to children; they are the *confitures* of the French.

SWEETSER, CHARLES HUMPHREYS, 1841-71; b. Mass.; graduated at Amherst, 1862; entered literary life, and was one of the founders of the *Round Table*, and of the *Evening Mail*, with which he was connected until 1869. He wrote a history of Amherst college, a collection of college songs, and an *Invalid's Guide to the North-west*.

SWEETSER, SETH, D.D., 1807-78; b. Newburyport, Mass.; d. Worcester, Mass.; graduated at Harvard coll., and at the Andover Theol. sem. He was called to the Central Cong. church, Worcester, Mass., 1838, and remained in that pastorate until his death. He was held in high esteem for practical wisdom and theological learning.

SWEET SOP, *Anona squamosa*, a fruit of the same genus with the custard apple (q.v.). It is produced by a small bush, with lanceolate leaves, a native of the warm parts of America, and much cultivated in Brazil, the West Indies, and generally in tropical countries. The fruit is greenish, and resembles an artichoke in size, in form, and in its scaly covering. The pulp is soft, somewhat mealy, sweet, and luscious; with a musky aromatic odor and flavor. It is much used both in the East and West Indies, generally raw, but sometimes cooked. Notwithstanding its foreign origin, it has proved the staff of life to the people of Hindustan in seasons of famine. The seeds are acrid, and the powder of them is used to destroy insect vermin.

SWEETWATER, a co. in s.w. Wyoming, having for its s. boundary parts of Carbon co. and of Utah and Colorado, for its n. boundary Fremont co., and for its w. boundary Vinta co.; area, 10,230 sq. m.; pop. '90, 4941. It is drained by the Green and Big Sandy rivers, and Packers, Sulphur, Bitter, and South Bitter creeks; is nearly bisected by the Wind river range of the Rocky mountains; and is crossed by the Union Pacific railroad. It was set off principally from Fremont co., containing several noted mountain peaks and passes, in 1884. The principal industries are mining and stock-raising. Co. seat, Green River.

SWEET CORN. See CORN.

SWEET WILLIAM. See PINK.

SWEET WOOD. See CASCARILLA.

SWELL, in music, a set of pipes in an organ with a separate keyboard, and forming a separate department, which are capable of being increased or diminished in intensity of sound by the action of a pedal on a series of shades or shutters overlapping each other like Venetian window-blinds, within which the pipes in question are inclosed. On a well-constructed swell, a practiced performer can imitate not only a gradual *crescendo* and *diminuendo*, but also a *sforzando*, a very small opening suffering to make an immediate burst on the ear; while, when the shutters are closed, an imitation of an echo is produced.

SWETCHINE, or **SVETCHIN**, ANNE SOPHIE, 1782-1857; b. Moscow; the daughter of Soimonoff, who was one of the founders of the Academy of Sciences at Moscow. She was brought up at the court of Catherine II., and in 1799 married Gen. Swetchine. She gathered round her Russians and French emigrants of distinction, and her *salon* at St. Petersburg became very celebrated. In 1815 she was converted to Roman Catholicism, and then removed to Paris. After her death, her literary executor, De Falloux published *Mme. Swetchine, sa vie et ses œuvres* (1859); her *Lettres* (1862); *Journal de sa Conversion* (1863); and *Lettres Inédites* (1866).

SWETT, SAMUEL, 1782-1866, American author; b. Newburyport, Mass.; graduated at Harvard college, 1800, and served on the northern frontier during the war of 1812. He wrote a *Sketch of the Bunker Hill Battle* (1818); *Defence of Timothy Pickering against Bancroft's History* (1859); *The Original Planning and Constructing of Bunker Hill Monument*, and a number of other works, including fugitive poems.

SWIETEN, GERARD VAN, 1700-72; b. Leyden, Holland; educated in his native place, and at Louvain; studied medicine at Leyden with Boerhaave, who obtained him the professorship of medicine in 1725. He was a Roman Catholic, and obliged for that reason to resign his chair. He was first physician to Maria Theresa of Austria, 1745, who made him a baron of the empire. By his influence the university was rebuilt, and a system of clinical instruction established at Vienna. He was opposed to the practice of vaccination. For 8 years he lectured on Boerhaave's *Institutes*, and adapted his system to that of his master; content to engraft the result of his own experience upon it instead of founding a school of his own. Besides his comments on Boerhaave, he wrote treatises on the diseases of armies and on epidemics. A statue to his memory was placed in the university by Maria Theresa.

SWIETENIA. See MAHOGANY.

SWIFT, *Cypselus*, a genus of birds of the swallow family. The distinctive characters of the group, of which the true swifts are the type, are noticed in the article SWALLOW. The swifts, like the swallows, are widely distributed, and some are only found in tropical countries; others are birds of passage, and spend the summer in colder parts of the world. Many of the swift group are often popularly called swallows, as that which produces the edible nests of the East Indies. In the genus *Cypselus*, as now restricted, the tail is generally forked, the legs and toes feathered, and very small and weak, all the four toes directed forward. The birds of this genus pass most of their time in the air, and even copulate on the wing. The wings are longer than in any other bird; and the internal structure, even of the skeleton, is peculiarly adapted to prolonged flight. The anatomy more resembles that of humming-birds than of true swallows.—The COMMON SWIFT (*C. apus*) is common in almost all parts of the n. of Europe and of Asia in summer, retiring to tropical or subtropical regions in winter. It occurs even in Lapland. Its residence in its summer quarters is much shorter than that of swallows; and it is worthy of notice, that the swift is seldom to be seen along with any of the swallows or martins, the different kinds choosing different localities, even although very close together. The swift is easily recognized in its flight by the remarkably sickle-shaped wings, and its slight scream is very different from the twitter of the swallow. It is black, with a white throat. It makes its nest in holes of rocks or of walls, often in those of houses. The nest is formed of bits of straw, dry blades of grass, and bents, feathers, and other such substances, which are apparently glued together by a mucous secretion. The swift sometimes builds in hollow trees. Swifts, like swallows, seem to return to the same place to make their nest, year after year, and repair the old nest, instead of making a new one.—The ALPINE SWIFT, or WHITE-BELLIED SWIFT (*C. alpinus*), is rarely seen in Britain, but is common in the more southern countries of Europe. It builds in high rocks, sometimes in steeples. It is larger than the common swift, and is the largest of the British *Hirundinidae*. Its wings are even longer in proportion than those of the common swift. Its voice is sweet, not a scream like that of the common swift.—The AMERICAN SWIFT (*Chaturapelasgia*) has the hind-toe directed backward, and the tail feathers stiff and pointed, as in woodpeckers. It is a small bird, not above 4½ in. in entire length, but 1 ft. in extent of wing. The general color is brownish black, with greenish reflections, the throat grayish white, the under parts grayish brown. The nest is made of small dry twigs, which the bird breaks off from the tree, and carries away in its feet; and they are attached by means of the saliva, to the rock, wall, or hollow tree where the nest is made. From its frequently building in chimneys, this species is known as the *Chimney Swallow* in North America. Great numbers often build together. See illus., LARKS, ETC., Vol. VIII.

SWIFT, a co. in w. Minnesota, drained by the Minnesota, Chippewa, and Pomme de Terre rivers; intersected by the Great Northern railroad; about 653 sq. m.; pop. '90, 10,161, chiefly of American birth. The surface is mostly level, with little timber. The soil is extremely fertile. The principal production is wheat. Co. seat, Benson.

SWIFT, JONATHAN, the greatest of English satirists, and the most original writer of his age, was born in Dublin, but of English parents, on Nov. 30, 1667. He was a pos-

thumous child, reared amid circumstances of abject poverty and dependence, the recollection of which galled his proud irascible spirit, and embittered much of his future existence. He was supported by relatives, and educated at Kilkenny school and Trinity college, Dublin. He proved a negligent and turbulent student, more intent on personal satires and political rhymes than academical honors: but he remained at college about seven years. He then removed to England, visited his mother in Leicestershire, and by her recommendation was admitted into the house of sir William Temple, who had long known the Swift family. He seems at first not to have conciliated the regard of the retired minister, for in the following year (May, 1690), Temple made an offer of the services of his protégé to sir Robert Southwell (then about to proceed to Ireland as secretary of state), recommending him as diligent and honest, qualified either to wait on sir Robert as a gentleman, or to write under him as a clerk. No appointment followed; Swift remained with Temple, studying hard, till 1694, when he went to Ireland, took orders in the church, and obtained a small living, which he threw up in two years, and returned to England, in consequence of Temple, who missed his society and assistance, urging him to come back. Temple died in 1698, and Swift in the following year, published his posthumous works, after which he again repaired to Ireland, obtaining from lord Berkeley some church preferments, including the vicarage of Laracor, worth in all about £400 per annum, which was all the professional income he enjoyed till he was appointed dean of St. Patrick's, in his 46th year. Before this, he had written the wildest and wittiest and most powerful satirical work of the 18th c., *The Tale of a Tub* (1704), also a few essays on ecclesiastical subjects, some inimitable ridicule of astrology under the name of Isaac Bickerstaff, and poetical pieces possessing a peculiar vein of humor and description. In 1710 he went over to the Tories, conceiving himself neglected by the Whig ministers, and exerted himself strenuously in behalf of his new allies, Harley and Bolingbroke. He wrote papers in *The Examiner* (1710); a *Letter to the October Club* (1711); *The Conduct of the Allies* (1712); *The Barrier Treaty* (1712), and innumerable pasquinades against the Whigs, whom he "libelled all round." He had become, as it were, a great and formidable power in the state, yet could extort no higher preferment for himself than the deanery of St. Patrick's. His party was overthrown by the death of queen Anne; and in 1714 Swift "commenced Irishman for life," with strong reluctance and disgust. In time, however, he took interest in Irish affairs, and identified himself with Irish feelings and prejudices. Hatred to Walpole and the English government quickened his activity; and his resistance to Wood's copper coinage—a scheme for supplying Ireland with copper money by an English patentee—raised him to the highest pinnacle of popular favor. His *Drapier Letters* (1724) produced quite a ferment in Ireland, and compelled the government to abandon the scheme of the coinage. Two rewards of £300 each had been offered for the unmasking of the Drapier, but not a traitor, as he says, could be found to sell him. The triumphant author made his last visit to England in 1726, and published his *Gulliver's Travels*, the most universally popular of all his works. He next joined with Pope, Arbuthnot, and Gay in publishing three volumes of *Miscellanies*, after which he returned to Ireland (Oct., 1727), and never left it again. He was subject to fits of giddiness and deafness, which increased in frequency and intensity as he grew old; he brooded over the anticipated madness which he foreboded would be his future lot; his temper, always irritable and gloomy, became more violent and morose, the effect of cerebral disease, and his memory and other faculties gave way. There was also a deep and secret grief: the fate of two ladies, known as Stella and Vanessa, had been inseparably entwined with his own destiny; both had sacrificed for him all but honor, and had sunk under disappointed hopes and blighted affection. We cannot here trace the painful story, which is still involved in mystery, but for a time the retribution of Swift was terrible. He rallied, however, and wrote some of his best minor pieces after this period. Among these are *The Grand Question Debated*; *On Poetry, a Rhapsody*; *The Legion Club*; *Verses on the Death of Dr. Swift*; and that extraordinary prose tract, *The Modest Proposal*, a masterpiece of irony, in which he proposes to relieve the distresses of the poor Irish by converting their children into food for the rich. The last three years of Swift's life were passed in almost total silence in the hands of keepers. He died Oct. 19, 1745.

It would be superfluous to attempt in our brief space to characterize the genius of the immortal dean of St. Patrick's. Shakespeare alone among English authors has received a greater amount of criticism and annotation. From Johnson to Thackeray, the most brilliant critics and biographers have employed themselves in elucidating his strange and sad history, and in estimating his writings. As a consummate master of ridicule and irony, possessing great powers of wit, invention, illustration, and analogy; possessing also the dramatic faculty that enabled him to assume and portray varieties of character; and as writing a pure, perspicuous English style, unsurpassed for strength and simplicity, Swift must ever be a model in our language and literature. His misanthropy, or degradation of human nature—his Yahoos, Strulbrugs, daring irreverence, and indelicacy, are of course indefensible. He had a total incapacity, as De Quincey remarks, for "dealing with the grandeurs of the human spirit, with religion, with poetry, or even with science, when it rose above the mercenary practical." His business was with the

world—with the follies, vices, and absurdities of men. And his poetry is the same as his prose; it may come under his definition of a good style, "proper words in proper places," applied to ordinary topics, but is wholly wanting in passion, elevated feeling, and imagination. A complete edition of his works, in 19 vols., was published by sir W. Scott (1815). See also Roscoe's edition (1853), and *Life* (unfinished), by John Forster (1875).

SWIFT, JOSEPH GARDNER, LL.D., 1783–1865; b. Mass.; in 1802 graduated at West Point, the first graduate from the academy. He was commissioned in the engineers, rose to be chief of the corps with rank of colonel, and in the war of 1812 served on Pinckney's staff and later had charge of the defenses of New York. In 1815 he was superintendent and inspector of West Point; resigned in 1818, and became surveyor of the port of New York. From 1829 to 1845 he was engaged in the harbor improvement of the great lakes, and in this period superintended the construction of the New Orleans and lake Pontchartrain railroad, a work of great difficulty on account of the swamps. In 1833 he was chief engineer of the New York and Harlem railroad.

SWIFT, LEWIS, b. at Clarkson, Monroe co., N. Y., 1820. He early became a lecturer and experimenter in physics, but after 1855 gave his chief attention to the study of comets and to general astronomy. His discoveries and observations, made as director of the Warner observatory at Rochester, N. Y., won for him honorable recognition in America and Europe.

SWIFT, WILLIAM H., b. Mass., 1800; educated at West Point. He joined Long's Rocky mountain expedition in 1818, and was on topographical duty, 1821–32, making surveys on the Chesapeake and Ohio canal, the Florida canal, and several railroads. For the ten years from 1832 he was attached to the geodetic survey of the Atlantic coast, supervising the river and harbor improvements, 1837–42. He was also constructing engineer of the Western railroad in Massachusetts, 1836–40. He supervised the construction of the Minot's Ledge light-house, 1847–49. Resigning from the army in 1849, he became president of the Philadelphia, Wilmington and Baltimore railroad, and afterward of the Western railroad, and the Illinois and Michigan canal. He d. 1879.

SWILLY, LOUGH, an inlet of the Atlantic on the n. coast of Ireland, in the county of Donegal, enters between Dunaff head on the e., and Fanad point, on which there is a light-house, on the west. Length 25 m.

SWINBURNE, ALGERNON CHARLES, one of the first of living English poets, is the son of Admiral Charles Henry Swinburne, by lady Jane Henrietta, daughter of the third earl of Ashburnham, and was born in London on April 5, 1837. He entered as a commoner at Balliol college, Oxford, in 1857, but left the university without graduating. His first literary venture, a volume published in 1861, containing two plays, *The Queen Mother and Rosamund*, attracted little attention; but *Atalanta in Calydon*, a tragedy, which appeared in 1865, at once established his reputation. Afterward came *Chastelard*, a tragedy (1865); *Poems and Ballads* (1866); *A Song of Italy* (1867); *Siena* (1868); *Songs before Sunrise* (1871); *Bothwell*, a tragedy (1874); *Erechtheus* (1875); a new series of *Poems and Ballads* in 1878; *Songs of the Springtides* (1880); *Mary Stuart, a Tragedy* (1881), which, taken in connection with *Chastelard* and *Bothwell*, completes a dramatic trilogy; *Tristram of Lyonesse*, and *Other Poems* (1882); *A Century of Roundels* (1883); *A Midsummer Holiday* (1884); *Marino Faliero, a Tragedy* (1885); and *The Armada* (1888); *Astrophel and other Poems* (1894); *The Tale of Balen* (1896). As a poet he can hardly be said to have fulfilled the promise of his youth. His passion and vehemence and extraordinary command over unsuspected sources of melody caught the public ear almost from the first, and made men believe that a great new lyric poet had arisen. But in the judgment of many critics he has little power of sustained thought or imagery; he is ever ready to sacrifice sense to sound; his poetry is mere music, and the music is always set to the same tune. Swinburne belongs to what has been aptly called the "fleshy school" of poetry, and even those who most admire his power of poetical expression, richness of coloring, and happy lyrical effects must deplore the sensuous tone of his muse. He has also been severely animadverted upon for the wanton violence with which he attacks the most sacred beliefs of his fellow-men. Swinburne is well known in the department of poetical criticism. His prose, much of which is admirable, includes *William Blake, a Critical Essay* (1868); *Essays and Studies* (1875); *Note on Charlotte Brontë* (1877); *A Study of Shakespeare* (1879); *Life of Victor Hugo* (1886); *A Study of Ben Jonson* (1890); *Studies in Prose and Poetry* (1894); besides essays contributed to periodical literature and to the *Encyclopædia Britannica*.

SWINDON, an old market t. of Wilts, 77 m. w. of London by the Great Western railway. It contains a handsome church, large corn exchange, and excellent shops. About a mile n. of the town is Swindon junction, the great central establishment and manufactory of the Great Western railway company. A considerable town has risen around the station, called the New town, and containing a beautiful church, public park, library, and mechanics' institute. Pop. '91, of Old town, 5545; of New town, 27,295.

SWINE. See Hog.

SWINE-OAT. A species of oats (the *avena nuda*) cultivated in some parts of England as food for swine.

SWINE-PLAGUE, or **HOG CHOLERA**, an infectious disease produced by a bacteroid schizophyte, a microscopic organism having the power of indefinite multiplication in the system. The symptoms and pathological conditions vary considerably, depending upon the virulence of the disease, this depending very greatly upon the number of animals kept together, crowding greatly aggravating the disease. At the commencement of the attack the animal is generally seized with a shivering, which may last from a few minutes to several hours. There is also frequent sneezing and more or less coughing. The temperature of the body is also increased, ranging from 104° to 106° Fahr. but this symptom is variable, and not to be relied upon; and it is difficult to ascertain the temperature of a hog. The shivering, coughing, and sneezing are soon followed by loss of appetite and the rough appearance of the coat. Drooping of the ears is characteristic, and sometimes the animal attempts to vomit. Swelling of the head often takes place, and eruptions appear on the ears and other parts of the body. There is frequently bleeding from the nose, swelling of the eyelids and partial or total blindness, accelerated breathing; sometimes constipation, and sometimes diarrhea. There is rapid emaciation, and a vitiated appetite for dung and dirt, and a peculiar, offensive odor to the exhalations which is characteristic. This odor is so penetrating as to be observed in a large herd at the distance of half a mile. On examining the chest by auscultation a rubbing sound is heard which indicates inflammation of the pleural membrane. Sometimes there is extensive ulceration and sloughing of the snout and gums. If the subjects have been recently ringed with wire in the nose, the wounds thus made have a great tendency to ulcerate, and the disease may be communicated through wounds or abrasions of any kind. Post-mortem examinations reveal more or less hepatization of the lungs, with accumulation of blood, serum, and exudation in the lung tissue. Sometimes the solidification from hepatization is sufficient to cause the lung to sink in water. Sometimes the hepatization occurs only in isolated places, but sometimes extends over the whole lung. Gray and red hepatization may exist side by side. The lymphatic and mesenteric glands are always more or less enlarged. There is generally more or less exudation of plastic material, and more or less adhesion between the lung and the walls of the chest. Sometimes the adhesion involves the whole lung. The heart is generally more or less affected. Sometimes it is flabby and dilated, but more frequently congested, the capillaries, particularly of the auricles, being gorged with blood. Nearly all cases present characteristic morbid changes in the upper part of the large intestine, consisting of ulcerous tumors of the mucous membrane, varying in size from a pin's head to that of a quarter of a dollar. The other intestines are similarly affected, although in a less degree. Ulcerous tumors are also sometimes found upon the gall bladder and upon the mucous membrane of the stomach. The serous membrane of the abdominal cavity is also inflamed, so that there will be adhesions between different parts of the intestines, or between them and the peritoneal lining of the abdominal walls. Indeed, in the worst cases, it may be said that scarcely an organ escapes sufficiently not to exhibit lesions visible to the naked eye. A microscopic examination of the blood, or blood serum, or exudations, reveals great numbers of schizophytes in various stages of formation, some in separate minute globules, of micrococcus stage, some in aggregated masses, and some in bacillus rods. The disease is communicable to other animals by inoculation, and rats may contract it and cause it to spread. Dogs appear to have but little susceptibility, but do sometimes contract the disease. The extreme cold of winter checks the spread of the complaint, but the disease germs, or schizophytes, are not killed by it, although the thermometer may mark 30° below zero. The above information is chiefly taken from the reports of Dr. H. J. Detmers of Chicago to the governmental agricultural bureau at Washington; and the following is from a paper read before the state microscopical society of Illinois, April 8, and published in *Science* of May 7, 1881: "1. It has been and can be everywhere observed, where swine-plague is prevailing, that the infectious principle floating in the air is attracted and taken up by sores, wounds, and even scratches, but does not enter the animal organism through the whole skin and through perfectly healthy respiratory mucous membranes. 2. Antiseptics, or medicines which are either directly poisonous to the lower forms of organic life or destructive to those conditions under which low forms of organic life thrive and develop, and among those antiseptics, especially carbolic acid, iodine, hyposulphite of soda, benzoate of soda, thymol, etc., have proved to constitute almost sure prophylactics. . . . Further, the various antiseptics which have proved to be good prophylactics are very dissimilar in their chemical affinities and actions, and their prophylactic effect cannot very well be explained if the infectious principle were a chemical agency, a virus, or a poison, but is explained if the same consist in something endowed with life and power of propagation. . . . 6. If the causé and infectious principle of the swine-plague were a chemical poison or virus, one would suppose a cessation of the morbid process would be impossible, and an animal would never recover while its organism contained an abundance of the infectious principle in an effective condition, as is undoubtedly the case, because convalescents and animals nearly recovered frequently communicate the disease, even in a fatal form, to other healthy pigs. Further,

the fact that an animal, once recovered, possesses but little predisposition for future infection, or is seldom attacked a second time, even if ever so much exposed, and then only contracts the disease in a comparatively mild form, could never be explained; but the whole presents an entirely different aspect, and admits of explanation if low and minute forms of organic life, such as the schizophytes of swine-plague, which by developing and multiplying finally destroy or exhaust in an animal organism the conditions necessary to future development and propagation, constitute the cause and the infectious principle." Dr. Detmers says that the swine-plague schizophytes, although having the same general characteristics when cultivated in fluids artificially as when developed in the animal, have less uniformity in size and develop rather slower. He concludes that they are less vigorous; and therefore when an animal is inoculated with them the disease produced is milder than when propagated in the ordinary manner, or by material taken from the body of a diseased hog. Sometimes, however, owing to other circumstances, inoculation with cultivated schizophytes produces a virulent form of the disease. In regard to prevention, Dr. Detmers, in his report to the commissioner of agriculture, July, 1879, takes the ground that measures of extermination must be thorough. He advises: 1, "that a competent and reliable person be appointed in every county, or where a great many hogs are raised, and where the country is thickly settled, in every township, with authority to institute, superintend, and enforce a strict execution of such measures of extinction and prevention as may be authorized by law; 2, that every owner of hogs or pigs must be compelled by law to inform the above officer, say within 12 hours after the occurrence, of every case of swine-plague in his herd, or any herd, that may come to his knowledge; 3, that every hog or pig showing symptoms of swine-plague must be immediately destroyed and buried from 4 to 6 ft. deep, or cremated, and that all exposed hogs be kept under quarantine for several weeks or killed; 4, that all infected premises be thoroughly cleaned and disinfected, and remain unoccupied for six weeks or two months; 5, that no hog or pig be allowed to run at large or to have access to running water if swine-plague has made its appearance within 10 m.; 6, that railroad companies and other public carriers be forbidden to receive and load hogs from any township or county after having been notified by the proper officer that swine-plague is there existing, except by special permit of such officer, and various other restrictions. The treatment most relied on is good care, uncontaminated and pure food and water, perfect cleanliness, and separation from sick animals and all other sources of infection."

SWINEMÜNDE, a maritime and fortified t. of Prussia, province of Pomerania, is situated on the island of Usedom, at the entrance of the narrow channel of Swine, which connects the Grosses Haff (into which the Oder flows) with the Baltic. Swinemünde, as in some sense the port of Stettin (q.v.), carries on a considerable commerce, and has also valuable fisheries, but it is chiefly noted for its excellent sea-bathing, for which it is much frequented. The lighthouse of S. is 210 ft. high. Pop. '95, 9391.

SWING, DAVID, D.D., b. Cincinnati, 1830; educated at the Miami Univ., Oxford, O.; was principal of the Oxford Grammar School for 12 years. He became pastor of a Pres. church in Chicago, where his original style of thought and his bold though modest utterance commanded public attention, and excited the criticism of those who prized the form of sound words established by ecclesiastical authority. In the interest of peace Dr. S. retired from his pastorate and from the Pres. ministry; his supporters went with him to a public hall, where he has since preached to one of the largest congregations in Chicago. His preaching, though diverging from the verbal standards of "orthodoxy," was essentially evangelical and spiritual, as well as marked by intellectual power. Prof. Swing published *Truth for To-Day*, *Motives of Life*, *Sermons*, and *Club Essays*, and was a frequent contributor to magazines and newspapers. He died in 1894.

SWINTON, JOHN, b. Scotland, 1830; educated at East Hampton, Mass. He was at one time chief of the editorial staff of the *New York Times*, and held a similar position on the *New York Sun*; editor of *John Swinton's Paper*, since 1883. Among his writings are *European Travels*, *The Chinese Question*, and *Life of John Brown*. He is active as a propagandist of "the principles of equal rights for all men."

SWINTON, WILLIAM, b. Edinburgh, 1833; removed to the United States when ten years old, and pursued his studies at Amherst College. In 1853 he was a teacher in a female academy in Goldsborough, N. C.; but soon after settled in New York; where he devoted himself to study, and to making translations from the French, the most important being that of Rousseau's *Confessions*. On the outbreak of the civil war he was sent to the front as war-correspondent for the *New York Times*, and served principally with the army of the Potomac, of whose career he was afterward a historian. Soon after the war he was appointed professor of *belles-lettres* in the university of California at Oakland. Later in life he devoted himself to writing educational works. Swinton published *Rambles among Words*; *Campaigns of the Army of the Potomac*; *The Twelve Decisive Battles of the War*; and geographies, grammars, and reading-books. D. 1892.

SWISHER, a co. in n.w. Texas; formed 1876; organized 1890. Area, 900 sq. m. Pop. '90, 100. Co. seat, Tulia.

SWISS GUARDS, first employed in the French service in 1616. It was the policy of the royal family to render these guards personally faithful to themselves, and to estrange them from the other soldiers and the common people. How well they succeeded was shown by the slaughter of 1792 at the Tuileries. The *Lion of Lucerne*, erected in 1821, commemorates their valor. The Swiss guard also existed in France under Louis XVIII., and up to 1830. A body of Swiss guards have long acted as the pope's guard at the Vatican.

SWISSELM, JANE GRAY CANNON, b. Wilksburg, Penn., 1815; editor of the *Pittsburg Saturday Visitor*, 1845-56; of the *St. Cloud (Minn.) Visitor*, 1858; and of the *St. Cloud Democrat*, 1858. She was also a contributor to *Neal's Gazette*, *The Dollar Newspaper*, *The Spirit of Liberty*, *The Commercial Journal*, *New York Tribune*, etc.; and pub. *Letters to Country Girls* and *My First Holiday*. She dealt forcibly with political and social life in the interest of reform. She d. 1884.

SWITHIN, SAINT, an English ecclesiastic of the 9th c., who was chaplain to king Egbert, and tutor to his son Ethelwulf, under whom, when he came to the throne, he held the office of chancellor. He had the charge of the education of king Alfred, whom he accompanied to Rome. In 852 he was consecrated bishop of Winchester. According to William of Malmesbury, he was "a rich treasure of all virtues, and those in which he took most delight were humility and charity to the poor." He adds that he built several churches, and traveled through his diocese with his clergy on foot, and for the most part by night, in order to avoid the appearance of ostentation. The origin of the tribute called "Peter-pence" (q.v.) has been often assigned to Swithin, and he is said to have procured an act of the Wittenagemote, enforcing, for the first time, the universal obligation of paying tithes. Swithin died on July 2, 862, and was buried, according to his own desire, in the churchyard of Winchester. A century later he was canonized; and the monks, not considering this a fitting place of sepulture for a saint, exhumed his body, for the purpose of depositing it in Winchester cathedral; but this translation, which was to have taken place on July 15, was delayed in consequence of violent rains, which continued without intermission for 40 days. Out of this circumstance arose the still current belief, that if rain fall on July 15, it will continue to rain for 40 days. Experience certainly shows that when a period of wet weather sets in about the summer solstice, it generally proves of considerable duration; and we find a similar superstition popularly attached in different countries of Europe to the festivals of various saints, which occur about the same period of the year. In France, the watery saints' days are those of St. Médard (June 8), and St. Gervais and St. Protas (June 19), the meteorological canon being—

S'il pleut le jour de Saint Médard,
Il pleut quarante jours plus tard;
S'il pleut le jour de St. Gervais et de St. Protas,
Il pleut quarante jours après.

The rainy saint in Flanders is St. Godeliève, and in Germany there are three saints' days to which this belief attaches, one being that of the Seven Sleepers.

SWITZERLAND (Ger. *Schweiz*; Fr. *Suisse*; It. *Svizzera*) is an inland country of Europe, situated between 45° 48' to 47° 49' n. lat., and 5° 55' to 10° 30' e. long. Its greatest length from e. to w. is 180 m., and its greatest width from n. to s., 130 miles. Its superficial area, without including lakes, is 15,233 sq.m., or one-fourth of that of England and Wales. In 1888 the pop. of Switzerland was 2,918,179; in 1894 according to estimates, 2,986,848. The following table from the *Statesman's Year Book* for 1897 gives the results of the census of 1888 and the estimates for 1894.

| CANTONS. | Area in Eng. Sq. Miles. | Population, 1888. | Population, June, 1894. |
|----------------------------|----------------------------|----------------------|----------------------------|
| Zürich | 666 | 337,183 | 351,917 |
| Bern | 2,657 | 536,679 | 541,051 |
| Lucerne | 579 | 135,360 | 135,813 |
| Uri | 415 | 17,249 | 17,249 |
| Schwyz | 351 | 50,307 | 50,581 |
| Unterwalden | 295 | 27,581 | 27,781 |
| Glarus | 267 | 33,825 | 33,535 |
| Zug | 92 | 23,029 | 23,167 |
| Freiburg | 644 | 119,155 | 122,058 |
| Soleure | 302 | 85,621 | 89,290 |
| Basel | 177 | 135,690 | 144,283 |
| Schaffhausen | 114 | 37,783 | 37,465 |
| Appenzell (exterior) | 162 | 66,997 | 68,515 |
| St. Gall | 779 | 228,174 | 241,055 |
| Grisons | 2,773 | 94,810 | 95,469 |

| Tessin, or Ticino | 1,088 | 126,751 | 127,940 |
| Vaud | 1,244 | 247,655 | 256,242 |
| Valais | 2,027 | 101,985 | 103,236 |
| Neuchâtel | 312 | 108,153 | 111,928 |
| Geneva | 108 | 105,509 | 109,557 |
| Totals | 15,975 | 2,917,754 | 2,986,758 |

Surface.—Switzerland is the most mountainous country of Europe. Its principal chains are the Alps (q.v.) and the Jura (q.v.). The former run from e. to w. along its southern or Italian frontier. Their ramifications fill more than one-half of the country, and terminate along a line which may be traced from Vevey, on the lake of Geneva, to mount Moleson and mount Napf, across lake Zug, to the southern shores of the lakes of Zürich and Wallenstadt, and Sargans on the Rhine. The mean elevation of the highest chain is from 8,000 to 9,000 feet. The Jura run n.e. from the western corner of Switzerland. They consist of a series of parallel ridges inclosing long and narrow valleys, and their mean elevation does not exceed 4,000 feet. In the angle formed between them and the Alps lies the plain of Switzerland, a table-land 100 m. in length, and from 20 to 30 m. in width, with a mean elevation of about 1400 ft. above the sea. It is not absolutely level, but covered with elevations, which seem very unimportant, however, when contrasted with the huge masses of the Alps and Jura. It has been described, and not inaptly, as a corner of southern Germany, penetrating like a wedge between France and Italy. The communication between the plain of Switzerland and the German valleys of the Danube and Rhine is not, however, continuous. The plain on the e. terminates in a third hilly tract—the Thur hill-country, which lies between the lakes of Zürich and Constance, and which, to some extent at least, forms a barrier between the plain of Switzerland and Germany. The Jura, the plain, and the hill-country are, then, the great divisions of northern Switzerland. The divisions of the Alpine region are more strongly marked in nature. A glance at the map will show that the chains which overspread it radiate from a mountain knot lying to the w. of the Grimsel pass. They isolate and inclose (1) the valleys drained by the Rhone, which connect Switzerland with southern France; (2) Ticino, drained by streams which descend to the Po, and have at all times brought this country into close communication with Italy; (3) The Grisons, the most sequestered valleys of Switzerland, drained by the tributaries of the Rhine and Danube, and shut out by mountains from the lower basins of these rivers; (4) The Bernese Oberland, which slopes toward the western extremity of the Swiss plain; (5) The district of the forest cantons—Schwyz, Uri, and Unterwalden—surrounding the lake of Lucerne, and which slope toward the eastern extremity of the plain, and seem a great mountain fortress erected in the very heart of Switzerland, to protect the plain against German invasion.

Geology is of little importance in explaining the general geography of Switzerland. It may, however, be stated that in the southern Alpine region the rocks are crystalline; that in the northern Alpine region they belong to the jurassic and other upper secondary strata; and that in the plain and the great part of the hill-country they consist of loose tertiary sands and clays, which supply the best agricultural soils of Switzerland. Those rocks and formations in which mines and coal chiefly abound are absent.

Climate.—In Switzerland the climate chiefly varies with elevation above the sea-level. At a height exceeding 9,500 ft., the mountains are covered with perpetual snow, which descends along the hollows in glaciers (q.v.) to a much lower level, and in this way covers the elevated part of the country with a vast sea of ice. Below the level of perpetual snow, the surface of Switzerland has been divided into a series of belts, characterized by different climates and productions. The highest of these, lying between the snow and the level of 6,900 ft., has been called the upper Alpine region. In it the glaciers fill the valleys, but plants clothe the scanty soil of the ridges. The second or lower Alpine belt descends to 4,800 feet. It is a country of pastures, in which shrubs but no trees make their appearance. The Righi Pass, the Grimsel Hospice, and the Splügen are included in it. The third belt descends to 4350 feet. The meadows still abound in it, but forests of firs and maples in many parts replace them. It includes Urfenthal and Oberengadin. The fourth belt sinks to 3,000 feet. The forests still abound, the beech being the prevailing tree. The meadows are excellent, and rye and barley are successfully cultivated. It includes Weissenstein, Grindelwald, and Engelsberg. The fifth belt lies above 1800 feet. In it the oak and walnut are the characteristic forest trees. Spelt and the best wheat are cultivated. It includes Bern, Coire, and St. Gall. The last belt sinks to 750 feet. In it the chestnut is the characteristic tree; the mulberry and the vine are extensively cultivated, and wheat is the grain chiefly grown. This belt includes the greater part of the Swiss plain, and sinks to its lowest level in the valley of the Rhine, between Constance and Basel, and the banks of lake Zürich and the lago Maggiore. In the last district the vegetation is that of northern Italy. At a higher elevation than 6,400 ft., Switzerland is only inhabited by herdsmen during the summer months. At this limit, however, permanent abodes begin to make their appearance; and at 4,000 ft. there are many villages. The most populous part of Switzerland, however, lies between 1250 and 2,150 feet. The temperature of this region is fairly represented by that of Zürich, which we will compare with that of London. The temperature of Zürich is in winter 30.34°; in spring, 47.25°; in summer, 64.15°; in autumn, 49.05°; for the year, 47.95°. The temperature of London is in winter, 38.22°; in spring, 48.34; in summer, 61.74°; in autumn, 50.29°; for the year, 50.50°.

Productions.—In Switzerland, where good coal is not to be had, and where the houses are built of wood, the forests, which cover one-sixth of the whole surface, acquire very great importance. Wood-cutting is one of the chief employments of the people. The trees cut down in the highlands are deprived of their branches, and shot with inconceiv-

able rapidity over the slopes to the valleys below, whence they are removed by rafts, not only to different parts of Switzerland, but to France and Germany. It is, however, the mountain-pastures and the meadows, forming two-fifths of the whole surface of the country, that supply the chief occupations of the people—those of herdsmen and shepherds. During the summer the cattle are driven into the mountains, and tended by herdsmen, who take up their abode in the rude wooden huts known as *châlets*, and there the butter and cheese are made. In summer it is estimated that there are in Switzerland upward of a million of horned cattle, one-fourth of which consists of milch cows. The produce of the dairy annually is valued at between one and two millions sterling. The best breeds of cattle are those of Saanen and Simmenthal in Bern, Gruyères in Freiburg, Schwyz, Zug, Entlebuch, Pralligau in the Grisons, and Glarus. The best cheese is made at Emmen, Saanen, Simmenthal, Gruyères, and Ursern. The sheep of Switzerland are of inferior breed, and their wool is short and coarse; but the goats are numerous and fine. More than two-thirds of Switzerland does not supply corn enough to feed its inhabitants. The plain, however, is a fertile agricultural country. In Vaud and Neuchâtel the cultivation of the vine is the chief occupation of the people; and in the Thur hill-country, more particularly on the shores of the lake of Constance, there are extensive orchards, in which are prepared cider and *kirschwasser*, the latter being a liquor largely consumed in Switzerland. It will give some idea of the extent to which Switzerland is cultivated to state, that out of every 100 sq. m. of surface, 30 are occupied by rocks, glaciers, and water; 20 by hill-pastures; 17 by forests; 11 by arable lands; 20 by meadows; and 1 by vineyards. In the uncultivated part of the country the bear, the wolf, and the larger birds of prey are still met with; and the chamois (q. v.) is hunted. The rivers and lakes abound with fine fish, and more especially with trout.

Manufactures.—The manufacturing districts are not scattered over the whole surface of the country, but are met with chiefly on the northern frontier. The largest number of employees are engaged in the cotton industry. Next in importance are the manufacture of silk, watch making, machine making, and wood working. Zürich is an important center for the manufacture of silk-stuffs and cottons. Cottons are also manufactured extensively at St. Gall, Appenzell, Aargau, and Glarus; the two last named cantons also containing important manufactures of linens, silks, and hosiery. Basel produces silk-stuffs, leather, paper, and tobacco; Neuchâtel, watches and cottons, and Geneva, watches and jewelry.

Commerce.—Although Switzerland is inland, its commerce in proportion to the population has long exceeded that of any other country on the continent of Europe. A Swiss official report for 1894 says, "Switzerland imports each year one-half of that upon which its population subsists. On the other hand it exports about one-third of what it produces. No other nation finds itself in a like situation." In 1895 the leading imports, in the order of their importance, were raw silk, grain, animals, coal, woolen goods, raw cotton, and wine; and the chief countries from which she derived her imports were Germany (which supplied about 29%), Italy, France, Austria-Hungary, Russia, England, and the United States. Her chief exports were, in the order of their importance in 1895, silk goods, cotton goods, watches and cheese, and the leading countries to which Switzerland sent her exports were Germany, with about one-fourth of the export trade, Great Britain, the United States and France. Between 1892 and 1895 there was a customs war between Switzerland and France, which influenced considerably the commerce of the two countries. As to the trade of Switzerland with the United States, it would appear from the figures for 1895 that the latter country sells to S. comparatively little of silk, wool, linen, iron, wood, paper, farm animals, agricultural products and food for animals, but that it does sell considerable amounts of raw cotton, chemical preparations, manufactures of leather, India rubber and raw tobacco. To the United States the leading articles exported from Switzerland are silk and cotton manufactures; food products, such as cheese and condensed milk, and watches and clocks. Germany's large share of Switzerland's trade is due partly to her advantage of situation and partly to the readiness of the German merchant to adapt himself to Swiss trade methods. The American merchants have not shown this adaptability and they have been furthermore hindered by the lack of direct trade communications with Switzerland, almost all of the commodities purchased from the United States in Switzerland reaching that country by way of German or other importing firms. S. imposes duties on imports. Her free list includes such articles as fertilizing materials, garden vegetables and other food products, grass, hay, straw, metallic ores, etc. The foreign traders living in Switzerland are treated in all essential respects in the same way as citizens of the country. The monetary unit is the franc, worth in United States currency 19.3 cents. Nominally S. has the double standard of value, being a member since 1865 of the Latin Union (q. v.). The Swiss federal assembly decides how much gold and silver shall be coined, regulating the issue to conform to the treaty. The coinage of gold was made free and unlimited by the law of Sept. 7, 1889. Paper money is issued by banks under the control of the several cantons and the notes are redeemable in gold or silver.

Government.—Hitherto, the Swiss have been very much split into distinct communities by the great mountain-chains which separate the cantons. One of the results has been the weakness of the central power. Each valley has been intrusted with the making of its own laws, and the management of its own local affairs. The cantons are, in fact,

to this day in a great measure separate states. They are divided into two classes, absolute democracies and representative democracies. In the former the chief power belongs to the *landesgemeinde*, an assembly of the whole adult male population, which meets once a year, to pass laws, and to regulate the taxes and expenditure of the canton. Uri, the Unterwaldens, Appenzell, and Glarus have constitutions of this kind. In the Grisons and the Valais, the people may be said to possess similar powers, as all measures must be approved of by them. In the other, the representative cantons, a great council is elected by the people, and to it are deputed most of the powers of the *landesgemeinde*. These local assemblies produce a remarkable effect on the Swiss people. Their debates have an importance far beyond that of an English town-council, or even of a colonial parliament, for their power is infinitely greater, and the population are more immediately interested in them. To the interest they excite is no doubt to be attributed in a great degree the intelligence and public spirit of the Swiss. Their greatest disadvantage lay in the power they formerly had to levy war against each other, and to resist the general government in conducting the foreign policy of the country. But these defects have been to a great extent remedied by the constitution of 1848, which forms the basis of the present constitution, which dates from 1874. It handed over the control of the army, the conduct of foreign affairs, the settlement of disputes between the cantons, and the management of the police and post-office, to a federal assembly (*bundesversammlung*) representing all the cantons. How far this assembly is entitled to interfere with the legislative action of the cantons, has not been very distinctly defined, but the tendency of legislation since its formation has been rather to trench than otherwise on their prerogatives. The federal assembly consists of two chambers—1st, the state council (*stände rath*); 2d, the national council (*national rath*). The former is composed of 44 members, 2 representing each canton; the latter, of 135 members, elected by the cantons in the proportion of 1 to 20,000 inhabitants. These bodies depute the executive authority to the federal council (*bundes rath*), consisting of seven members, and holding office for three years. The president is merely one of the council, and he has none of the quasi-royal privileges of the American president. There is also a court called the federal tribunal (*bundes gericht*), which acts as a high court of appeal, and consists of 9 members elected by the federal assembly. Different systems of law still prevail in the different cantons, which to some extent resemble each other, the most of them having grown out of the old German codes. Except in a few frontier cantons, the Roman law has not been much regarded. Until 1874 the law of the Catholic cantons prescribed, for certain offenses, various degrees of corporal punishment, exposure on the pillory, and public penance in the churches; but in that year capital and corporal punishment was abolished throughout the confederation. In 1879, the cantonal governments were granted the right to restore capital punishment. There are no titles of Swiss origin, families possessing such distinctions deriving them from abroad. There is no standing army in Switzerland, but every citizen is obliged to serve as a soldier, and military drill is taught at all the schools. See ARMIES. MODERN.

Language, Religion, and Education.—In the sequestered valleys of the Grisons, two-thirds of the population still speak a Latin dialect known as the Romaunsh; Italian dialects have penetrated up the valleys of Ticino; French patois has invaded western Switzerland, by the Rhine and the valleys of the Jura, to Laufen, the frontier of Soleure, lake Morat, the Upper Saane, and Siders in the Valais. In the rest of Switzerland the dialects are German. In no country is elementary instruction more widely diffused. Parents are compelled to send their children to school, or have them privately taught, from six to twelve. There are universities on the German model at Basel, Bern, and Zürich, and academies on the French plan at Geneva and Lausanne.

History.—Switzerland was in Roman times inhabited by two races—the Helvetii, supposed to have been Celts, on the north-west; and the Rætians (of whose origin we know nothing) on the south-east. After the conquest of Gaul, both races adopted the language and habits of Rome. When the invasions took place, the Burgundians settled in western Switzerland; while the Alemanni, another Germanic tribe, took possession of the country east of the Aar. A third Teutonic people, the Goths, entered the country from Italy, and took possession of the country of the Rætians, which nearly corresponded with the Grisons. The Burgundians adopted Christianity in the end of the 5th c.; the Helvetii retained their old pagan creed until the 7th c., when they were converted by Irish monks, who founded abbeys and churches, which survive to our own time. Switzerland, in the early part of the middle ages, formed part of the German empire, and feudalism sprang up in the Swiss highlands even more vigorously than it did elsewhere. During the 11th and 12th centuries, the greater part of Switzerland was ruled on behalf of the emperors by the lords of Zähringen (q. v.), who did much to check civil wars, and to promote the prosperity of the towns. They, however, became extinct in 1218, and then the country was distracted by wars which broke out among the leading families. The great towns united in self-defense, and many of them obtained imperial charters. In 1273, Rudolf of Hapsburg, a Swiss nobleman who had favored the independence of the towns, became emperor. After doing so, he continued the same policy; but his son, Albert I. (q. v.), took another course. He attacked the great towns and was defeated. The leading men of the forest cantons, which for ages had yielded a merely nominal recognition of the empire, and had acknowledged no

feudal superior, met on the Rütli meadow, on Nov. 7, 1307, and resolved to expel the Austrian bailiffs or landvögte. See *TELL*. The war terminated in favor of the Swiss at Morgarten in 1315. Schwyz, Uri, and Unterwalden, with Lucerne, Zürich, Glarus, Zug, and Bern, eight cantons in all, in 1352, entered into a perpetual league, which was the foundation of the Swiss confederation. Other wars with Austria followed, which terminated favorably for the confederates at Näfels (q. v.) and Sempach (q. v.). In 1415, the people of the cantons became the aggressors. They invaded Aargau and Thurgau, parts of the Austrian territory, and annexed them; three years later, they crossed the Alps and annexed Ticino, and constituted all three subject states. The Swiss were next engaged in a struggle on the French frontier with Charles the Bold of Burgundy. They entered the field with 34,000 men, to oppose an army of 60,000, and yet they were successful, gaining the famous battles of Granson and Morat in 1476. In 1481 the towns of Freiburg and Soleure were admitted into the confederacy. In 1499 the emperor Maximilian I. made a final attempt to bring Switzerland once more within the bounds of the empire. He sought to draw men and supplies from the inhabitants for his Turkish war; but in vain. He was defeated in six desperate engagements. Basel and Schaffhausen (1501), and Appenzell (1513), were then received into the confederation, and its true independence began. The abbacy of St. Gall, the cities of St. Gall, Mülhausen, and Bienne became associated states with a vote at the diet. Geneva, Neuchâtel, Valais, and the Grisons, also became associated states, but without a vote.

New troubles sprang up with the reformation. Zwingli began to preach in the beginning of the century, and Zürich, in 1523, adopted his opinions, and was followed by Bern and other cantons of the north. The forest cantons remained attached to the church of Rome. War broke out in 1531 between the Catholics and Protestants, and the former were successful at Cappel, where Zwingli was slain. This victory to some extent settled the boundaries of the two creeds in eastern Switzerland. In 1536, however, Bern wrested the Pays de Vaud from the dukes of Savoy and annexed it to their own territory. In the same year Calvin settled at Geneva, and the reformed doctrines spread throughout western Switzerland. During the thirty years' war Bern, which had become, since the conquest of Vaud, the leading canton, and Zürich, contrived to maintain with great skill the neutrality of Switzerland; and in the treaty of Westphalia, in 1648, it was acknowledged by the great powers as a separate and independent state. At this period the Swiss, in immense numbers, were employed as soldiers in foreign service, and the record of their exploits gives ample evidence of their courage and hardihood. Internally there was great stagnation. The constitution of the larger cantons became more aristocratic, that is to say, the mass of the people lost their power over the governing bodies. In Zürich, Schaffhausen, and Basel the governing councils were elected by the corporations; and in Bern, Freiburg, Soleure, and Lucerne, a few families had acquired permanent rule. At the end of last century there was widespread discontent with this state of matters; but the French revolution broke out, and wars followed, which left no time for its manifestation. In 1798 Switzerland was seized by the French. At the peace of 1815 its independence was again acknowledged. The new confederation was divided into 22 cantons, each of which was represented in a diet, which was appointed to hold its annual meetings alternately at Bern, Zürich, and Lucerne. The old abuses which had crept into the constitutions of the cantons were revived, and representation in most of them became based on property qualifications. Officials, the aristocracy, and the clergy joined to oppose innovations, and succeeded in doing so until 1830, when the French revolution broke out. Armed demonstrations were made against the towns, and universal suffrage was generally conceded. Basel town, however, held out; but the difficulty was settled by the separation of the town and country districts—the former remaining conservative, the latter becoming democratic. Geneva and Neuchâtel retained their old constitutions. The result of the changes was, however, that two-thirds of the whole population were allowed to take part in public affairs. The consequences were not what had been expected by the liberals, who found that they had not yet the means of strengthening the central power. In 1839 at Zürich, where Dr. Strauss had been appointed a professor of theology, a mob of peasants, headed by the Protestant clergy, overturned the government. In Aargau a struggle took place between the liberals and the Ultramontane party, which was settled, after long discussion, by an unsatisfactory compromise. In Valais, where universal suffrage had put power into the hands of the reactionary party, a war took place, in which the latter were victorious. They then ruled with a strong hand, and actually forbade the celebration of Protestant worship within the canton. In Lucerne, the headquarters of the Jesuits, the Ultramontane party acted even more extravagantly; they so persecuted their political opponents that the latter were compelled to leave the canton. These measures caused the greatest discontent. In 1844 a proposal was made in the diet to expel the Jesuits; but that body declined to act. The radical party then determined to resort to force; they organized bodies of armed men, called the free corps, which invaded the Catholic cantons, but they were defeated. Changes favorable to them took place in some of the cantons. The Catholic cantons then formed a league, named the Sonderbund, for defense against the free corps. There was a general clamor for its suppression, but in the diet only 10½ votes were in favor of that measure. The ruling party in Geneva had been with the

majority, and this conduct led to a revolution in that city. One vote was thus gained against the Sonderbund. St. Gall added another; and a majority in the diet in 1847 declared the illegality of the Sonderbund, and decreed the expulsion of the Jesuits. In the war which ensued between the federal army and the forces of the Sonderbund, the former were victorious at Freiburg and Lucerne. The leagued cantons were made liable in all the expenses of the war, the Jesuits were expelled, and the monasteries were suppressed. An attempt was made by diplomatic notes to intimidate the Swiss government, but the revolution of 1848 broke out and prevented further interference. In the same year the radical party, convinced of the necessity of a more powerful central government, carried the constitution of 1848, of which we have already taken notice. Since then the most important event which has taken place in Switzerland was a rebellion against the king of Prussia as prince of Neuchâtel. The canton was declared a republic, with a constitution similar to that of the other Swiss states. The king of Prussia protested vainly, and now retains only the bare title of prince of Neuchâtel. The new constitution of 1874 transferred much power from the cantons to the federal body. In 1888, a diplomatic difficulty arose with Germany owing to the fact that German socialists were harbored in Switzerland. The Swiss government refused to accept the dictation of Germany and took measures to mobilize its forces and strengthen its fortifications, in consequence of which, and because of the moral support given to Switzerland by other governments, the German foreign office adopted a more conciliatory attitude. In 1891, the six hundredth anniversary of the "everlasting league" first entered into by the three forest cantons in 1291, was celebrated by the Swiss with great enthusiasm. See Baker, *The Model Republic* (1895).

SWITZERLAND, a co. in s.e. Indiana, adjoining Kentucky; bounded e. and s. by the Ohio river; about 230 sq.m.; pop. '90, 12,514. Co. seat, Vevay.

SWORD, a well-known weapon of war, the introduction of which dates beyond the ken of history. It may be defined as a blade of steel, having one or two edges, set in a hilt, and used with a motion of the whole arm. Damascus and Toledo blades have been brought to such perfection that the point can be made to touch the hilt and to fly back to its former position. In last century, every gentleman wore a sword; now the use of the weapon is almost confined to purposes of war. In the British army, all officers and sergeants, with troopers of cavalry, wear swords for cutting and thrusting. In the navy, all officers wear similar swords; and the men in time of action, heavy-backed swords, called *cutlasses*. In the French service, nearly all troops wear a combination of the sword with the bayonet, called a sword-bayonet.—For various sorts of swords and their uses, see RAPIER, CUTLASS, BROADSWORD, SCIMITER, SABER, etc.; FENCING. See R. F. Burton's history of *The Sword* (1888).

SWORD-FISH, *Xiphias*, a genus of fishes of the family *scomberidae*, having the upper jaw remarkably elongated and compressed, in the form of a sword or dagger. The body is rather of a long shape, and covered with very small scales. There are no teeth. There is one long dorsal fin. There are no finlets. The ventral fins are wanting. The sides of the tail are very strongly keeled. The tail-fin is large and forked. Only one species is known, *X. gladius*, plentiful in the Mediterranean, and in the warmer parts of the Atlantic; sometimes, but rarely, seen on the British coasts. It is bluish black above, and silvery white on the belly, the one color passing gradually into the other. It is highly esteemed as an article for food, especially when young. It is harpooned by the fishermen of the Mediterranean, and is powerful enough to drag a boat about for many hours after being struck. It has been said to attack the whale with its sword, but this is extremely improbable. Its food consists in great part of squids and cuttle-fish. The use of the sword is unknown. Instances not unfrequently occur of ships' bottoms being perforated by the sword of the sword-fish, but there is no good reason to think that an intentional attack is ever made.

SYBARIS, and **CROTON** or CROTONA, two celebrated Greek colonies in Magna Græcia (q.v.). The former—founded 720 B.C., by Achæans and Trœzenians—was situated in the s. of the Lucanian territory, between the rivers Crathis (*Crati*) and Sybaris (*Cos-cili*) about 3 m. from the Tarentine gulf; and the latter—founded 710 B.C., by Achæans—about 50 m. s.s.e. on the coast of Bruttium. All that is certainly known concerning these cities before the destruction of the former is, that they both rapidly increased in size, wealth, and power, extending their dominions across the peninsula, and founding other colonies, at the same time preserving the most friendly terms with each other. Sybaris is said to have been 6 m. in circumference, and Croton 12 m.; the former being notorious for the excessive and fastidious luxury of its inhabitants (hence the term Sybarite), and the Crotoniates celebrated for the perfection they reached in athletic exercises—the famous athlete, Milo (q.v.), having been a native of Croton. Somewhere between 540 and 530 B.C., Pythagoras (q.v.) settled at Croton, and exercised very considerable influence over the aristocratic government. About 510 B.C., a democratic leader, Telys, deposed the oligarchy of Sybaris, banished 500 of the leading citizens, and assumed the tyranny of the city. The banished citizens having taken refuge in Croton, Telys demanded their surrender, and on being refused, declared war against that city. The Sybarites, with an army said to have amounted to 300,000, met 100,000 Crotoniates, commanded by Milo, at the river Traeis, were completely routed, and their city obliterated by the latter changing the course of the Crathis, so as to sweep

it away. About 443 B.C., Thurii was founded near the site of Sybaris. After the destruction of Sybaris, Croton appears to have gradually declined, suffering much from internal convulsions (see PYTHAGORAS), as well as from the disasters which befell it in its wars with the Locrians, Rhegians (480 B.C.), and Bruttians, and also in those of Dionysius (q.v.) of Syracuse and Pyrrhus (q.v.). Its ruin was completed in the second Punic war; and although, in 194 B.C., it was colonized by Roman citizens, it never again rose to be a place of any importance. Croton, in the time of Herodotus, and at a later period, was famous as a medical school.

The modern town of Cotrone, standing very near the site of the ancient town, had a pop. (1881) of 6484.

SYBEL, HEINRICH VON, German historian, was born in Düsseldorf, Prussia, in 1817; studied under Von Ranke at the University of Berlin and took his degree at Bonn, where he subsequently became Extraordinary Professor, and in 1845 Professor of History at Marburg. In 1847, he was elected to the Hessian legislature, and later to the Diet of Erfurt. In 1856 he was invited to Bavaria by the king, and became a member of the Academy of Sciences in Munich. In 1861, he was called to the chair of history at Bonn, whence he was sent to the Prussian House of Deputies, and in 1866 to the Constituent Diet of the North German Confederation. He became director of the Royal Prussian Archives in 1875, a post that gave him the amplest facilities for prosecuting his historical researches. His great works are, *A History of the First Crusade* (1841), *A History of the French Revolution, The Rising of Europe against Napoleon I.* (1860), and *The Founding of the German Empire by William I.* (7 vols. Munich, 1889-94), which was translated into English (1891). He died in 1895.

SYCAMINE, a tree mentioned in Scripture, and supposed to be the black mulberry (q.v.).

SYCAMORE, or SYCOMORE, *Sycomorus*, a genus of trees of the natural order *moraceæ*, regarded by many botanists as a mere sub-genus of *figus* (see FIG), and differing from the true figs only in the elongated, straight, thickened, and club-shaped stigma. The species are chiefly African, but the geographical range extends also into the w. of Asia. Some of them attain a large size and a great age. The EGYPTIAN SYCAMORE (*S. antiquorum* or *figus sycamorus*), supposed to be the sycamore of the Bible is a large tree, very abundant in Egypt and in some parts of the w. of Asia, often planted near villages for the sake of its shade, its wide-spreading head sometimes covering a space 40 yards in diameter. The figs are top-shaped, and grow in clustered racemes on the trunk and oldest branches. They are sweet, well-flavored, and somewhat aromatic.

The sycamore tree of Britain is a species of maple (q.v.). In some parts of North America the same name is given to the plane (q.v.) of that country, *platanus occidentalis*.

SYDENHAM, a suburb of London, county of Kent, 7 m. s. of London. It has become of world-wide celebrity in connection with the Crystal Palace (q.v.), which was erected here in 1854, chiefly from the materials of the building of the great exhibition (1851). Pop. '91, 34,162.

SYDENHAM, THOMAS, a great English physician, was born of good parentage, in 1624, at Winford Eagle, Dorsetshire, and was educated at Magdalen hall, Oxford. According to the well-known French surgeon, Desault, he afterward studied at Montpellier. He graduated at Oxford as bachelor in medicine in 1648. Through the interest of a near relative, he obtained a fellowship of All Souls' college, and there continued to prosecute his medical studies. He left the university without taking a doctor's degree, which, indeed, he did not obtain till some time afterward at Cambridge. He settled as a practitioner at Westminster, and practiced so successfully that, when only 36 years of age, he already enjoyed the reputation of being one of the first physicians of the period. In his later years he was much afflicted by gout, which at length carried him off on Dec. 29, 1689. He was buried in St. James's church. Sydenham was not profoundly accomplished as a man of science; even in his own age, deficient as it was in the advanced development to which the researches on which medicine is based have now attained, he was inferior to several of his contemporaries; but in sagacity of observation and accuracy of diagnosis, he was unsurpassed. His skill and his philosophic cast of mind secured him the admiration and friendship of Locke; and his contributions to the literature of his profession received the praise of Haller and Boerhaave. His writings have been often republished both in England and on the continent, the edition entitled *Opera Medica*, which appeared at Geneva in 1716, being the best. Fevers were the department of medicine on which he first bestowed his attention; and before he had been many years in practice, he published, in 1666, his celebrated treatise entitled *Methodus Curandi Febres Propriis Observationibus Superstructa*. This was afterward reprinted in 1675, with the observations accumulated in the interval. His treatment of the then destructive malady of small-pox was especially felicitous, substituting, as he did, for the stimulating regimen in vogue, the antiphlogistic method of cool air and salines.

SYDNEY, the capital of New South Wales, and the oldest city in Australia, is situated on the southern shores of Port Jackson, in lat. 32° 52' s., long. 151° 13' e. The first party of British settlers that reached New Holland were landed at Botany Bay on Jan. 20, 1788. The spot which they here selected being found ineligible, it was abandoned a few days afterward, and the infant settlement was transferred to a point about 7 m. further to the n., to the place where Sydney now stands. The choice of the new locality

was chiefly determined by the circumstance of a stream of fresh water being found there, flowing into the deep inlet known as Sydney Cove, one of the numberless bays into which the basin of Port Jackson is divided. This last-mentioned magnificent expanse of water, completely land-locked, and admitting vessels of the largest size, extends for some 20 m. inland, ramifying in every direction. Its bold and rocky shores present a succession of picturesque and beautiful landscapes. The cliffs which form the general outline of the harbor often rise to a height of from 200 to 250 ft. In other points, the coast presents a lower level, consisting of a series of terraces and smooth sandy beaches. Perhaps there are few positions on the habitable globe more obviously suitable for the foundation of a great metropolis. Situated at a distance of about 8 m. from the sea; the whole bay round which it is built forms a fine harbor, where the largest vessels can safely anchor. The narrow entrance of Port Jackson — through what is called the "Heads" — might easily be made inaccessible to any hostile fleet; whilst the central position of Sydney makes it necessarily the permanent emporium of the greater number of the British dependencies in the southern hemisphere. The immense coal formation of east Australia extends n. and s. for some 500 m., with a breadth of from 80 to 100 miles. Sydney stands nearly in the center of this great carboniferous basin; and at various points within a radius of from 30 to 100 miles, large quantities of coal are raised for colonial consumption as well as for export. The sandstone rock upon which the city is erected affords a valuable material for building.

Since the abolition of transportation, the growth of Sydney has been rapid, the pop. in 1862 amounting to 93,596, and in 1895 to 408,500 (est.), including the suburbs. For many years Sydney enjoyed a monopoly of the commerce of these antipodean regions. It has now formidable rivals in Melbourne, Adelaide, and the settlements of Queensland. It must, however, continue the exclusive outlet for the productions and commerce of extensive pastoral and mineral districts on the n.w., w. and southwest. The eastern shore of Darling harbor has its frontage entirely occupied with wharves and quays.

The streets in the older parts of the town are narrow and irregular; in the newer portions care has been taken to avoid these defects; and several of the modern streets, from their breadth and the size and style of the buildings, are not behind those of the principal towns of Europe. The shops, warehouses, and private buildings in George and Pitt streets present long and compact lines of well-built stone edifices, often assuming a very ornate and ambitious style of architecture. The chief thoroughfares are paved, and a system of underground drainage has been carried out at a cost of nearly half a million sterling. Plans have been concluded to bring water from a point on the Nepean river, 63 m. distant, to a large reservoir at Paramatta. A sewer is in process of construction in which all sewage will be conducted to the ocean shore. There are fine botanical gardens, and a number of public parks. The Fitzroy dry-dock, originally intended for vessels of the royal navy, can take in vessels of the largest size. Lately steps have been taken to put the city in a state of defense, and forts and batteries armed with powerful Armstrong guns have been erected. The climate of Sydney is, upon the whole, temperate and healthy.

Among public buildings, by far the most important edifice, not only in Sydney, but in the whole of the Australian settlements, is the university, which stands on a commanding height, and in the center of a domain of about 150 acres. The principal façade is 500 ft. in length, and is flanked at its western end by the great hall, the proportions of which are such that, were it in England, it would rank as the third in point of size. Lectures are delivered daily during each term on classics, logic, history, chemistry, natural and experimental philosophy, and jurisprudence. The museum contains a collection of Greek, Roman, and Egyptian antiquities presented by the former chancellor, Sir C. Nicholson. There are two suffragan colleges in connection with the university — that of St. Paul's, belonging to the church of England; and St. John's, erected under the auspices of the Roman Catholic community. The university is incorporated under an act of the colonial legislature and by royal charter. It is only empowered, however, to confer degrees in arts, law, and medicine; and, so far as the university is concerned, instruction is limited to purely secular teaching. Its degrees rank with any of the English universities. The religious training of the pupils is left to the affiliated colleges. The metropolitan cathedral of St. Andrew is a handsome building in the later perpendicular style of architecture. Many of the churches, upward of 120 in number, belonging to different religious denominations, are tastefully designed. Among the buildings devoted to secular purposes, the most imposing and effective, in point of size and architectural design; are the residence of the governor, the museum, the exchange, the custom-house, the town-hall, the new post-office, and the public grammar-school. The neighborhood of Sydney, with every nook in the adjacent bays, is studded with elegant villas and snug cottages, surrounded by their park-like grounds, and gardens of orange trees, bananas, and numberless semi-tropical plants unfamiliar to the English eye of the newly-arrived immigrant. There are numerous manufactories of wagons, glass, pottery, boots and shoes, railroad manufactures, carriages, stoves, tobacco, and there are distilleries and breweries. Sydney has theaters, several mechanics' institutes, a large hospital for the sick, an orphan asylum, and other charitable and benevolent institutions, all liberally endowed and supported by public grants or private munificence. There are a number of suburbs: Balmain in the w., Newton, Redfern, Marriekville and Waterlow in the s., Paddington, Randwick, Woolhara and Waverley in the e. The more fashionable suburbs are those in the eastern portion.

SYDNEY, a seaport town of Nova Scotia, on the e. part of the island of Cape Breton, and formerly capital of the colony of Cape Breton; the terminus of the intercolonial railroad; 285 m. n.e. of Halifax. It is on one of the finest harbors in the world, with an excellent entrance, on the s. side of which is a lighthouse with a fixed light 160 feet above the sea. The town has a railroad connecting it with the noted Bridgeport coal mines, where the coal vein is 9 feet thick, and has considerable trade with Newfoundland and the islands of St. Pierre and Miquelon. There are several churches, branch bank, masonic hall, hotels, sash and door factories, court house and jail, weekly newspapers, and numerous stores. The town and harbor constitute the North American station of the French navy. Pop. '91, 2435.

SYDNEY, ALGERNON. See **SIDNEY**.

SYENE. See **ASSOUAN**.

SYENITE, a granitic rock found near the city of Syene, in Egypt. It is composed of quartz, feldspar, and hornblende, and differs from true granite in having the mica replaced by hornblende. The feldspar is generally red (sometimes it is found of a white color), and the hornblende gives a mottled red and dark green color to the rock.

SYKES, GEORGE, b. Del., 1822; graduated at West Point, 1842; commissioned in the infantry and served in the Seminole and Mexican wars, behaving with great gallantry at Cerro Gordo. He was afterward employed on the frontier, and in 1861 was in Texas with rank of captain. He was present at Bull Run, and in the Virginia campaign in command of regular troops, and also at Antietam, Fredericksburg, Chancellorsville, and Gettysburg; and was brevetted maj. general. In 1866 he was mustered out of the volunteer service, and became a col. in the regular army. He d. 1880.

SYKES, OLIVE (LOGAN), b. New York, 1841; at the age of 13 made her debut on the stage in Philadelphia; wife of Edmund A. Delille, 1857-65, went to Europe in 1857; was educated in England, and contributed to English and French papers. In 1864 she appeared at Wallack's Theatre, New York, in *Eveleen*, a play of her own composition; retired from the stage in 1868, and appeared on the platform as a lecturer on woman's rights, pursuing her former calling of newspaper correspondent and magazine writer. In 1871 she became the wife of William Wirt Sykes (d. 1884), U. S. consul at Cardiff, Wales. She has published essays and lectures.

SYLLABUB, a culinary preparation, formerly much more used than at present. It consists of sugar and cream flavored with brandy, sherry, and lemon rind and juice, worked into a froth, and served up in that state in glasses.

SYLLABUS, a document published by Pope Pius IX., 1864, condemning as heresies 80 doctrines which it calls "the principal errors of our times," dividing them into 10 sections; the 1st includes pantheism, naturalism, and absolute rationalism; the 2d, moderate rationalism; the 3d, indifferentism and latitudinarianism; the 4th, socialism, communism, secret societies, Bible societies, and other "pests of this description;" the 5th, errors concerning the church and her rights; the 6th, errors concerning civil society; the 7th, errors concerning natural and Christian ethics; the 8th, errors concerning Christian marriage; the 9th, errors concerning the temporal power of the pope; the 10th, errors of modern liberalism. Among the things thus denounced as errors are the principles of civil and religious liberty, and the separation of church and state. The document virtually declares that the pope is infallible; that Romanism has the exclusive right of being recognized by civil governments; that all other forms of religion are unlawful; that the papal hierarchy is independent of all civil authority, and that the Roman church has supreme control over education, literature, and science; with the right to enforce submission to its decrees.

SYLLOGISM, a name expressing a principal branch or department of logic. When we reason, or get at truth by means of inference, we are said to proceed either inductively (see **INDUCTION**) or deductively. Deductive reasoning, when fully and methodically expressed, takes the form called the syllogism. "This thing will sink in water, for it is a stone," is a deductive argument, but not fully stated; the complete form is: "Stones sink in water; this is a stone; therefore, this will sink in water"—which form is called a syllogism. See **LOGIC**.

To a perfect syllogism it is necessary that there should be three, and no more than three, *propositions* (see **PROPOSITION**); these are the conclusion, or the matter to be proved, and two others that are the means of proving it, called the premises. It is also necessary that there should be three, and no more than three, *terms*, namely, the subject and the predicate of the conclusion, and one, called the middle term, which must occur in both premises, being the connecting link for bringing the two other terms together in the conclusion. The *predicate* of the conclusion is called the major term, because it is in its scope the largest of the three; the *subject* of the conclusion is the minor term, as being the smallest in scope. The three terms enter into the premises in this manner: the major term and middle term make one premise, called the major premise; the middle term and the minor term make the minor premise. In the syllogism above stated, the terms are, "a thing that will sink in water" (major), "this thing" (minor), "stone" (middle); the premises are, "stones sink in water" (major), "this thing is a stone" (minor); the conclusion is, "this thing will sink in water."

The form now given, although the regular and fundamental form to prove any affirmative conclusion, is not the only form that an argument may assume. The totality of syllogistic forms is divided into *figures*, and each figure into *moods*, which are the distinct syllogistic forms, the principle of division being as follows: the figure is determined by the position of the middle term, which may be the *subject* of the major premise, and the *predicate* of the minor (1st figure), the *predicate* in both (2d figure), the *subject* in both (3d figure), the *predicate* of the major and the *subject* of the minor (4th figure).

The word "figure" is borrowed from rhetoric, where it means a departure from plain and ordinary speaking, as metaphor, hyperbole, etc. But, as remarked by Hamilton, only the last three of the foregoing enumeration should be called "figures." The first should be considered as embracing the regular forms of reasoning, and the others as properly figures—that is, forms more or less inverted, irregular, or unnatural, although still correctly representing reasonings that actually occur. These forms may be all *reduced* to forms in the 1st figure; their inversions or distortions being, as Hamilton would say, *redressed*, or restored to the primitive or fundamental type, namely, the syllogisms of the 1st figure.

The 4th figure did not belong to the original scheme of Aristotle, and it is usually considered as both unnatural and unnecessary, being only an awkward inversion of the first. There would then be the natural or standard syllogisms (the 1st fig.), and two sets of figurative departures from them (2d and 3d figs.).

The syllogisms of each figure are said to differ in *mood*, or according to the *quality* and the *quantity* of the propositions—that is, according as these are affirmative or negative (quality), universal or particular (quantity).

The entire scheme may be presented as follows: The symbols used are P (predicate of conclusion), major term; S (subject of conclusion), minor term; M, middle term. The general type of the first figure or standard is:

M is P.
S is M.
S is P.

When the quality and the quantity of the propositions are expressed, there arise four syllogisms of this form—two affirmative, and two negative:

All M are P.
All (or some) S are M. } *Barbara, Darii.*
All (or some) S are P.

All matter gravitates.
All (or some) air is matter.
All (or some) air gravitates

No M is P.
All (or some) S is M. } *Celarent*
No S is P; some S is not P. } *and Ferio.*

No matter is destructible.
All (or some) air is matter.
No air is destructible; some air is not destructible.

The general scheme of the 2d figure is:

P is M.
S is M.
S is P.

There are four syllogisms in all, which we may take in pairs thus:

No P is M.
All (or some) S are M. } *Cesare*
No S is P; some S are not P. } *and Festino.*

"No destructible thing is matter," etc., as in the last form.

All P is M.
No S is M; some S is not M. } *Camestres*
No S is P; some S is not P. } *and Baroko*

In this figure there is a certain distortion of the previous or regular figure. In the first of the two pairs, the major is, No P is M, instead of the equivalent (1st figure), No M is P. In the first form of the second pair, the minor is, No S is M, instead of the equivalent, No M is S, which should be the major to be regular; the amended premises would then give, in conclusion, No P is S, equal to No S is P.

All matter is extended. }
No mind is extended. } *Camestres.*
No mind is matter.

The last form, with a particular conclusion, is exemplified thus:

All matter is extended.
Some things are not extended.
Some things are not matter.

This is a form technically called *Baroko*, which is one of two that are especially difficult to reduce to the standard forms.

This figure proves only negatives.

The scheme of premises in the 3d figure is

M. P.
M. S.

Six varieties of syllogism come under this figure; we may arrange them in three pairs, the first two pairs having the same major, and the third the same minor:

All M is P.
All (or some) M is S. } *Darapti*
Some S is P. } and
 Datisi.

All planets move.

All (or some) planets are heavenly bodies.

Some heavenly bodies move.

No M is P.
All (or some) M is S. } *Felapton*
Some S is not P. } and
 Ferison.

No solid body is perfectly transparent.

All solid bodies gravitate.

Some gravitating things are not perfectly transparent.

Some M is P; some M is not P. } *Disamis*
All M is S. } and
Some S is P; some S is not P. } *Bokardo.*

The first of the two is merely a standard syllogism (*Darii*), with transposed premises, the second (*Bokardo*) is more complicated, as in the example:

Some men are not fit to rule.
But all men are liable to have dominion.
Some men, liable to have dominion, are not fit to rule.

In the 4th figure,

P is M,
M is S,

there are five syllogisms. The mere forms are enough to quote:

All P are M. }
All M are S. } *Bramantip.*
Some S are P. }

All P are M. }
No M is S. } *Camenes.*
No S is P. }

Some P are M. }
All M are S. } *Dimaris.*
Some S are P. }

No P is M. }
All M are S. } *Fesapo.*
Some S are not P. }

No P is M. }
Some M are S. } *Fresison.*
Some S are not P. }

The reasons why these syllogisms are true, and why no other of 256 possible combinations of propositions can give true conclusions, are certain laws, called the rules of the syllogism, which repose on first principles of the highest certainty.

Mr. Mill has laid down the following fundamental axioms of the syllogism, as stated in its standard forms in the first figure. (1.) "Attributes coinciding with the same attribute, coincide with one another." M, the middle term, coincides with P, the predicate; S, the subject, coincides with M; therefore S and P coincide with one another. (2.) "Any attribute incompatible with a second attribute, is incompatible with whatever that second attribute coincides with." No M is P; M is incompatible with P; but S coincides with M, and therefore it also is incompatible with P.

All the syllogisms of the last three figures are reducible to the first, by conversion of

propositions and transposition of premises, according to the nature of the case. The symbolic name of each syllogism contains instruction for this process, as well as stating the composition of the syllogism. To aid the memory, these symbols are put together in five Latin hexameter verses of very ancient but unknown origin:

"Barbara, Celarent, Darii, Ferioque prioris.
Cesare, Camestres, Festino, Baroko, secundæ.
Tertia Darapti, Disamis, Datisi, Felapton,
Bokardo, Ferison habet, quarta insuper addit
Bramantip, Camenes, Dimaris, Fesapo, Fresison."

The first line gives the standard figure, and states the propositions entering into each syllogism. The three A's in Barbara are three universal propositions. The E, A, E, in Celarent, are a universal negative, a universal affirmative, a universal negative; in Darii, A, I, I, a universal affirmative and two particular affirmatives, etc. In the other figures the commencing letter (C, B, etc.) shows which standard syllogism each is to be reduced to (Baroko to Barbara, Cesare to Celarent, etc.). The consonant *s* means simple conversion of the proposition marked by the preceding vowel; *p* means conversion by limitation, or *per accidens*; *m* signifies the transposition of the premises; *k* occurs in Baroko and Bokardo, and denotes that these are to be reduced by supposing the conclusion false, and then showing that on that supposition Barbara would be contradicted—from which it is inferred that the original form is true.

There are some species of deductive arguments that do not fall under the syllogistic figures. Thus, the major may state a conditional proposition, and the minor affirm the truth of the condition. "If the witness is to be believed, the man is guilty" (major); now "the witness is to be believed" (minor); therefore "the man is guilty." A true conclusion would also be obtained by a minor denying the consequent, "the man is not guilty." It would then follow that the witness (who affirms his guilt) is not to be believed. But no conclusion would follow from either denying the condition, "the witness is not to be believed," or affirming the consequent, "the man is guilty," for, in the first place, the man might be guilty whether this particular witness be credible or not; and secondly, the guilt of the man does not prove the credibility of the witness. This is called the *conditional* syllogism.

Again, the major may be what is called a disjunctive or alternative proposition, from which also inferences may be drawn by supplying certain minors. "This was done by either A or B," now "it was not done by A (or by B);" therefore "it was done by B (or by A)." Should the major be understood to mean that it was done by one, and not by both, there would be two other possible inferences. "It was done by A (or by B);" therefore "it was not done by B (or by A)." There are other disjunctive pairs, as for example: "Either A is B, or C is D;" now "A is not B, therefore C is D," etc. This is called the *disjunctive* syllogism.

A combination of the conditional and the disjunctive makes the *dilemma*. For example:

If A exist, then either B or C exists.
Neither B nor C exists.
Therefore A does not exist.

The following dilemma was given to refute the practice of torturing witnesses: "A person able to endure pain will be likely to utter falsehood under torture; one unable will be equally likely; therefore, a person under torture will be likely to utter falsehood."

A very great enlargement has been given to the doctrine of the syllogism by sir W. Hamilton (see QUANTIFICATION), Prof. De Morgan, and the late Prof. Boole of Cork. They have shown that many more syllogistic pairs can be created, and have invented symbols for the purpose. It is, however, comparatively few, either of the old pairs or of the new, that are assumed by the ordinarily occurring arguments, either in the sciences or in common affairs. By far the most useful part of the syllogism is contained within the limits of the first or standard figure, which shows what premises are to be looked out for to prove any conclusion; namely, some *general assertion* of matter of fact, affirmative or negative (major), and a *particular assertion* that a given thing comes under the subject of the general assertion (minor), and therefore falls likewise under its predicate. When an argument is stated in a puzzling or perplexed form, with perhaps the omission of one of its essential propositions, it is well to know how to supply the suppressed premises, and put the argument into regular order: the truth or fallacy of the reasoning then becomes evident at a glance.

SYLPHS, in the fantastic system of the Paracelsists, are the elemental spirits of the air, who, like the other elemental spirits (q.v.), hold an intermediate place between immaterial and material beings. They eat, drink, speak, move about, beget children, and are subject to infirmities like men; but, on the other hand, they resemble spirits in being more nimble and swift in their motions, while their bodies are more diaphanous than those of the human race. They also surpass the latter in their knowledge, both of the present and the future, but have no soul; and when they die, nothing is left. In form they are ruder, taller, and stronger than men; but stand nearest to them of all the elemental spirits, in consequence of which they occasionally hold intercourse with human creatures, being especially fond of children, and of simple harmless people; they even

marry with our race, like the undines and the gnomes, and the children of such a union have souls, and belong to the human race.

In common usage, the term sylph has a feminine signification, and is applied to a graceful maiden. How this curious change of meaning occurred is not quite certain; but it is probably owing to the popularity of Pope's *Rape of the Lock*, which introduced the term into the world of fashion and literature. For although even in Pope, the sylph that guards Belinda is a *he*, yet the poet so refined and etherealized his spiritual agents, that they soon came to be associated with all our ideas of feminine grace and beauty, and this circumstance may have reacted on the popular idea—always loose and inaccurate—of their character and sex, and brought about the change of gender to which we have alluded. See Paracelsus's *Liber de Nymphis, Sylphis, Pygmaeis et Salamandris et Cæteris Spiritibus* (Basel ed. of Paracelsus's works, 1590).

SYLVESTER, the name of two popes, and of a third who was an anti-pope. The pontificate of the first immediately succeeded that of Melchiades in 314, and is memorable for the great council of Nicæa, in which the heresy of Arius was condemned. Sylvester himself did not attend the council, but sent two priests—Vitus and Vicentius—to take his place. His name is also celebrated in connection with the so-called donation of Constantine to the Roman church, the spuriousness of which (although no doubt had been raised regarding it during many centuries) has long been admitted by critics. He died in 335. Sylvester II., one of the most learned of the mediæval popes, originally called Gerbert, was b. at Aurillac, in Auvergne, early in the 10th century. He was educated in the monastery of his native village; but went early to Spain, where he learned mathematics, and afterward to Rome. He was appointed abbot of the monastery of Bobbio, where he taught with much distinction and success. At a later period he went to Germany as preceptor of the young prince Otho, afterward Otho II.; and ultimately became secretary to the archbishop of Rheims, and director of the cathedral school, which became eminent under his care. The archbishop having been deposed, Sylvester was elected to the archbishopric; but he was afterward set aside, the deposition of his predecessor having been declared invalid. In the year 998, however, he was appointed archbishop of Ravenna, whence he was called to the pontifical throne, in the following year, under the name of Sylvester II. He was a man of rare acquirements for his age. He was an adept in mathematics, and in practical mechanics and astronomy, in which department his attainments acquired for him among his contemporaries the evil reputation of a magician. He is also believed to have been acquainted with Greek, and perhaps with Arabic. Of all his works, which were numerous, his letters (printed by Du Chesne in the *Historians of France*) have attracted most notice from the light they throw on an obscure period.

SYLVESTER, Prof. JAMES JOSEPH, F.R.S. (1814-97), Savilian Professor of Geometry in the University of Oxford. After a distinguished college career he attained the position of Second Wrangler in 1837, but owing to his Jewish origin could not take his degree. While professor at University College, London, he received a call from the Johns Hopkins University, Baltimore. He succeeded (1883) Professor H. Smith in the professorship at Oxford. He was Hon. Fellow of St. John's College. He received in June, 1890, the Hon. LL.D. degree at Cambridge. He has written many sonnets; is the author of *The Loves of Verse* (1870), and the inventor of the "improved pantograph."

SYLVESTER, JOSHUA, b. England, 1563. His life was divided between the somewhat incongruous pursuits of merchandise and poetry, in neither of which did he achieve a distinct success. Of his original works, the human memory retains no trace; but in virtue of the great, though fleeting popularity obtained by his English version of the *Divine Weeks and Works of Du Bartas*, from which Milton is thought to have derived some hints, he lives in literary history as a sort of *nominis umbra*. He died in 1618.

SYLVIADÆ, a family of birds, of the order *insectores*, and tribe *dentirostres*, including a very great number of small species, among which are many of the birds most noted for sweetness of song, while some of this power is possessed by almost all the family, so that the name *warblers* is often used as synonymous with sylviadæ. The bill is sharp, slender, straight, and rather compressed toward the tip; the wings moderately long; the legs slender. To this family belong the nightingale, the blackcap, numerous species known by the name of warbler, the redbreast, redstart, wheatear, whitethroat, stonechat, whinchat, golden-crested wren, hedge-sparrow, etc. The sylviadæ are diffused over all parts of the globe.

SYMBOLIC BOOKS, in the language of the church, is a phrase that signifies the same as creeds and confessions (q.v.). The name is derived from the Greek *symbolon*, a sign or mark by which anything is known—a creed being the distinctive mark or watchword of a religious community.

SYMBOLISM. The name given to a curious principle adopted by a school of modern French poets, who affect to set forth their sentiments and meanings, not directly, but in a sort of obscure simile or allegory. Thus a poet depicts a house in which funeral rites are going on, while the pall is laid over the furniture. This is supposed to symbolize the death of poetry and the substitution of music in its place. The extreme symbolists complicate their allegories with what they call "poetic instrumentation"—the theory that the syllables of the French language evoke in us the sensation of different colors and consequently (a beautiful *non sequitur*!) the *timbre* of different instruments. It

is unnecessary to say that no symbolism is wholly comprehensible to any but its own originator, and that the whole theory is morbidly unreal, belonging to the epigene sect known in Paris as the *décadents*. The chief symbolists are Hector Mallarmé, Arthur Rimbaud, Gustave Kuhn, and especially Paul Verlaine. See George Moore's *Confessions of a Young Man*, pp. 51-55 (Amer. ed. 1890), and Nordau's *Dégénérescence* (Eng. trans. N. Y. 1894).

SYMBOLS OF THE EVANGELISTS. See EVANGELISTS, SYMBOLS OF THE.

SYME, JAMES, was born in 1799, in the county of Fife, and received a thorough education in art and medicine, in the University of Edinburgh. In his 19th year he began his anatomical studies under Liston, who appointed him his demonstrator. From 1825 to 1832 he lectured on surgery in the Edinburgh School, and, while generously refusing to lecture in opposition to his old master in the Edinburgh Infirmary, he established a hospital at his own expense, where he delivered a clinical course for four years. In 1831, appeared his well-known treatise on *The Excision of Diseased Joints*; and in 1832, his *Principles of Surgery*, which has since gone through many editions, and which has established his reputation as a teacher of the first rank. In 1833, he was elected to the chair of surgery in the university of Edinburgh, which he filled with the highest distinction. In 1847, he gave up his Edinburgh chair to fill that vacated in London by the death of Liston; but collegiate misunderstandings induced him, after six months, to return to Edinburgh. As an operator, Mr. Syme had no superior; as a teacher, he had no equal. His innovations in the practice of his art were characterized by so much ingenuity, controlled by scientific caution, that they were adopted by all really great surgeons. The best of his pupils, who are numerous, and scattered over every quarter of the globe, have been heard to declare that their soundest ideas in surgery are derived from Syme. Besides the works already named, he was the author of valuable treatises on diseases of the rectum; on the pathology and practice of surgery; on the urethra and *fistula in perineo*; on incised wounds, etc. He died June 26, 1870.

SYMMACHUS, Q. AURELIUS, a distinguished Roman orator, scholar, and statesman who flourished toward the close of the 4th c., was educated in Gaul, and after holding several lesser offices, became prefect of Rome (384 A.D.). Seven years later he was raised to the consulship. The date of his death is unknown, but we know that he was alive in 404 A.D. The character of Symmachus is a very fine one. A sincere pagan in an age when classic paganism was almost extinct, he proved in his own person a pattern of its choicest virtues, and manfully, if in vain, strove to regain for it a place of honor in the state. Symmachus's extant writings consist of ten books of letters (*Epistolarum Libri X.*) and the fragments of nine orations. The former were published after his death by his son, and contain not a little that is valuable in relation to the history of the period; but the style is in general a slavish imitation of Livy. The best editions of the epistolæ are those of Scioppius (Mainz, 1608) and Seeck (Berlin, 1883). The fragments of the orations were first discovered by Cardinal Mai in a palimpsest of the Ambrosian Library, and were first published at Milan in 1815; afterward, with some additions, at Rome in 1823, in *Scriptorum Veterum Nova Collectio*. See Morin's *Etude sur la Vie et les Ecrits de Symmaque, Préfet de Rome* (Par. 1847); and Seeck's edition (Berlin, 1883).

SYMMES, JOHN CLEVES, 1780-1829, b. N. J.; in 1802 he became an ensign in the U. S. army, and served with credit in the war of 1812. After the close of the war he became a resident of Newport, Ky., and spent his time in studying, writing, and lecturing on scientific and geographical subjects. He acquired some notoriety by his extraordinary theory that there is an opening at each of the poles, leading into the center of the earth, which he thought was hollow, and capable of habitation. He wrote *Theory of Concentric Spheres* (1826).

SYMMETRY OF ORGANS. Throughout the animal kingdom, a symmetry of organs very generally prevails in the two sides of the body. This is the case in man and in all the *vertebrata*; more perfectly, however, in the external than in the internal organs, the two sides of the body presenting great diversities in the circulating, digestive, and other systems. Even the external organs, although similar on the two sides, are never perfectly so. On comparing the two hands, for example, the veins of the one will be seen to differ from those of the other. In *mollusca*, the symmetry of the two sides sometimes exists, and is sometimes entirely lost, the one side remaining undeveloped in the growth of the animal. In the *articulata*, the symmetry is in general as perfect as in the *vertebrata*, and in the internal structure even more so. In the *radiata*, the whole type is very different, and a very different kind of symmetry appears, not with reference to two sides, but to the rays into which the body divides.

In the vegetable kingdom, a symmetry is found, more or less perfect, but never completely so, between the two sides of leaves, fronds, etc. In flowers, a symmetry appears in the regular distribution of sepals, petals, stamens, etc., around the center of the flower; and even in the buds of those flowers which least exhibit it when fully blown.

SYMONDS, JOHN ADDINGTON, was born at Bristol, England, October 5, 1840. He was educated at Harrow School, and Balliol College, Oxford. In 1862, he received a fellowship in Magdalen College, Oxford; but for many years on account of ill-health he resided at Davos-platz, in Germany, and devoted himself wholly to literature. Among his principal works are, *Introduction to the Study of Dante*; *Studies of the Greek Poets* (2 vols.); *Sketches in Italy and Greece*; *Renaissance in Italy* (seven volumes, completed in 1896); *Shelley and Sir Philip Sidney* in the *English Men of Letters Series*; the

article on *Italian History* in the *Encyclopædia Britannica*; *Many Moods* and *New and Old* (volumes of poems); *Animi Figura* (sonnets); *Italian By-ways*; and *Walt Whitman* (1893). Died 1893.

SYMPATHETIC INK. See INK.

SYMPATHY (Gr. *sympâttheia*, fellow-feeling) may be defined as the assumption by different individuals, or by different parts of the same individual, of the same or an analogous physiological or pathological state at the same time or in rapid succession. The late Dr. Todd (art. "sympathy" in the *Cyclopædia of Anatomy and Physiology*) divides all the examples of sympathy which are included in the above definition into three classes; first, sympathies between different individuals; secondly, those which affect the mind, and, through it, the body; and, thirdly, those which are strictly organic.

As examples of the *first class* may be mentioned the readiness with which the act of yawning is induced in a company, if a single person begins to yawn; the facility with which hysterical convulsions are induced in a female hospital ward by a single case; the fascination of its prey by the serpent, apparently by the power of the eyes; the similar power exerted by so-called electro-biologists and mesmerists, and by which some men can control even the fiercest carnivora. Of these sympathies the only explanation that can be given is that suggested in the article on Animal Magnetism (q.v.). As examples of the *second class*, the following cases may be adduced: certain odors—as of strawberries, mutton, cats, and other most diverse objects—will induce fainting in some people; the smell of a savory dish will excite a flow of saliva in the mouth of a hungry person; and the excitement of the emotions of pity will produce a copious flow of tears. In these cases, an affection of the mind is a necessary link, but why that affection of the mind should produce its peculiar effect, is a question not easily answered; but it is plain that the portion of the nervous center which is affected in such cases, must have a direct influence upon the parts in which the sympathetic phenomena appear, through commissural (or connecting) fibers, or the continuity of its gray matter with that of the center from which its nerves immediately spring. Examples of the *third class* occur in the pain in the knee which arises from disease of the hip-joint; the pain in the right shoulder from disease of the liver; the pain over the brow on taking a draught of iced water into the stomach; the various spasmodic affections connected with intestinal irritation, or the irritation of teething; the vomiting that occurs on the passage of a biliary or renal calculus, etc. All these cases may be more or less satisfactorily explained by the known laws of the sensory and motor nerves. In some of these cases the explanation, however, cannot be regarded as altogether complete. For example, the pain over the brow from the ingestion of cold water or ice into the stomach, may be referred to irritation of the gastric branches of the pneumogastric nerves communicated in the medulla oblongata to the fifth nerve; but why the irritation should be confined to the frontal branch of the first (or ophthalmic) division of the fifth nerve, we are utterly unable to explain.

SYMPHONY, in music, a word used in two different senses: 1. The instrumental introduction and termination of a vocal composition, sometimes called *ritornello*; 2. A composition for a full orchestra, consisting of from three to six movements. It is for the orchestra what a sonata (q.v.) is for a single instrument; but generally of greater length, and its movements more fully and richly developed, the subjects introduced being worked out in broader masses. The most usual though not unvarying order of movements is a brilliant allegro, ushered in by a slow introduction, an adagio or andante, a minuet with its trio, a short sportive movement called a scherzo, and a lively finale. The symphony is one of the highest of musical compositions, and one in which excellence is rare. Haydn, Mozart, Beethoven, and Mendelssohn are among the few successful composers of symphony; and the nine symphonies of Beethoven are generally acknowledged to be the greatest works of their class. The overture (q.v.) is in form not unlike a symphony, but much shorter; but the terms symphony and overture were at one time used almost synonymously, and several of Haydn's early symphonies are called overtures. At the present day the overture in the composer's score of an Italian opera is called *sinfonia*.

SYMPHYTUM. See COMFREY.

SYMPTOMS (Gr. *sympiptein*, to concur), in medicine, are the morbid phenomena by which the physician becomes aware that derangements of some kind have taken place in the economy; but it requires a mental effort to convert these symptoms into signs of disease. A symptom thus converted into a sign of some special disease or disordered condition, tends to constitute the *diagnosis*, or recognition of the disease. "The interpretation of symptoms," as Dr. Aitken observes, "can only be successful after a close observation of the patient—often prolonged and repeated for more complete investigation—so as to connect the results arrived at with his previous history. The utmost logical acumen is required for the due interpretation of symptoms. The individual value of each ought to be duly weighed; one symptom must be compared with another, and each with all, while the liability to variation of a similar symptom in different cases of a like kind must not be forgotten. Thus only can the nature of a disease be clearly determined, its severity and dangers fully appreciated, its treatment indicated, and the probability of recovery foretold"—*The Science and Practice of Medicine*, 3d ed. vol. i. p. 9. Many

writers, following the example of Laennec, confine the term *symptom* to the phenomena depending on vital properties; while those phenomena of disease which are more directly physical, they call *signs*. We thus have what may be called *physical signs* and *vital symptoms*. The form, size, color, firmness or softness, heat and odor of a part of the body, the sounds which it yields on percussion or disculation, etc., afford *physical signs*; while *vital symptoms* may be exemplified in pain, uneasiness, altered or impaired sensations, spasm, vomiting, the accelerated pulse and hot skin of fever, the state of the tongue and of the alvine and urinary excretions, etc. The term *semiology* (literally, *the theory of signs*) has been given by medical writers to the general study of this subject, which is admirably discussed in Williams's *Principles of Medicine*.

SYNAGOGUE (Gr. = *ecclesia*; Heb. *beth-hakkeneseth*, house of assembly), a Jewish place of worship. The origin of this institution is probably to be traced to the period of the Babylonian captivity, although tradition finds it in the patriarchal times. When, at the time of Ezra, and chiefly through Ezra's instrumentality, the ancient order of things was re-established in Judea, synagogues were established in all the towns for the benefit of those who could not take part oftener than three times a year, or not even as often as that, in the worship of the temple at Jerusalem, and a special ritual of lectures and prayers was instituted. From the time of the Maccabees, we find them even in all the villages; and Josephus, Philo, the New Testament, the Mishna, and the Talmud, constantly allude to them. Common prayer and religious instruction were the purpose for which the people there met. The Sabbaths and feast-days were the principal times on which the faithful assembled in them; and they contributed more than anything else to the steadfast adherence of the people to their religion and liberty as long as there was any possibility of keeping both intact. At the same time they gradually undermined the priestly and aristocratic element that gathered round the temple, its gorgeous worship and kingly revenues. Little is known of any special laws respecting the construction of these buildings, save that the faces of the worshipers should be directed toward Jerusalem (*misrach* = eastward) (see *Mosque*); or that, in accordance with the verse in the Psalms, there should be a slight descent of a step or two on entering it, or that it should stand, if feasible, on a slightly elevated ground, or be somehow or other made visible far off. Erected out of the common funds or free gifts of the community, it had also to be supported by taxes and donations. All profane doings were strictly prohibited in it. No eating, drinking, reckoning, and the like, were allowed; and even as to dress and other things of general decorum, the reverence due to the place was enforced as rigidly as possible. It represented in miniature the form of the temple, itself an enlarged type of the tabernacle. At the extreme eastern end was the *Aron hakodesh*, the holy ark, containing several copies of the Pentateuch, from which the periodical readings were chanted. In front of this was the stand of the public reader of the prayers, not far from which was suspended the everlasting lamp (*ner tamid*). On a raised platform in the middle of the synagogue, was the place of the reader or preacher. The women sat separated from the men by a low partition five or six ft. high. The affairs of the synagogue were administered by a board of "ancients" or "elders," at whose head stood a chief or principal (*Rosh hakkeneseth* = *archisynagogos*). This college managed the inner affairs of the synagogue, and had even the power of excommunication. The officiating minister, whose office it was to recite the prayers aloud, was called *sheliach tzibbur*—messenger of the community (*angelos ecclesias*, Rev.). His qualifications were, among others, to be active, to be father of a family, not to be rich or engaged in business, to possess a good voice, to be apt to teach, etc. The beadle, or *chazzan*, had the general charge of the sacred place, and its books and implements. He had to present the scroll to the reader, and assist on other occasions. During the week-days, he had to teach the children of the town or village. He too had to be initiated by a solemn imposition of hands. This name of *chazzan*, however, at a later period, came to designate the officiating minister, and it has retained that meaning until this day. Almoners or deacons, who collected or distributed the alms, possibly the same as the *batlanim* or "idle men," whose office in relation to the synagogue cannot be exactly determined now, but who had always to be ready for the purpose of making up the requisite number of *ten* worshipers, were further attached to the general body of officials. Respecting the prayers used, we have spoken under **LITURGY (JEWISH)**. As to the time of daily worship, we may observe that the third, sixth, and ninth hours of the day were the times appointed for it, and the more special days were the Monday and Thursday, when the judges sat, and the villagers came to town; and the Saturday, on which the forms of some of the prayers were altered according to the occasion.

On the connection between the Jewish synagogue and the Christian church, and their respective rites and modes of worship we cannot here enlarge. Thus much, however, we may say, that it is obvious to the most superficial observation that the principal practices of the latter belong, with certain modifications, to the former; and it has been conjectured that even the melodies of certain hymns still sung in the Roman churches are to be traced to the temple and the synagogues. It is, moreover, well known that the early Christian churches were entirely organized after the pattern of the synagogues. As to the judicial power exercised by the officers of the synagogue, we refer to **SANHEDRIM**. They had, there can hardly be a doubt, a kind of authority with

regard to religious transgressions ; but how far they were allowed to carry this authority is not so easily determined. Modern synagogues differ but in some minor points—additional prayers and the like—from what we gather to have been the nature of those at the time of Christ, save that there are no more elders, but a simple board elected from the community, without any authority beyond that of, perhaps, a board of church wardens, and that the chazzan, as we said, has now the functions of the “sheliach.” See JEWS, LITURGY (JEWISH), etc. The languages used in the early synagogues of Palestine and Alexandria were Hebrew, Aramaic, and Greek respectively.

SYNAGOGUE, THE GREAT (*keneseth haggedolah*), an assembly or synod, supposed to have been founded and presided over by Ezra, consisting of 120 men, said to have been engaged in remodeling the national and religious institutions of the Jews after the return from Babylon. The palpable chronological discrepancies that occur in the early accounts about this synod, together with other doubtful points, have led modern scholars to deny its existence completely. But the fact of Josephus not mentioning it avails very little against the positive assertions of the Talmud, and what is still more important, of the Karaites, the professed adversaries of all tradition. True, Ezra, the contemporary of Artaxerxes, can never have taken his place in it together with Zerubbabel and Joshua, who left Babylon under Cyrus, or with Simeon the Just, who lived at the time of Alexander the Great. These, however, are but apparent anachronisms. The tradition never meant anything else than that the institution founded by Ezra, and which lasted up to the time of Alexander, comprised 120 men, of whom Simeon was one of the last. Anyhow, there is absolutely no reason to doubt that Ezra and Nehemiah did a certain amount of work which they could not have done without being assisted by eminent collaborators. It was to this body to which certain vital ameliorations in the administration of justice are ascribed. They developed public instruction, and fixed and enlarged the Mosaic laws by certain rules of interpretation. “Be circumspect in judgment; make many disciples; and erect a fence around the law;” are some of the principal sayings ascribed to them. Above all, it seems to have been the office of Ezra and his coadjutors—the men of the Great Synagogue—to collect, purify, and redact the sacred books as much as in them lay. Whether, however, they really introduced the vowel-points, which have been handed down to us by the Masoretes, instituted the Feast of Purim, sanctioned the Eighteen Benedictions (see LITURGY, JEWISH), etc., is more than doubtful. They certainly disappeared before the Sanhedrim (q.v.) were instituted, but it may be that their legislative functions were no longer needed at that advanced period.

SYNANTHEREÆ. See COMPOSITÆ.

SYNCLINAL AXIS is the line of curve in the trough of a series of beds from which the strata rise on either side. The ridge-curve is called the anticlinal axis.

SYNCOPE TION, in music. Notes which begin on the unaccented part of a measure, and end on the accented, are called syncopated or driving notes. Their effect is to invert the rhythm, and lay an emphasis on the usually unaccented part of the measure, e.g.:

SYNCOPE. See FAINTING.

SYNCRETISM (signifying acting together as Cretans), a term used : I. In ancient times, *politically*, to designate the Cretan custom of disregarding all internal dissensions whenever a controversy with a foreign country occurred. II. In the 16th c., *philosophically*, to denote the efforts made to reconcile opposing systems. III. In the 17th c., *theologically*, first by Pereus in his *Irenicon*, and afterward to describe the views of Calixtus and his followers, who sought to heal the schism in the church by making the traditions of the first five centuries of equal authority with the Bible, and by adopting the Apostles' creed as the common basis of all Christian denominations and a sufficient definition of true Christianity. The plan was that all holding these tenets should come into peaceful relations.

SYNDIC (Gr. *syn*, with, and *diké*, justice), a name which has at different times and in different countries been given to various municipal and other officers. In Geneva the chief magistrate was formerly called the syndic. The syndics of cities in France, under the old régime, were officers delegated by the municipality as agents or mandatories; the various trading companies in Paris and the university had also their syndics; and in the university of Cambridge the same name is applied to members of special committees of members of the senate, appointed by grace from time to time for specific duties. See UNIVERSITY.

SYNECDOCHE (Gr. literally an “understanding one thing with another”) is a term in rhetoric denoting that mode of expression by which a part is put for the whole, and *vice versa*; as e.g., a door for a house, a sword for any weapon of war.

SYNERGISM (Gr. *synergeo*, to work together with), the name given to a doctrine of theology which teaches that in the work of conversion, the will of man is not wholly

passive, but can co-operate, through consent, with the Divine Spirit. About 1557 the question was hotly discussed by the Protestant theologians Pfeflinger, Flacius, and Strigel, and soon the whole theological world was wrangling over the point. The Wittenberg divines were in favor of, the Mansfeld divines against, synergism. Finally, the *Concodein formel*, in its third article, condemned it.

SYNE'SIUS, b. Cyrene, Africa, about 379, from a rich and noble family; was a philosopher, poet, and Christian bishop. He was a pupil of the renowned Hypatia of Alexandria, afterward studied at Athens, and, returning to Cyrene, lived in retirement. He was sent to Constantinople to solicit aid for the people suffering from famine, and, soon after his return to Cyrene, was converted from paganism by the influence of his Christian wife. In 410, though not baptized, and married, and holding certain doctrines not considered orthodox, he was made bishop of Ptolemais. After baptism and seven months' preparation he entered upon his duties. His works, mostly epistles, treatises and hymns, were collected by Petavius in Greek, with a Latin translation, and published in 1612 and 1640. The hymns have often been published, in several languages. He is supposed to have died about 415.

SYNGE NESIA. See COMPOSITEÆ.

SYNGNA THIDÆ. See PIPE-FISH.

SYNOD (Gr. and Lat., an assembly) in general signifies a meeting, but it is almost exclusively applied to ecclesiastical assemblies for the purpose of deliberating on doctrinal or disciplinary subjects. In church law, several kinds of synods—called also councils (q.v.)—are enumerated: (1) ecumenical or general, of the entire church; (2) national—that is, of the church of an entire nation; (3) provincial—that is, of a province; (4) diocesan, or of a single diocese. Of these, the ecumenical council has been already described. Of the others, little explanation is needed beyond what is conveyed in the names themselves. By the law of the Roman Catholic church, the decrees of a national or provincial synod must be submitted to the pope, and unless confirmed by him, or at least suffered to pass for two years without condemnation, are not held to have force. The diocesan synod is convened by the bishop, and consists of the members of the chapter, the beneficed clergy having the permanent care of souls, and the heads of the communities of regular clergy. Synods of the English church are only held by the authority of the crown. A Presbyterian synod consists of only the ministers and elders within the particular district, generally one elder for each congregation. It is subordinate, however, to the general assembly, when there is a general assembly.

SYNO DIC, the epithet applied to the period which elapses between a planet's appearance at one of the nodes of its orbit, and its return to the same node. See NODES and MONTH.

SYNONYM. When any one of several words will serve to name or express the same thing, that thing is said to be *polyonymous*, or many-named, and the words are called *synonyms* (Gr. names together, or in company). In this wide sense, *man*, *soldier*, *general*, *Frenchman*, might be called synonyms, as they can all be applied to denote the same individual—e.g., Napoleon. See NOUN. But the term is commonly applied in a restricted sense to words having substantially the same meaning, with only slight shades of difference—as *observe* and *remark*. In a settled and matured language, no two words can have exactly the same meaning; in such a case, one of them would be superfluous, and would be silently dropped. Words that were originally identical in application, have become differentiated by usage, each being appropriated to a special variety of the general notion.

The English language abounds in pairs of synonyms like *sharp* and *acute*, of which the one is Anglo-Saxon, the other borrowed from the Latin. It would be difficult to find a case of more exact correspondence of sense than *acutus* in Latin, and *sharp* (Ger. *scharf*) in Teutonic; but *acute* in English has become confined to the metaphorical sense of sharpness of the intellect or of the senses, the only case of its retaining the primary, physical signification being in the technical phrase, an "acute angle." *Sharp*, again, is applied both in the physical sense and also in the metaphorical; but metaphorical *sharpness* is not exactly the same thing as *acuteness*. A "sharp" lad is one quick in apprehension and movement; an "acute" intellect is one having great power of penetration and discrimination; while in a lawyer of "sharp" practice, a reprehensible moral quality is implied.

SYNOVIAL MEMBRANES and FLUID. In every joint in which a considerable range of motion is required, the osseous segments (or contiguous extremities of bones) are separated by a space, which is called the cavity of the joint. The end of each of the bones entering into the composition of the joint is incrustated by a layer of articular cartilage adapted to its form, and the entire cavity of the joint is lined by a delicate membrane, which is termed the *synovial membrane*, which secretes a peculiar viscid matter, termed *synovia*, or *synovial fluid*, for the purpose of lubricating the inner surface. In its microscopical characters, a synovial membrane so closely resembles a serous membrane, that we shall content ourselves with referring the reader to the article on the latter structures. There are, however, certain points of difference, which are fully described in the article "Serous and Synovial Membranes" in *The Cyclopædia of Anatomy and Physiology*. Like

a serous membrane, a synovial membrane is always a closed bag, like the pleuræ, for example, with an attached and a free surface, the latter being smooth and moist. A very simple form of synovial membrane—anatomically known as a *bursa*—is employed to facilitate the gliding of a tendon of a muscle or of the integument over a projection of bone. It consists of a bag connected by areolar tissue with the neighboring parts, and secreting a fluid in its interior. These bags are sometimes prolonged into *synovial sheaths*, which surround long tendons, such as those of the flexor and extensor muscles of the fingers and toes. In deep-seated whitlow (q.v.), when inflammation extends to one of the sheaths, and gives rise to the formation of adhesions, the motion of the inclosed tendon is destroyed, and a permanently stiff finger is the result.

The *synovial fluid*, or *synovia* derives its name from its resemblance to the white of an egg (Gr. *syn*, with, and *oîn*, an egg). It consists of water holding in solution mucin, albumen, extractive matters, fat, and inorganic salts. The analysis of Frerichs shows that the composition and quality of the synovia vary essentially according as an animal is at rest or leads a wandering life.

SYNTAX (Gr. *taxis*, arrangement, *syn*, together) is the part of grammar that teaches the putting together of words for the expressing of thoughts; in other words, it treats of the construction of sentences. The first step is the analysis of sentences—the study of their anatomy and physiology, as it were (see SENTENCE). This important part of the subject is too often altogether overlooked. A clear perception of the mutual relations of the several members of a sentence makes the usual rules of syntax appear self-evident truths, and in most cases superfluous. Most of these rules fall under the heads of (1) concord and government, and (2) order of words or collocation. For details we must refer to special works on the subject.

SYNTAX, FIGURES OF, are intentional deviations from the ordinary construction of words. The principal figures of syntax will be defined in alphabetical order. **ANAPHORA** is the repetition of the same word or grammatical form at the beginning of several successive clauses, as “*without tumult, without arms, without harm or injury the insurrection was quelled.*” Compare the verses written by Virgil, beginning *Sic vos non vobis*. Cicero (Cat. Or-1. 1) affords a good example of this figure in the repetition of *quid*. **ANASTROPHE** is a form of hyperbaton (q.v.), consisting in a transposition of words, as *rolled the thunder for the thunder rolled*, or “*he travels earth around.*” **ANTIMERIA**, a kind of enallage (q.v.), is the substitution of one part of speech for another, as when Virgil speaks of a “people widely king” instead of a “people ruling widely.” **ASYNDETON** (Gr., *a*, neg., *syndeo*, to bind together) is the ellipsis of a conjunction or connecting particle, as *veni, vidi, vici*, I came, I saw, I conquered. **BRACHYLOGY** (Gr., *brachys*, short, *logos*, discourse) is the use of a concise or pregnant mode of expression. So the Romans would say, “the eye of a horse is bigger than an elephant,” i.e., than (the eye of) an elephant. **CHIASMUS** is a cross-wise arrangement of words, where the words of a second and corresponding set are stated in inverse order to those of the first set, as “*Begot by butchers, but by bishops bred.*” Here, though the two sets of words correspond, they stand in inverse order, the verbs being at the extremes and the prepositional phrases in the centre. If the words should be arranged thus,

by joining the corresponding words the Greek letter X (chi) is

but by bishops bred,
formed, whence the name Chiasmus. **ELLIPSIS** (Gr., omission) is the omission of a word or words necessary for the construction of the sentence, but not essential to its meaning. By means of ellipsis conciseness and impressiveness are gained, and accordingly it prevails in proverbs, as “*More haste, less speed,*” or *Ex pede Her ulem*. Ellipses are used in all languages, though of different forms. *The house we saw*, instead of *the house that we saw* is said to be a form of ellipsis peculiar to English. **ASYNDETON** is a special form of ellipsis. **ENALLAGE** (Gr., change) is the substitution of one part of speech, or of one inflectional form of a word, for another. as “*they fall successive and successive rise.*” Here we have an adjective for the adverb *successively*. In “*surely some disaster has befell,*” we have one inflectional form for another, *befell* for *befallen*. In the hands of a great poet, enallage produces a picturesque effect, as Spenser’s “*My beautifullest bride,*” and Shakespeare’s “*Our sometime sister, now our queen.*” **EPANALEPSIS** (Gr., a taking up again) is a recurrence to the same word or phrase after intervening matter. **EPANASTROPHE** (Gr., a turning back) is the repetition of the end of a clause at the beginning of the next, as “*The mouse ran up the clock, the clock struck one.*” **EPIPHORA** is the repetition of a word or words at the end of successive clauses and hence is the reverse of anaphora (q.v.), as *Lælius navus erat, doctus erat*. **EPIZEUXIS** is the emphatic repetition of a word, as

“*Alone, alone, all, all alone,
Alone on a wide, wide sea.*”

HENDIADYS or **HENDIADYOIN** (Gr., *hen*, one, *dia*, through, *duoin*, two) is the use of two co-ordinate words or phrases instead of an expression, in which one qualifies the other grammatically, or in other words, it is the presentation of *one* idea by means of *two* co-

ordinate words or phrases, as a "couch strewn with *purple and tapestry*," i.e., with purple tapestry or *armis virisque*, with arms and men (i.e. armed men). **HYPPALLAGE** is the use of one case for another, the transference of an epithet from its proper subject to another, as *Tyrrhenus tube clangor* (the Tyrrhenian clang of the trumpet) for *Tyrrhene tube clangor* (the clang of the Tyrrhenian trumpet), compare also *arma dei Volcania* for *arma a deo Volcani facta*. **HYPERBATON** is the transposition of words or clauses. The transposition of words is called *anastrophe* (q.v.). An example of hyperbaton of clauses is *valet atque vivit* (he is well and alive) for *vivit atque valet* (he is alive and well). **HYSTEROLOG** **PROTERON** (Gr. the last first) is an inversion of the natural order or logical sequence of ideas or propositions. This figure is a form of hyperbaton. It is also called **HYSTEROLOGY**. For example, compare Virgil's *moriamur et in arma ruamus* (let us die and rush into arms). Hyperbaton in its several forms is more especially characteristic of poetry than of prose. **PLEONASM** (Gr. *pleon*, more, too much) is the use of superfluous words, sometimes, however, arising from a desire to secure strength, as in the excessive use of the negative in conversation, and especially by uneducated persons, or by children. **POLYSYNDETON** (Gr. *polu*, much, excessively, *syndeo*, to bind together) is pleonasm in the use of conjunctions and is the reverse of *asyndeton*. For the following sentence, "We have ships, and men, and money, and stores," only the last *and* is needed. **PROLEPSIS** (anticipation) consists in introducing a word in advance of its proper place, as "I know *thee* who thou art." Here *thee* anticipates *thou* and is also pleonastic. **PROLEPSIS** also denotes the use of an epithet before it is logically applicable, as *Scuta latentia condunt* (they conceal their hiding (or hidden) shields). Here *latentia* is an example of *prolepsis*, since it anticipates the action of *condunt* and is not strictly applicable until the action of *condunt* has ceased. **SYLLEPSIS** is the agreement of an adjective or verb with only one of two or more subjects with which it is linked, as *rex et regina beati*. **SYNESIS** is a construction of words according to the sense conveyed by them rather than by the strict requirements of grammatical rules, as "Philip went down to Samaria and preached Christ unto them." This meaning is now in English rhetoric included under *Syllepsis*. **TMESIS** (Gr., a cutting) is the separation of the parts of a word, as in Ennius' famous line, "*saxo cere comminuit brum*," or, in "the love of God to us *ward*." **ZEUGMA** is the use of a word in two or more connections, though in strictness, it is applicable to only one of them.

SYNTHESIS (Gr. *Synthēsis*, making a whole out of parts) is a term employed in chemistry to designate the building up of a more or less complicated product from its elementary constituents. As the synthesis of inorganic compounds is usually very simple, we shall confine our remarks to organic compounds. To take a very common substance as an illustration, there is no difficulty in resolving sugar into its elements. An ultimate analysis shows that sugar may be represented by the formula $C_{12}H_{22}O_{11}$, and that any given weight of it contains 144 parts by weight of carbon, 22 of hydrogen, and 176 of oxygen. This pulling to pieces of the sugar is an easy matter, and has been known to chemists for more than half a century; but the putting together of the pieces, or, in other words, the synthesis of sugar, is a much more difficult task. Again, alcohol consists of 24 parts of carbon, 6 of hydrogen, and 16 of oxygen; but no alcohol results from merely making such a mixture. There was a general belief that organic products, such as sugar, alcohol, urea, oxalic acid, taurine, leucine, etc., required for their production a mysterious so-called *vital-force*, totally distinct from the ordinary forces acting on matter. The first blow to this now obsolete doctrine was struck by Wöhler in 1828, when he discovered that *urea* might be artificially obtained. (See ORGANIC COMPOUNDS.) Shortly afterwards Pelouze obtained *formic acid* from inorganic materials, and in 1845 Kolbe effected the synthesis of *acetic acid*, and of its derivatives, *acetone*, *methane*, or *marsh gas*, and *ethane*.

We give a few examples showing the synthesis of some simple organic bodies from the elements. It is, of course, understood that the inorganic reagents used, such as water, H_2O , ammonia, NH_3 , potassium hydrate, KOH , sulphuric acid, H_2SO_4 , may also be prepared from their elements.

First: Carbon burned in oxygen gas produces carbonic acid, CO_2 . This passed over heated potassium forms potassium oxalate, $K_2C_2O_4$ ($2CO_2 + K_2 = K_2C_2O_4$), from which *oxalic acid* may be obtained. Carbonic acid and aqueous vapor passed over heated potassium produce potassium bicarbonate, $KHCO_3$, and potassium formate, $KHCO_2$. From the latter *formic acid*, CH_2O_2 , may be prepared. By subjecting potassium formate to a red heat *formic aldehyde*, CH_2O , and *methyl alcohol*, CH_3OH , are given off. *Formic acid*, *formic aldehyde*, and *methyl alcohol* are the starting-points from which other and higher alcohols, aldehydes, and acids may be built up. Again, carbonic acid reacts with ammonia, producing ammonium carbonate, $NH_4 \cdot CO_2 \cdot NH_3$, which on being heated gives *urea*, $NH_2 \cdot CO \cdot NH_2$; and urea is the source of a long train of organic compounds.

Second: Carbon burned with a limited supply of oxygen produces carbonic oxide, CO . This passed over heated potassium hydrate, KOH , gives potassium formate, $KHCO_2$. Carbonic oxide treated with chlorine in the sunlight gives carbonyl chloride, or phosgene, $COCl_2$, which is a useful synthetical reagent.

If the methyl alcohol, obtained in the preceding paragraph, be treated with metallic sodium, sodium methylate, $CH_3 \cdot O \cdot Na$, is formed. This acted on by carbonic oxide gives sodium acetate, $CH_3 \cdot CO \cdot O \cdot Na$, a source of *acetic acid*, CH_3COOH , or $C_2H_4O_2$.

Third: Carbon heated with potassium hydrate, in presence of nitrogen, gives *potassium cyanide*, KCN , the source of all the cyanides and cyanogen compounds, and from which *hydrocyanic acid*, HCN , is directly prepared. Hydrocyanic acid is also formed by passing a mixture of acetylene, C_2H_2 (see next paragraph), and nitrogen through a red-hot

tube. Hydrocyanic acid may be converted into *formic acid* by the action of aqueous hydrochloric acid, or into *methylamine*, CH_3NH_2 , by reduction with nascent hydrogen. Potassium cyanide on oxidation gives potassium cyanate, KCNO ; from this ammonium cyanate, NH_4CNO , may be prepared. The latter on being heated produces *urea*, $\text{NH}_2\cdot\text{CO}\cdot\text{NH}_2$.

Fourth: The electric arc between carbon points in an atmosphere of hydrogen produces *acetylene*, C_2H_2 . This, mixed with hydrogen and passed through a red-hot tube, gives olefiant gas, or ethylene, C_2H_4 , which, agitated with strong sulphuric acid, produces sulphovinic acid, $\text{C}_2\text{H}_5\text{HSO}_4$. On distilling this acid with water, ordinary ethyl alcohol, $\text{C}_2\text{H}_5\text{OH}$, is formed, and may readily be obtained pure. Ethyl alcohol is the source of chloral, chloroform, acetic acid, etc.

Acetylene alone passed through a red-hot tube gives benzol, C_6H_6 . With this as a starting-point, nitro-benzol, aniline, phenol, naphthalene, anthracene, etc., may be constructed. The ethylene mentioned above can be converted, through several steps, into succinic, malic, or tartaric acid. (See article on CHEMISTRY.)

With the help of the foregoing simple products, an unlimited number of higher and more complex bodies may be built up. The synthesis of such compounds as lactic acid, butyric acid, citric acid, amyl alcohol; the oils of bitter almonds, wintergreen, and cinnamon; glycerine, and most of the fats, presents no great difficulty.

In 1868 Graebe and Liebermann, by starting with anthracene, $\text{C}_{14}\text{H}_{10}$, a hydrocarbon isolated from coal-tar, built up by synthetical processes the substance called alizarin, which occurs naturally in madder root, and which gives the latter its chief value as a dye-stuff. This artificial alizarin is now made on an enormous scale in Germany, and has almost entirely displaced madder in dyeing and calico-printing. In 1880 Adolf Baeyer accomplished the synthesis of indigo. His starting-point was toluol, $\text{C}_6\text{H}_5\text{CH}_3$, a hydrocarbon found in coal-tar. In 1887 Ladenburg succeeded in the synthesis of conine, $\text{C}_8\text{H}_{17}\text{N}$, the poisonous alkaloid found in hemlock. Vanillin, the odoriferous flavoring principle of the vanilla bean, has been made artificially by several chemists. Antipyrin, a new and useful drug, and saccharin, a substance 280 times sweeter than sugar, are entirely the products of synthesis. The beautiful coal-tar colors, erroneously called anilines, such as fuchsin or magenta, methyl, violet, mauve, eosin, safranin, rosolic acid, etc., furnish admirable illustrations of the constructive powers of organic chemistry. These are all examples of the application of synthesis to the useful arts. For further information on this subject, the reader is referred to Roscoe and Schorlemmer's *Treatise on Chemistry* (1881), Vol. III.; to Berthelot's *Leçons sur les Methodes Générales de Synthèse en Chimie Organique*; or to Miller's *Elements of Chemistry*.

We cannot conclude without adverting briefly to the possibility of economically replacing natural processes by artificial ones in the formation of organic compounds. On this subject, one of our most distinguished organic chemists, Dr. Frankland, observes that "at present, the possibility of doing this only attains to probability in the case of rare and exceptional products of animal and vegetable life. By no processes at present known could we produce sugar, glycerine, or alcohol from their elements at one hundred times their present cost, as obtained through the agency of vitality. But although our present prospects of rivaling vital processes in the economic production of staple organic compounds, such as those constituting the food of man, are exceedingly slight, yet it would be rash to pronounce their ultimate realization impossible. It must be remembered that this branch of chemistry is as yet in its merest infancy; that it has hitherto attracted the attention of but few minds; and further, that many analogous substitutes of artificial for natural processes have been achieved."

SYNTONIN, or MUSCLE FIBRINE (Gr. *synteinein*, to render tense), contains in 100 parts: carbon, 54.06; hydrogen, 7.28; nitrogen, 16.05; oxygen, 21.50; and sulphur, 1.11. It is the principal constituent and the essential basis of all the contractile tissues. It may be obtained from muscular fibrin in the form of a coherent, elastic, snow-white mass; but whether it exists in the living body in a solid form or in solution, is undecided. Many recent physiological writers hold the latter view, and maintain that the phenomenon of cadaveric rigidity (*rigor mortis*) is due to its spontaneously coagulating after death.

SYPHAX, b. about 250 B.C.; d. 201; a Numidian prince, who was incited by the Romans to war against Carthage; was twice defeated by Masinissa (q.v.), but at last recovered his throne. Scipio thereupon sought an alliance with Syphax, and to prevent this, Hasdrubal gave his daughter Sophonisba to Syphax in marriage, and not long after Syphax, aided by the Carthaginians, drove Masinissa from his kingdom. Again forming an alliance with Carthage, Syphax, on the landing of Scipio in Africa, B.C. 203, raised a large army which was nearly destroyed by Scipio; two other armies met with the same fate and Syphax was taken prisoner.

SYPHILIS is, according to Dr. Farr's system of nosological classification, to be regarded as belonging to the ethnetic order of zymotic diseases (see NOSOLOGY and ZYMOTIC DISEASES). These diseases have the common property of being developed in the system after the introduction by inoculation or implantation of specific poisons. The poisons which produce diseases of this order may be introduced through any abraded cutaneous surface, or through mucous membranes, especially if any solution of continuity occurs. A morbid poison thus introduced into the system produces a specific effect both on the tissue at the place of insertion and on the blood, as soon as the poison

begins to be become absorbed; or, in other words, it produces both a constitutional and a local change. The absorbed virus seems to undergo the following changes in the living and infected body—viz. (1) Increase, (2) Transformation, and (3) Separation or excretion. Taking our illustrations from the disease to which this article is specially devoted, the *increase* is shown by the fact, that the pus from a single syphilitic sore may by inoculation be made to spread the disease a thousand-fold. The *transformation* is indicated by the successive phenomena which supervene during the course of the disease. For example, syphilis is followed, as we shall presently show, by a series of secondary and tertiary phenomena, which follow a tolerably uniform course in different patients. The *separation or excretion* of the poison may be accomplished in several ways. While in some of the more intense poisons—such as those of certain serpents—the whole mass of the blood seems rapidly affected, in others, as syphilis, “a double process of the zymotic-like action seems to take place before the full effects which the poison is capable of producing are completed. The multiplication of the venereal poison, and its effects upon the system, seem to become developed during the existence of the hardening process which surrounds the infecting venereal sore. This is the first zymotic-like process, and is attended with a local papule, and perhaps an ulcer. From this local sore the system becomes contaminated, and in the blood a second process (of zymosis?) appears to be completed, by which the original poison becomes intensified, its pernicious influence more complete, and its specific, secondary, and tertiary effects are more fully developed.”—Aitken's *Science and Practice of Medicine*, 3d ed., vol. i. p. 666.

From this brief sketch of the nature of enthetic diseases, we turn to the consideration of the special disorder known as *syphilis*—a word whose origin is unknown. The terrible ravages of this disease among our soldiers and sailors, to say nothing of the fearful misery which it occasions in private life, afford more than sufficient apology for our introducing into these pages some of the most important details regarding this repulsive form of disease.* It is almost unnecessary to observe that syphilis is a contagious disease usually propagated by impure sexual intercourse. The following is a brief history of the course of the disease, if its progress is not checked by proper remedial agents. At an uncertain period, varying from three to ten days, after exposure to the infection, one or more venereal ulcers (commonly known as *chancres*) appear upon the generative organs. These ulcers present many varieties, which have been variously classified. The following arrangement, by Mr. Henry Lee, surgeon to the Lock hospital, is an eminently practical one—viz. (1) The Hunterian or indurated or infecting chancre; (2) The non-indurated or suppurative chancre; (3) The ulcerative chancre; and (4) The sloughing chancre. These local affections are so different in their characters, and in their action on the constitution, that each must have a brief separate notice. (1) The *indurated*, or, as it is frequently termed, the *Hunterian chancre*, from its having been first accurately described by John Hunter, is the only one of these local affections that can be associated with constitutional syphilis. Its natural course is thus described by Mr. Lee. “At an uncertain period, but generally from three to four days after exposure to infection, attention may be drawn to the part by a slight itching. On examination, a red spot, surrounded by a little induration, will perhaps present itself, or a vesicle about the size of a millet-seed will not unfrequently form upon the infected part. The cuticle covering this vesicle is so thin that it usually gives way at a very early period; and this commonly happens before the disease has been carefully examined. The base of the vesicle then becomes indurated, and the induration (whether preceded or accompanied by a pimple or a vesicle, or independent of either of these) assumes a circular form, extending equally in every direction, and terminating quite abruptly in apparently healthy parts. A sore generally follows; this is excavated, without granulations, sometimes glazed, at other times having some adhesive matter on its surface. The color of the chancre will depend often upon the amount and character of the substance which adheres to it, and will frequently present a fawn hue, or different shades of brown and red. When this adventitious matter is removed, the sore will usually again assume its original smooth and red glazed appearance.”—“Syphilis” in Holmes's *System of Surgery*, vol. i. p. 400. This variety of sore frequently gives rise to a chronic enlargement of one of the glands of the groin (forming what is termed a *bubo*), which does not involve the skin or the cellular membrane. It is followed by certain

* Dr. Aitken observes that “no statistical nosology gives any idea of the number of men lost to the public service from syphilis. The loss of strength from venereal diseases alone (gonorrhea being included with syphilis in this term, and forming about 40 per cent of the cases) is equal to the loss of more than eight days annually of every soldier in the service.” Dr. Balfour in his *Medical, Sanitary, and Statistical Report of the Army Medical Department* for 1860, relates that “more than one-third of all the admissions into hospital have been on account of venereal diseases (369 per 1000), and the average number constantly in hospital is equal to 23.69 per 1000 of strength (2,315 men), each remaining in hospital on an average 23½ days. Thus the inefficiency is constantly equal to about 2½ regiments.” In 1861, these diseases caused a loss equal to 8.69 days for every soldier serving at home, there being a daily inefficiency of 2,077 men; and the numbers are nearly the same for the succeeding years. The daily loss of service in the navy, in 1862, was about that of 586 men per day. How far these data apply to our civil population, it is hard to say; but it is much to be feared they apply pretty closely. “It is a question,” says Dr. Parkes, “whether a large majority of the young men of the upper and middle class do not suffer in youth from some form of venereal disease. In the lower classes, it is perhaps equally common.”—*Practical Hygiene*, p. 453. For a comparison between the amount of venereal disease in various European armies, the reader may consult the same work, pp. 502, 503.

constitutional symptoms known as *secondary symptoms*, and requires, both in its primary and secondary forms, mercurial treatment. (2) The *suppurating chancre* usually begins as an abrasion, which when fully developed, often presents the same appearance as if a piece of skin had been removed by a circular punch. The sore is covered with ill formed granulations, and extending equally in all directions, maintains its circular form. After continuing three or four weeks, it generally heals, without leaving the hardness which is so characteristic of the Hunterian, infecting or indurated sore. Another important diagnostic difference is furnished by the microscopico-chemical examination of the fluid secreted by the sore. In this suppurating sore the secretion consists of pus, which, on the addition of acetic acid, exhibits the characteristic compound nuclei; while in the infecting sore the secretion resembles turbid serum, presenting none of the characters of the pus. It does not give rise to bubo, nor is it followed by secondary symptoms. (3) The *ulcerative chancre* is a ragged worm-eaten ulceration; secreting an ill-formed pus, and presenting an irritable surface. Soon after the appearance of this sore, one of the glands of the groin will become enlarged and painful. This may be preceded by a shivering fit, more or less marked. The enlarged gland or bubo becomes very tender to pressure, and as the swelling increases, the skin becomes red, especially at the center, and the general symptoms of suppuration present themselves. Great relief is afforded by the discharge of the pus. It is never followed by secondary symptoms, and, like the preceding form, requires only local treatment. (4) The *sloughing chancre* is fortunately rare in this country, but in many foreign ports, in warm and hot countries, this form of syphilis commits great ravages among our sailors, who have given to it certain characteristic names, such as the *black pox*, the *black lion*, etc. It does not affect the inguinal glands, and is not followed by constitutional symptoms, and requires only local treatment.

Before noticing the constitutional or secondary symptoms which follow the Hunterian or infecting sore, we shall very briefly describe the treatment required for the last three forms, in which no constitutional symptoms occur. A suppurating sore should at once be thoroughly cauterized, so as to destroy all the tissues which have imbibed the poison. To secure this result, strong caustics are desirable; and as they sometimes extend further than is desired, an antidote should be at hand, which not only checks the further extension of the caustic, but deadens the pain. The agents most used in these cases are caustics and the mineral acids, and the *potassa cum calce*, a combination of potash and lime, which is prepared in the form of small rods for this purpose. The last of these is on the whole the best, as the extent to which it acts may be accurately regulated. When the action is sufficient, the application of a dilute acid will relieve the pain. Nitrate of silver, which is often employed, is not sufficiently energetic in its action to eradicate the disease. In the ulcerative sore, which is often irritable and painful, opium is useful both locally and internally. In other respects, the same treatment must be adopted as in the preceding variety. As the various means that have been suggested for preventing the suppuration of the bubo, which always accompanies this sore, are of no avail, it is useless to mention them. If, after the bubo has burst, the remains of an indolent, enlarged gland, incapable of forming healthy granulations, are left, caustic must be applied, so as to cause them to slough away. In sloughing sores, the great object is to check the destructive process; for which purpose, fomentations and poultices are applied locally, and large and repeated doses of opium are given internally. The nitric acid lotion, or a solution of potassio-tartrate of iron (10 grains to an ounce of water), is often an efficient local application in these cases.

We now return to the consideration of the Hunterian or indurated chancre, the only variety of venereal sore that gives rise to secondary or constitutional symptoms. If the patient seeks medical assistance as soon as he perceives the sore, it is possible that the application of a caustic will destroy the poison, and prevent any constitutional symptoms. If, however, four days or more elapse before treatment commences, the best local application is some form of mercury, as mercurial ointment spread on lint, or the application of black wash (see LORIONS) steeped in the same material. When the poison has once entered the circulation, and become diffused throughout the body, it is desirable to neutralize it, if possible, before the appearance of any secondary symptoms. A very large number of drugs have at different times possessed an anti-syphilitic reputation, and a few are doubtless useful; as, for example, iodide of potassium. "There is one medicine alone," says Mr. Henry Lee, one of the highest British authorities on the subject, "which, through good report and evil report, in spite of the strongest prejudices of some against its use, and the no less adverse influence of others, who have employed it to an unjustifiable extent, has maintained its general reputation."—*Op. cit.*, p. 418. In these remarks on the value of mercury (if judiciously given) we fully concur; but the mercurialists and non-mercurialists are almost equally divided. It may be given internally in pills or in solution; or it may be introduced into the system through the skin, in the form of ointment; or lastly, it may be employed in the form of vapor, and thus applied to the skin. Of these three methods, none is equal to mercurial fumigation by calomel vapor, either in the readiness with which it removes the symptoms, or the slight disturbance it excites in the constitution, or in its certainty in preventing relapse. This process is a very simple one. A piece of brick must be heated to a dull red heat, and placed in a pan having a little water at the bottom. A quantity of calo-

mel, varying from 10 to 20 grains, is placed on the top of the brick; and the patient then sits over the pan in a cane-bottomed chair, enveloped from his neck downward in a large blanket.* The operation is best performed at bedtime; it is complete in a quarter of an hour; and when the patient is sufficiently cool to put on his night-shirt, he should go to bed without disturbing the calomel on the surface of the skin. It is almost impossible to produce salivation by this means of administering mercury; and all that is requisite is to produce a slight tenderness of the gums. The system must be kept under this gentle influence of the mercury till the induration in the primary sore has disappeared. At a period usually varying from one to two months after the first appearance of the induration (which is regarded by some writers as the first of the secondary symptoms), slight febrile symptoms, usually followed by an exanthematous eruption of the skin, often accompanied by sore throat, will occur. This eruption is a variety of *roseola*; it is of a rose-red color, which disappears on pressure, and is not raised above the surface. It generally disappears in a few days, but if it persist, it will gradually change to a copper color, which is characteristic of all syphilitic eruptions which remain for a considerable time without suppurating or ulcerating. The syphilitic eruptions which usually follow this primary rash may assume the varied forms of lichen, syphilitic tubercle, lepra, and psoriasis; and the best mode of treating them is by applying local mercurial fumigation, and at the same time giving iodide of potassium (in five-grain doses thrice a day) internally. Occasionally, in persons with impaired constitutions, syphilitic eruptions assume a pustular character. For a description of these eruptions, we must refer to Cazenave's *Manual of Diseases of the Skin*, translated by Burgess. Similarly, there are cases in which, from some constitutional peculiarity, or, as Mr. Lee suggests, from some want of power in carrying out the natural processes of the disease, the syphilitic eruption may be accompanied by an effusion of serum only; or, in other words, may be of the vesicular type. Thus, we hear of syphilitic herpes, syphilitic eczema, etc. These forms must be treated as the others.

Among the secondary syphilitic diseases of the mucous membrane, may be especially noticed (1) mucous tubercles, (2) deep ulcer of the tonsils, and (3) syphilitic laryngitis. *Mucous tubercles* appear as small tense eminences inside the cheeks, on the arches of the palate, on the lips, on the generative organs, and on the rectum. A solution of corrosive sublimate applied locally (one or two grains to the ounce of water), or calomel, proves an effective local application. *Deep ulcer of the tonsils* is best treated by corrosive sublimate given internally, in doses of $\frac{1}{12}$ of a grain three times a day, in compound tincture of bark and water; and also used as gargle (in the proportion of 2 grains to a mixture of 7 ounces of water and 1 of honey). *Syphilitic ulceration of the larynx*, commonly known as *syphilitic laryngitis*, is characterized by pain or tenderness in the region of the thyroid cartilage (see LARYNX), huskiness of the voice, a hacking cough from attempts to expectorate, with occasional expulsion of purulent matter mixed with blood. If the disease is not checked, enervation, night-sweats, and dangerous exhaustion, ensue, and life is often terminated by suffocation.

In noticing the secondary symptoms, *syphilitic iritis* must not be overlooked; its symptoms and treatment are described in the article IRRIS.

Our limited space precludes more than a very brief allusion to the more important tertiary syphilitic affections. The most important of these are those which attack the bones and their coverings. They may be included under the heads of acute and chronic periostitis (the latter being very common), nodes and exostosis, inflammation of bone, caries, and necrosis; next to these are tertiary affections of the skin and mucous membrane, which consist mainly of intractable ulcerations attacking the face (especially the nose and lips), nails, ears, and mucous membranes of the various openings of the body; and diseases of the glands. In many of these cases a modified form of mercurial fumigation is most useful; but if mercury, even in this form, is thought inexpedient, in consequence of the general debility of the system, iodide of potassium, combined with any of the preparations of sarsaparilla, may be employed. Bark, iron, and the mineral acids are also of service in restoring the strength; and opium, by relieving the nocturnal pains which are so frequently present, will also prove most useful. The reader who wishes to pursue this subject further may be referred to Aitken's *Science and Practice of Medicine*, in which he will find an account of the tertiary syphilitic affections of the nails, heart, brain, lungs, liver, and tongue.

THE SYPHILIS OF CHILDREN is a subject which must not be omitted in an article on this disease. If the constitution of either the father or mother of an infant is saturated with the syphilitic poison, the child may be born with certain symptoms indicating that it is suffering from *congenital syphilis*. Moreover, the child of a mother having a primary sore, but no constitutional symptoms, may be inoculated with syphilis during the act of delivery; or the disease may be communicated in vaccination (if the matter be derived from an impure source); or by contact with syphilitic sores on the persons of wet-nurses or others. All these cases are included in the *infantile* variety of the disease. One of the most striking symptoms of true congenital syphilis is that which is popularly known

* A simple apparatus for mercurial fumigation, consisting of a kind of tin case containing a spirit-lamp, may be procured from dealers in medical and surgical apparatus, by those who object to rough bricks and coarse pans. A special fumigating cloak, in place of the blanket, is sold with the apparatus.

as the *snuffles*, in which a discharge collects in the nose, and sometimes blocks it up so completely that the infant is unable to suck for any length of time. The skin presents an eruption of spots, which are usually somewhat coppery, but sometimes of a rose-red tint; while on the soles of the feet and the palms of the hands the cuticle scales off, and an appearance like that of psoriasis is presented; and flat mucous tubercles occur at the parts where the skin and mucous membrane merge into one another. White ulcers of a crescentic form often occur in the mouth; and with these symptoms there is nearly always observed "the wizened and shrunken look, the anxious expression, and the dirty hue of the skin (a kind of dirty greenish yellow), which imparts to the infant a peculiarly repulsive aspect of old age."—Holmes, "On the Surgical Diseases of Childhood;" *op. cit.*, vol. iv. p. 830. Congenital syphilis frequently causes the death of the fetus at about the fourth or fifth month; and if a woman is repeatedly delivered of dead children from the fourth to the seventh month, the practitioner may fairly conclude that a syphilitic taint is *probably* present. In other cases the child is born alive with the "snuffing" and eruption; but, in the majority of cases, the infant when born is apparently healthy, and the disease does not show itself till about six weeks after birth.

When congenital syphilis is diagnosed with certainty the medical attendant has a very important duty to perform, from which he must not shrink from any feelings of delicacy. He must discover which of the parents is affected, and must prohibit further cohabitation until the secondary symptoms have been completely removed by the treatment which has already been described. "Neglect of this precaution," says Mr. Holmes, in his excellent memoir on congenital syphilis (contained in the 4th vol. of his *System of Surgery*), "may not only entail on the couple the misery of a family of deformed, puny, and ailing children, but to the woman at least is fraught with grave personal danger. Whatever may be the case among the poor, there is no doubt that, in the better classes, congenital syphilis is usually derived from the father, the mother being unaffected except through the fetus." There is scarcely a doubt that a woman carrying a syphilitic fetus may become thus infected with secondary syphilis by the exchange of fetal and maternal blood in the placenta; and this explains how it is that women who have never had the primary infecting sore occasionally show all the symptoms of secondary syphilis after living for some years with husbands similarly affected.

Allusion has already been made to the fact that *infantile* (not *congenital*) syphilis may be communicated by vaccination. There is undoubted evidence that in the year 1861, in a thinly populated district of Piedmont, in which syphilis is virtually unknown, 46 children of various ages were simultaneously attacked with syphilis proceeding from chancres in the arm, and followed by buboes (enlarged glands) in the armpits; and that all these children had been vaccinated directly or indirectly from a single child, who was subsequently proved to have contracted syphilis from a wet-nurse; and further, that these children transmitted the same disease to a number of women, their wet-nurses, mothers, etc., and even to children who nursed and played with them; that the women so infected communicated the disease to their husbands; and finally, that the disease yielded in all cases to the ordinary treatment adopted in syphilis. This, as Mr. Holmes observes, is by far the most convincing instance of the propagation of syphilis by vaccination; but several others are recorded by Mr. Lee (*Lectures on Syphilitic Inoculation*, 1863) and other writers.

Cases in which the nipple of the wet-nurse has been infected by a syphilitic infant are by no means rare, and have in various instances given rise to litigation.

Congenital syphilis and infantile syphilis generally must be treated with mercury—either in the form of inunction, by keeping a flannel band, smeared twice a day with mercurial ointment, in constant contact with the thigh or arm for about six weeks; or internally, by the careful use of gray powder (*hydrarg. c. cretâ*), in doses of a grain and half or two grains, twice a day; combined with a little compound chalk-powder, if any irritation of the bowels occurs. The snuffles will be relieved by syringing the nostrils with lukewarm water, and then introducing a couple of drops of almond or olive oil.

In a foot-note to an early paragraph of this article, we gave abundant evidence of the appalling prevalence of this disease. In his valuable treatise on *Practical Hygiene*, Dr. Parkes discusses the question of the prevention of this disease among soldiers; as, however, his remarks for the most part are applicable to other classes, we shall briefly notice them. The means of prevention which he discusses are: 1. *Continence*, which is promoted by (a) the cultivation of a religious feeling and of pure thought and conversation; (b) the removal from temptation and occasions to sin; (c) constant and agreeable employment, bodily and mentally; and (d) temperance. 2. *Early marriage*.—At present only 6 per cent. of the soldiers are allowed to marry. 3. *Precautions after the risk of contagion*.—In some French towns the use of lotions and washing is vigorously enforced, with the effect of lessening disease considerably. 4. *Cure of the disease in those affected by it*.—Health-inspections, in special reference to venereal diseases, are made weekly in the army by the surgeon or assistant-surgeon. But although similar inspections of all recognized prostitutes have long been made by legal authority in many parts of the continent, no attempt at legal interference with the disease in women was made in Great Britain till 1864, when the "contagious diseases bill" was passed, by which, in the neighborhood of certain places (Portsmouth, Plymouth, Woolwich, Chatham, Sheerness, and Aldershot), prostitutes who were found diseased might be taken to an hospital, and

there detained till cured. A committee appointed a few years ago by government to report upon the best means of checking the disease in the English army, in Feb., 1866, issued their recommendations; the most important of which are—(1) the periodic inspection of all known prostitutes in the garrison towns placed under the provisions of the act of 1864; (2) the appointment of a surgeon vested with the necessary powers; (3) punishment for infringement of the act; (4) the extension of its operation to all garrison and seaport towns used by troops or ships; (5) the prohibition of the residence of public women in beer-shops; (6) that the Lock hospitals be placed under government control, and lastly, that the police supervision of the women in the streets of such towns be more stringent. The evidence taken by this committee seemed to prove that the working of the act of 1864 was decidedly useful. (A contrary report was issued, 1882.) For an account of the various plans which are adopted on the continent for the prevention of this disease—such as the registration of brothels and of prostitutes, and the enforcement of periodic examinations at short intervals—the reader is referred to the various works of Parent-Duchatelet, Acton, Sanger, and others on prostitution; to Lancereaux's *Traité sur S.*; to Lee's *Lectures*; and to two articles by Dr. Holland (of Cork) in the *British and Foreign Medico-Chirurgical Review* for 1852. See PROSTITUTION.

Without entering into any prolonged details regarding the history of this disease, we may briefly mention that, toward the close of the 15th c., a great epidemic of syphilis pervaded Europe, and that it was supposed to have been imported from the new world; and that, in the 16th c., syphilis was recognized as the result of a specific virus. During last century the history of this disease is divisible into three distinct periods, in each of which very different views have been prevalent. These may be described as—1. *The period and doctrine of Hunter*, who believed that the various forms of syphilis and gonorrhea depend upon one and the same poison—a view taught by Carmichael in Dublin, Cazenave in Paris, and others. 2. *The period and doctrine of Ricord*, who proved that gonorrhea was quite different from syphilis, and that inoculation with gonorrheal matter will not cause a chancre; and that there are two classes of chancres, the *soft* and *hard*, originating from the same source. 3. *The present period*, commencing in 1856, in which it is held that, exclusive of gonorrhea, there are two forms of the syphilitic poison. It has been judiciously advised by Mr. Longmore, the professor of military surgery in the army medical school, that in accordance with our present knowledge of this disease, the term *syphilis* or *syphilitic* should be restricted to such cases as are believed to be of a specific infecting kind, while the term *local venereal sore* or *venereal ulceration* should be applied to those cases which require merely local treatment, and are not followed by constitutional symptoms.

SYPHILIZATION is the term used to designate an operation which has the double object of eradicating syphilis already existing in the system, and of securing permanent immunity from any future attacks, by means of repeated inoculations of syphilitic poison. As long ago as the year 1844, a French physician, Auzias Turenne, undertook a number of experiments, with the view of testing whether John Hunter's view, that syphilis could not be communicated to the lower animals, was correct. After some failures he succeeded in producing venereal sores (chancres) in monkeys by inoculating them with the human virus; and he found that rabbits, cats, and horses might be similarly infected from the chancres of the monkey. He likewise found that the chancres produced by inoculation became less and less in each animal, until a period at length arrived at which the poison seemed to have lost all its power, and no further sores could be produced; and he was thus led to believe that by prolonged inoculation the system became protected. The subject was next taken up by Sperino of Turin, who inoculated patients suffering from syphilis by virus from a chancre, and repeated the inoculation once or twice a week, till the poison—as in the case of Turenne's animals—ceased to produce any effect; and when this point was reached, all the other sores had healed. In 1851 Prof. Boeck of Christiania, when traveling through Italy, had his attention drawn to the doctrine of syphilization; and from that time to the present, he has devoted himself unremittingly to it, and is now the great authority on the subject. In 1858 Boeck, in consequence of the results he had attained from the practice of syphilization in cases where no mercurial treatment had been prescribed, alleged that syphilization might in such cases be regarded as a complete and certain cure. In cases where mercurialization has been practiced, the use of iodine has to be persisted in during syphilization. During the summer of 1865 Dr. Boeck visited London, and took active steps to make his views on this subject accurately known in this country, and the surgeons of the Lock Hospital submitted a series of cases to his mode of treatment; and Mr. James Lane, one of the surgeons to that institution, asserted in 1866 that "hitherto, as far as he had seen, it had effected everything which had been promised for it. The progress of the cases in the Lock Hospital had in almost every detail corresponded to the predictions of Prof. Boeck respecting them. In several of those who had been longest under treatment, immunity from inoculation with primary syphilitic matter had been arrived at." The progress of syphilization as a remedy for syphilis and as a proof against syphilitic infection, has not been well marked in this country. Most surgeons are agreed as to the correctness of Prof. Boeck's views, but the practice itself is offensive, and the length of time necessary for its being effectively carried out forms

an objection to its practice. In Sperino's experiments, the treatment extended from 9 to 20 months or more. The practice has been much in vogue in Christiania under Boeck and his colleague M. Bidekap; but it is unlikely to command attention other than of scientific kind, and as tending to acquaint us with the history of syphilis and with the nature of syphilitic infection.

SYRA (anc. *Syros*), the most important, though not the largest member of that group of islands in the Ægean sea known as the Cyclades (see GREECE), lies 13 m. s. of Andros. It is about 10 m. long by 5 broad, bare, hilly, and not very fertile. The products are wine, tobacco, grain, citrons, figs, honey, and vegetables; but the greater portion even of the common necessities of life have to be imported from Greece and foreign countries. Its prosperity is of quite modern growth. During the war of independence, Syra remained neutral, and, in consequence, numerous fugitives flocked thither from other parts of Greece, especially from Chios and Psara, who, besides adding largely to the population, brought with them a spirit of political activity and commercial enterprise, the beneficial effects of which are now strikingly visible. Area, 44 sq. m. The capital *Syra*, or *Hermopolis*, is situated on a bay on the e. side of the island. It rises terrace-wise from the shore, is well built, and is the seat of government for the Cyclades, and the residence of foreign consuls. It has numerous educational institutions. Syra has become the great commercial entrepôt of the Ægean. Nearly one-half of all the imports of Greece reach it through this port. It builds more ships than any other town in the Levant, and owns one-third of all the Greek merchantmen. It has likewise regular steam communication with all the principal trading towns in the Levant. Pop. of the town of Syra, '90, 22,104.

Ancient notices of Syra are scanty. Homer praises it in the *Odyssey* as "rich in pastures, in herds, in wine, in wheat;" but it has no history.

SYRACUSE, anciently the most famous and powerful city of Sicily, situated on the south-eastern coast of the island, 33 m. s.s.e. of Catania, was founded by a body of Corinthian settlers under Archias, one of the Bacchiadæ, 734 B.C. The original colonists seem at first to have occupied nothing more than the little isle of Ortygia, about 1 m. long, and half a mile broad, which lies near the shore. It rapidly rose to prosperity, and was enabled to establish sub-colonies of its own: Acraë (664 B.C.), Casmenæ (644 B.C.), and Camarina (599 B.C.). Nothing definite is known of the early political state of Syra; but before 486 the political power had passed into the hands of a few leading families, or perhaps *clans*, who constituted an oligarchy, while the great body of the citizens formed a malcontent democracy. In that year a revolution took place. The oligarchic families—*Geomori* or *Gamori*, "landowners;" probably the descendants of the original colonists, like the patrician *gentes* of Rome—were expelled, and the sovereign power was transferred to the citizens at large. Before a year passed, however, Gelon (q.v.), "despot" of Gela, had restored the exiles, and at the same time made himself master of Syracuse. He was a great ruler, and under him the city increased in size and wealth. It is believed to have been in Gelon's time that the adjoining mainland was first built upon. The locality of the new settlers was the slopes and heights of Achradina, or the "outer city," a triangular table-land n. of the island of Ortygia, and subsequently connected with it by a mole. It ultimately became the most extensive and populous quarter of Syracuse—contained the agora, a temple of Zeus Olympios, the Prytaneum, with a splendid statue of Sappho, the fine monuments to Timoleon and the elder Dionysius (q.v.), etc. It may be convenient to mention here the other two quarters of the city, especially as the date of their settlement is not known. These were Tyche—so called, according to Cicero, from an ancient temple of "fortune" erected there—occupying a plateau to the w. of Achradina; and Neapolis (new city), stretching along the southern slopes of the plateau, and overlooking the marshes of the Anapus and the "great harbor," a spacious and well sheltered bay, about 5 m. in circumference. Neapolis became one of the finest parts of Syracuse. Here were situated the theater, amphitheater, and numerous temples, of which hardly a relic remains, except of the first mentioned. Ortygia contained the castle or citadel which immediately fronted the mainland, and overlooked the docks or *navalia* in the "lesser harbor."

Reverting to the history of Syracuse, which we must touch upon only in the most cursory manner, a noticeable characteristic of the reign of Hiero (q.v.), the successor of Gelon, is his cultivation of the fine arts, and his liberal patronage of men of genius, as Æschylus, Pindar, etc. In 466 B.C., the democracy again got the upper hand—Thrasylbulus, a "tyrant" of the baser sort, being expelled; and for sixty years a free and popular government was enjoyed, under which Syracuse flourished more than it had ever done. During this period occurred its great struggle with Athens (415–14 B.C.), in which it came off victorious, and its renown at once spread over the whole Greek world. But a new power appeared on the stage—the Carthaginian, whose conquests in Sicily, toward the close of the 5th c., threatened the supremacy of Syracuse. Meanwhile, Dionysius (q.v.) restored the "tyranny" of Gelon, and during a reign of 38 years greatly increased the strength and importance of the city. It was he who constructed the docks in the greater and lesser harbors, and surrounded the city with fortifications. His fierce and victorious war with Carthage (397 B.C.) raised the renown of Syracuse still higher. The reigns of the younger Dionysius (q.v.) and of Dion were unsettled; but

after the restoration of public liberty by Timoleon (344 B.C.), a brief season of tranquillity ensued, during which the prosperity of the city rapidly revived. Under Agathocles, however, the despotic form of government was again established (317 B.C.), and continued, with scarcely an interruption, down to the conquest of the city by the Romans (212 B.C.) during the Hannibalic war—the ruler of Syracuse, Hieronymus, a rash and vain young man, having abandoned the prudent policy of his grandfather, Hiero (q.v.), broken the alliance with Rome, and joined the Carthaginians.

Under the Romans, Syracuse slowly but surely declined, though it always continued to be the capital and first city of Sicily. Captured, pillaged, and burned by the Saracens (878 A.D.), it sunk into complete decay, and is at present confined to its original limits, Ortigia, which, however, is no longer an island, but a peninsula. Pop. '95, commune, 25,300. The streets of the modern town are, with few exceptions, narrow and dirty. Syracuse has a cathedral, a museum of classical antiquities discovered in Syracuse and the neighborhood, a public library, with some curious MSS., numerous churches, monasteries, and nunneries, and carries on a trade chiefly in wine, oil, salt, and salt fish.

SYRACUSE, a province in e. Sicily, on the coast; drained by the Abisso, Anapo, and Ragusa rivers; 1442 sq. m.; pop. '91, 395,797. The surface is mountainous except in the south. Along the sea-coast and in the river valleys the soil is fertile, and adapted to pasturage. Agates and marbles are found. Capital, Syracuse.

SYRACUSE, city and co. seat of Onondaga co., N. Y.; on Onondaga lake, the Erie and Oswego canals, and the Delaware, Lackawanna, and Western, the New York Central and Hudson River, the Rome, Watertown, and Ogdensburg, the West Shore, and several local railroads; about midway between Albany and Buffalo. The site belonged to the Onondaga Indians, and was visited by Jesuit missionaries as early as 1654. By treaties in 1778 and 1795, the state bought from the Indians the tract containing the salt springs, and constituted it the Onondaga Salt Springs reservation. Subsequently portions of the tract were sold to individuals. The present city is a consolidation of the former villages of Salina, Syracuse, Geddes, and Danforth, effected in 1887; with an enlargement of limits authorized by the legislature in 1892. It is known as the "Central city" from its geographical location in the state, and as "Salina city" from its salt interests; and is more widely known as the seat of Syracuse university (q.v.). Among the noteworthy buildings and institutions are the U. S. government building; state hospital for feeble-minded children; co. court-house; city hall; Syracuse athletic club; St. Joseph's, city, women's, and Catholic maternity hospitals; house of the Good Shepherd; house of Providence for Catholic boys; St. Vincent's orphan asylum; Jewish orphan asylum; German asylum; Franciscan convent; Sacred Heart academy for boys and girls; St. John's academy for Catholic boys; high school; Keble school for girls; and the Central, court of appeals, Y. M. C. A., co. orphan asylum, university, and school libraries. The city is the seat of a Protestant Episcopal and a Roman Catholic bishopric. There are Burnet and Genesee parks, the Onondaga Indian reservation, electric lights, electric street railroads, waterworks owned by the city and supplied from Skaneateles lake, about 130 churches, national, state, and savings banks, and numerous daily, weekly, and monthly periodicals. The U. S. census of 1890 reported for Syracuse, 1246 manufacturing establishments, employing \$22,853,424 capital and 17,518 persons, paying \$8,520,677 for wages and \$14,104,504 for materials, and having a combined output valued at \$29,297,241. The principal manufactures are soda ash, carbonate soda, salt, bicycles, clothing, plows, iron and steel, hardware, malt, beer, ale, chemicals, wax candles, typewriters, furniture, wheelbarrows, and castings. Pop. '90, 88,143.

SYRACUSE UNIVERSITY, at Syracuse, N. Y., comprises four colleges, liberal arts, fine arts, medicine, and law. There are a library of 50,000 volumes, an observatory with Alvan Clark telescope, museums with ample illustrative specimens and a gymnasium and athletic field. Courses with electives are offered in classics, philosophy, science, pedagogy, civil and electrical engineering, architecture, belles-lettres, music and painting. The faculty in 1897 numbered 110, and there were over 1100 students. Chancellor, James R. Day, S.T.D., LL.D.

SYRIA (Arab. *E'sham*, Turk. *Soristan*), a division of Asiatic Turkey bounded on the n. by portions of Asia Minor, on the w. by the Levant, and on the s. by Arabia Petræa; on the e. and s.e. its boundary is rendered indefinite, in great part, by the sands of the desert, but at length becomes fixed by the course of the Euphrates. It is divided into several governments, which frequently change their limits. They are usually named after the principal towns—Aleppo, Damascus, and Beyrout. The population in 1885 was 2,676,943, the area 115,144 sq. m. The whole region is traversed by a double mountain-chain—of which Lebanon (q.v.) forms the highest part—touching in its northern extremities the Alma Dagh (anc. *Mons Amanus*) and in its southern forming the Sinaitic range. The central part of this mountain system, which in many places exhibits the characteristics of a plateau, presents on the w. a steep front toward the Mediterranean, but on the e. rolls gradually away into the level uplands of the Syrian wilderness. The most noticeable features of the long furrow between the double ridge, beginning at its southern end, the gulf of Akaba, are the waterless wady of Arabah, the narrow, deep-sunken region known as *El Ghur*, through which the river Jordan flows, and which embraces the Dead sea and the sea of Galilee, and the vale of Cœle-Syria, and its great continuation northward, watered by the Nahr-el-Asy (anc. *Orontes*). The western ridge is broken through in three places: in the n. by the lower Orontes; in the middle near Tripolis,

where the chain of Lebanon properly terminates; and further s., near Tyre, by the Leontes. South of Tyre it recommences in the hill country of western Palestine (q. v.), which finally passes into the desert plateau of El Tyh, in the Sinaitic peninsula. The eastern ridge is less sharply defined, its most conspicuous elevations being Anti-Libanos, the mountains of Moab (east of the Dead Sea), and Mount Seir, overlooking the Wady Arabah. The principal rivers are the Orontes (q. v.), the Leontes, the Jordan (q. v.), the Barada or Abana, the river of Damascus. The only lakes worth mentioning are the Dead Sea (q. v.) and the Sea of Galilee.

Although Syria belongs to the countries comprised within the Asiatic rain-zone, yet in general the climate is excessively dry and hot, differing little from that of Arabia. Drought and scantiness of vegetation characterize almost equally the uplands and the valleys. Only where the mountains are lofty, the streams abundant, and the atmosphere somewhat maritime, as in the terraced slopes of Lebanon, do we find some approach to tropical luxuriance in flower, and fruit, and tree. Forests of evergreen, beautiful grassy pastures, and meadow-tracts are found there; and wheat, maize, rice, etc., are largely produced. The cultivation of the vine, the cotton tree, the mulberry, and also the finer sorts of fruits, as the olive and fig, is considerable, while indigo and sugarcane are raised in the valleys of the Jordan and the region round about the Dead sea. The fauna of Syria, like its climate and vegetation, is similar to that of Arabia. The camel is of almost as much importance as further s., and the Syrian deserts, particularly toward the n., are the home of gazelles, hyenas, jackals, bears, and buffaloes.

The greater part of the Syrian mountains is limestone; mountain limestone in Lebanon, chalk in Anti-Lebanon, and Jura limestone in Palestine. In the last of these volcanic formations occur, especially in the region of the Jordan and the Dead sea, where hot springs, beds of bitumen and sulphur, the shapes of the hills, and the frequent earthquakes afford unmistakable evidence of volcanic activity. Salt is the only mineral of much consequence, and is exported in considerable quantities; coal, however, is worked near Beyrout. Sheep, goats with hanging ears and silky hair, cattle, mules, and asses form, as in ancient times, a great part of the wealth of the inhabitants.

Silk is the chief article of manufacture—at Aleppo, Beyrout, Damascus, etc.—but cotton and woolen fabrics, gold and silver thread-stuffs, glass, earthenware, leather, soap, etc., are also manufactured in different parts of the country. The want of roads is a great hindrance to industrial activity. The first carriage-road was opened in 1863, between Beyrout and Damascus.

The religious sects of Syria are numerous. The Maronites (q. v.) number 482,000; Mutualis, 30,000; Yezidjis, 25,000; Nusairih (q. v.) or Ansyrieh, 80,000; Chaldeans or Nestorians (q. v.), 40,000; Syrians (q. v.) or Jacobites, 10,000; and Druses (q. v.), 90,000. The inhabitants are in some sense a mixed people, for the country has experienced many political vicissitudes, but by far the greatest number, whether Christians or Mohammedans, are of Shemitic origin, either Phenician, Aramaean, or Arabic. Their Turkish rulers, however, and such Turkomans and Kurds as we find settled in the n. of Syria, belong to the Turanian race. Arabic is everywhere spoken, and may be considered the national language, since the old Syriac or Aramaic tongue is wholly dead, except among the Nestorians of Kurdistan.

The history of Syria stretches far back into remote antiquity. In the time of Abraham (2,000 B.C.) Damascus was a city; in the oldest literature of Greece Sidon figures as the capital of a rich, populous, and civilized state; and in the Hebrew Scriptures, Canaan or Palestine is crowded with towns at the period of its conquest by Joshua; but, like most other so-called nations in early times, Syria did not form a single state; it was rather a congeries of independent states whose inhabitants belonged to the same race. Every important city had its king, whose normal occupation was fighting with his neighbors. Under David and Solomon something like political unity was achieved; yet it does not appear that these great rulers dispossessed of their territories the princes whom they subdued, but only made them tributary, and after their death things reverted to their previous condition. Rezin, a slave, then made himself master of Damascus, and extended the Damascene monarchy over all northern and central Syria; but the conquests of Tiglath-Pileser resulted in its becoming a province of the Assyrian empire. Subsequently the whole land, including Palestine, became part of the successive empires of Babylonia, Media, Persia, and Macedonia. Then followed the dynasty of the Seleucidæ (q. v.). After their fall Syria passed into the hands of the Romans, who retained it, though not continuously—for on several occasions the Persian Sassanidæ (q. v.) managed to wrest it from them—until the Arab conquest (7th c. A.D.). During the crusades (q. v.) of the middle ages several Christian principalities were established here, but endured only for a short period. Syria now became a possession of the sultans of Egypt, in whose time it was frightfully devastated by the Mongols. In the 16th c. it was conquered by the Turks, and has ever since formed part of the Turkish empire.

SYRIAC. I. The language is a dialect of the Aramean, anciently spoken through out Syria, the form preserved in literature being probably that of Edessa. After the Mohammedan conquest, 636 A.D., it was gradually displaced by the Arabic; and since the 13th c. it has been used only as an ecclesiastical language in the Syrian churches, and spoken corruptly in a few districts of mount Lebanon and on lake Oroomiah. This last has by the labors of the American missionaries been made a written language. The Syrian alphabet contains 22 letters, all consonants, read from right to left, and 5 vowels denoted by diacritical points. In grammar it shares the Aramaic peculiarities; its

vocabulary contains Persian, Greek, Latin, Arabic, Tartar, and even French and English words—traces of the nations that have ruled Syria. II. The literature corresponding to the condition of the country—which was continually subject to foreign dominion—has no freshness, is made up of translations, and largely on religious subjects. It may be divided into three periods: I. *Before the Mohammedan conquest*, 636. Syriac was then a spoken language, and the universities of Edessa and Nisibis were famous through the east. It produced the Peshito (i.e. the simple) version of the Bible, the oldest Syriac book extant, and accepted among all parties in the Syrian church. The Old Testament version was made by Christian translators directly from the Hebrew, and the New was made at Edessa in the 2d c., or the beginning of the 3d. II. 613–1318 was the period of decay; at the beginning Syriac and Arabic were both spoken, and at the end both were used in books. III. *From 1318 to the present time*. Arabic is the spoken language; and Syriac is cultivated only as an ecclesiastical language, and chiefly in the Maronite college at Rome. See **SHÉMITIC LANGUAGES**.

SYRIAC VERSIONS. Apart from the Peshito (q.v.), there were other Syriac versions of the Old Testament current among the Syrian Christians, although they did not acquire canonicity among them. These were chiefly translated from the LXX., and the best known among them is one drawn up from the text of the Hexapla (q.v.; compare also **ORIGENES**), which it follows most slavishly, without any regard for Syriac idiom or grammar. It contains the critical marks of Origen, and is moreover furnished with numerous variants, fragments from other Greek versions, and exegetical scholia. Bishop Paulus of Tela is supposed to have composed it at the instigation of bishop Athanasius, 617 A.D. There are now only a few (imperfect) MSS. extant of it—one in Paris, one in the Ambrosian library (a third, once in the possession of T. Masius, has disappeared), and further portions are found in the Nitrian collection in the British museum. The greater part of the Biblical books has been edited from it, but in separate publications. A complete edition is still a desideratum. An attempt is now being made toward a more complete edition of the Hexapla itself by a reconstruction of lost portions of the Greek, through the medium of the parallel Syriac passages preserved in this translation. Two other MSS. in the Paris library contain fragments of another Greco-Syriac version, by Jacob, bishop of Edessa, who, in 703 and 704 A.D., composed it from the Peshito and the above translation, which is probably to be understood in the sense of his having made a new recension of Paulus of Tela's work, corrected after the Peshito.

SYRIAN RITE, CHURCH OF, that portion of the oriental church which had its seat in Syria, and which was anciently comprehended in the patriarchate of Antioch, and (after that of Jerusalem obtained a distinct jurisdiction) in the patriarchate of Jerusalem. The Syrian church of the early centuries was exceedingly flourishing. Before the end of the 4th c., it numbered 119 distinct sees, with a Christian population of several millions. The first blow to the prosperity of the Syrian church was the fatal division which arose from the controversies on the incarnation. See **MONOPHYSITES, NESTORIANS, EUTYCHES, JACOBITES**. The Eutychnian heresy, in one or other of its forms, obtained wide extension in Syria; and the usual results of division ensued in the corruption and decay of true religion. The Moslem conquest accelerated the ruin thus begun; and from the 7th c. downward, this once flourishing church declined into a weak and spiritless community, whose chief seat was in the mountains, and whose best security from oppression lay in the belief on the part of the conquerors of their utterly fallen and contemptible condition. Under the head **MARONITES** has been detailed the most remarkable incident in the later history of the Syrian church. This branch of the eastern Christianity, although for the most part divided from the orthodox Greek church by the profession of Monophysitism, took part with the Greeks in their separation from the w., under Michael Cerularius; and the reunion of the Maronites to Rome had the remarkable result of establishing side by side, within the narrow limits occupied by the Christians under the Moslem rule in Syria, two distinct communities, speaking the same language, using the same liturgy, and following the same rites; and yet subject to two different patriarchs, and mutually regarding each other as heretics and apostates from the ancient creed of their country.

The chief peculiarity of the Syrian rite, as contradistinguished from the Greek, consists in its liturgy, and the language of that liturgy, which is Syriac, and with which the people, and in many cases the priests, are entirely unacquainted. The liturgy is known as the liturgy of St. James. The Syrians agree with the Greeks in the use of leavened bread, in administering communion under both heads, in permitting the marriage of priests (provided they marry before ordination), and in administering the unction of confirmation at the same time with baptism even to infants.

The Christian community of Syria may at present be divided into four classes: the Maronites, the Greeks (who are also called Melchites), the Monophysites, who are called Jacobites, and the primitive Syrian Christians (not Maronites), who are in communion with Rome. This last-named community forms the small remnant of the ancient Syrian church, which remained orthodox during the controversy on the incarnation, at the time of the general lapse into Monophysitism. To these are to be added the Christians of the Latin rite and a few Protestants. The Maronites number about 160,000; the Greeks are said to be about 180,000; the Jacobites of Syria and of Armenia proper are said to

reckon together about 40,000 families, of whom, however, probably scarcely 10,000 can be set down to the account of the Syrian church. The non-Maronite Syrians who follow their national rite, but are in communion with Rome, are supposed to amount to about 5,000. The resident Latins are chiefly members of the religious orders who from immemorial time possess convents in the Holy Land, and European Catholics, who have settled permanently, or for a time, at Jerusalem, Beyrout, and Damascus. None of these can in any way be regarded as belonging to the Syrian church. It may be well to add, that the belief, and in most particulars the disciplinary practice of these several classes coincide substantially with those respectively of the same communities in the other churches of the east. All (with the exception of the Maronites and the few united Syrians of the Greek communion reject the supremacy of the Roman see. The Syrians of the Greek communion reject the double procession of the Holy Ghost; and the Jacobites firmly maintain their old tenet of Eutychianism. Among them all are to be found monks and religious females. All enforced celibacy on their bishops, and refuse to priests the privilege of contracting a second marriage, or of marrying after ordination. The practice of fasting prevails among all alike. They receive and practice the invocation of saints and prayers for the dead, and the use of painted, although not of graven images. Many particulars regarding them are to be gleaned from the memoirs of recent missionaries of the several denominations, among which the letters published from time to time by the French society for the propagation of the faith, are particularly full. For the modern Nestorians, and the Syrian Christians of Travancore, see NESTORIANS.

SYRINGA, a genus of plants of the olive family (order *oleaceæ*). The English name of the genus is lilac (q.v.), and is derived from *ylag*, the Persian for flower. *Syringa vulgaris*, the common lilac, is a native of Persia, Hungary, and the borders of the Danube. Dr. Sibthorp found it wild on mount Hæmus, but not in Greece. It has been long cultivated by the Turks. It is one of the few shrubs that are not injured by the smoke of cities, and it flourishes in perfection in most of the squares of London. It grows very fast, from 20 to 36 in. every year. The Persian lilac, *S. Persica*, is a small shrub from 4 to 6 ft. high, and is one of the most ornamental of low deciduous shrubs. When planted in pots and forced, it may be made to flower at Christmas; but under the circumstances the flowers will lose their ordinary fragrance. There are three varieties of this species in the English nurseries. *S. Chinensis* is a native of China. It is intermediate between *S. vulgaris* and *S. Persica*. It grows vigorously to a height of from 10 to 12 ft. The *lilas de Marty* and *lilas Sangé* are varieties. *Syringa* is also a name improperly applied to the mock-orange or Philadelphus (q.v.).

SYRINGE (Gr. *syrix*, a pipe), a hydraulic instrument, consisting of a cylinder of metal or glass, having a conical nozzle at one end, and the other fitted with an air-tight piston. The nozzle being inserted in a liquid, the retraction of the piston draws the liquid into the cylinder, on the principle of the pump (q.v.), and by its forward pressure the liquid is expelled from the nozzle in the form of a jet.

SYRINX (Pans-Pipes), a simple instrument of reeds, probably the most ancient of all musical instruments. It is thought to be identical with the Hebrew Ugab, mentioned in the Bible. It is known in China with twelve tubes of bamboo, and in Peru it is made of cane, or soapstone. It is seen in ancient MSS. and on bas-reliefs. The Greeks supposed it to have been made by the god Pan out of reeds. It was formed of seven, eight, or nine short hollow reeds cut in graduated lengths, so as to produce a musical scale, and then fixed together by wax. The lower ends of the reeds were closed and the upper ones open and on a level, so that the lips could easily pass from one pipe to another.

SYRRHAPTÉS, a genus of birds of the grouse family (*tetraonidæ*), of which only one species is known (*S. Pallasii*), a native of the deserts of Tartary, abundant in the neighborhood of lake Baikal. From its peculiar characters, which led Pallas to call it *tetrao paradoxus*, it has received the somewhat pedantic name of *heteroclitæ grouse*. (A word is called *heteroclitæ* by grammarians which departs from the ordinary forms of declension.) The legs and toes are short, and densely feathered; and the toes are joined together for the greater part of their length. The bird walks with difficulty, but flies very well, although in general only for short distances. The wings and tail are very long, terminating in remarkably long, slender, pointed plumes.

SYRTIS MAJOR and **SYRTIS MINOR**, the ancient name of two gulfs of the Mediterranean sea, on the n. coast of Africa. The former (now called the *gulf of Sidra*) lies between cape Mesurata, in Tripoli, and the table-lands of Barca, and forms the most southern part of the Mediterranean. The latter (now called the *gulf of Cabes*) lies to the n.w., between Tunis and Tripoli. The shores of both are inhospitable, and abound in quicksands, which, carried by the wind, are said by the ancients to have frequently overwhelmed ships, and the reports of modern travelers to some extent confirm these old traditions. Their waters are (or were) dangerous to sailors, on account of the shallows, sand-banks, and sunken rocks that abound in them. The name Syrtis is derived from an Arabic word *sert*, meaning a desert.

SYRUP, *sirup*, *sherbet*, and *shrub* are all derived from the Arabic *srb*; the first through the Latin, the second through the Persian, and the third through the Hindu.

Syrup, in its simplest meaning, is a saturated solution of sugar boiled to prevent fermentation; but it also means the juice of fruits saturated with sugar, and many flavored liquids treated in the same way. Generally speaking, the finest refined sugar is used; and every effort is made to get the syrup very clear and free from all feculent matter. Syrups of fruits are much used on the continent to mingle with water for drink, and are very wholesome. They are also used in America, especially as flavorings for soda water, there being many varieties of syrup.

SYSTYLE, an arrangement of classic columns in which the intercolumniation is equal to twice the diameter of the column.

SYZРАН', a t. of central Russia, in the gov. of Simbirsk, on the right bank of the Volga, 80 m. s. of Simbirsk. It owes its foundation to its advantageous commercial position on the Volga, and in the middle of a district teeming with agricultural produce. Large quantities of corn are exported. Pop. '94, 30,229.

SZABADKA. See THERESIOPEL.

SZARVAS, a t. of Hungary, in the co. of Bekes, on the Körös, 80 m. s. e. of Budapest. It has a considerable trade in corn and cattle. Pop. '90, 24,393.

SZATMAR-NEMET, a t. of Hungary, on the Szamos, 68 m. n. e. of Debreczin; pop. '90, 20,736.

SZECHENYI, ISTVÁN, Count, 1792-1860; b. Vienna, of a noble and wealthy Hungarian family. He served in the Austrian army in the wars with Napoleon, and afterward traveled through Europe. Clearly seeing the great need for reform and advance in the material and social status of the Hungarian people, he gave liberally of both time and money in bringing this about. Among his acts were the endowment of the Hungarian academy; the founding of a society for improvement in horse-breeding, a most important occupation in Hungary; and the establishment of schools of acting and music. To his exertions were due the erection of the great suspension bridge between Pesth and Ofen, the removal of obstacles to navigation at the "Iron Gates," and the introduction of steamboats on the Danube. He became minister of public works. He opposed the revolutionary measures of Kossuth, and when the revolution of 1848 broke out, became insane, and though he recovered, continued to reside at the Döbling asylum, where he committed suicide after a domiciliary visit by the Austrian police.

SZE-CHUEN (Four streams), a vast province of western China, and the largest of the 18. It has an area three times greater than that of England, but the population is scanty. The Kincha-Kiang, or "Golden sanded river," which rises in the southern slopes of the great Thibetan range, flows through Sze-chuen, and after receiving several tributaries, it becomes, before leaving the province, the famous Yang-tse-Kiang. In its course it passes, at right angles and by narrow gorges, through a succession of ranges of hills, which have a direction from n. to south. The people of Sze-chuen cannot always force a subsistence from their stubborn soil. Famines are not uncommon, when whole families are starved to death, and thousands subsist on a mixture of rice, roots, and common earth. Coal is abundant, but of inferior quality. Salt is evaporated from brine. There is some petroleum; and opium, tea, silk, and tobacco are among the products. Area, 166,800 sq. m.; pop. '82, 67,712,897.

SZEGEDIN, is the second largest town in Hungary, but it was almost completely destroyed by a terrible flood in Mar., 1879. In this hardly paralleled catastrophe, of the 7000 houses of the city, only 350 were left standing. The ruin to property was immense; the loss of life was given at 2000. Szegedin is situated upon the low ground where the Theiss is joined by the Maros, 118 m. s.e. of Budapest. It manufactures great quantities of soda, soap, coarse cloth, etc., has the largest wharves on the Theiss, and carries on an extensive trade in wood, corn, wine, tobacco, and salt. Its markets rank next to those of Pesth and Debreczin. Pop. '90, 87,210.

SZEGSZARD, a t. of Hungary, capital of the county of Tolna, near the right bank of the Danube, 80 m. s.s.w. of Pesth. Here excellent red wine is made. Pop. '90, 14,325.

SZENTA. See ZENTA.

SZENTES', a market t. of Hungary, 28 m. n.e. of Szegedin, near the left bank of the Theiss. The commune contained (1890) 30,758 inhabitants, who are chiefly engaged in the wine culture.

SZOLNOK', a t. of Hungary, on the Theiss, 66 m. e.s.e. of Pesth. It contains important salt magazines, and is the center of the traffic by steamers on the Theiss, and an important railway station. Pop. '90, 20,748.

SZOLNOK DOBOKA, a co. in Hungary, bounded on the s.e. by Transylvania, within which it was formerly included, drained by the affluents of the Szamos river; 1985 sq. m.; pop. '90, 217,550. The surface is mountainous and well wooded. The soil in the valleys is fertile. The principal productions are corn, rye, oats, tobacco, and wines. Capital, Des.

T

T, THE twentieth letter of the English alphabet, is the sharp or mute of the lingual series, *t*, *d*, *th* (*dh*). It is produced by pressing the fore-part of the tongue against the front of the palate. The name in Shemitic (*Tau*) signifies a mark (in the form of a cross.) The Shemitic tongues had another *t*-sound, which became the Greek *θ* (*th*). This aspirated *t* is wanting in Latin and its derivatives; it is also foreign to high-German, although the Gothic and other low-German tongues (English) possess it. The Gothic *th* has become in high-German *d*. In the *spelling* of high-German, *th* occurs not unfrequently; but it is never pronounced, and the introduction of it being considered by students of the language an aberration, there is a tendency to drop the *h*. There is evidence that in Latin, at an early period, *t* before *i* was sibilated so as to sound like *ts* or *z*. See letter C. Before *s*, *t* was frequently dropped; as *fons* for *fontes*, *sors* for *sortes*. Final *t* was in Latin pronounced but faintly, and inscriptions show that in popular speech it was often dropped; e.g., *fecce* for *fecit*, *vixse* for *vixit*. Thus the modern Romanic languages have inherited the loss of the pronominal ending *t* from their common mother. In French, *t* between two vowels has been elided; as *père mère*, from *pater, mater*. In the corresponding words of the allied languages, *t* is often interchanged with other letters. T in Sanskrit, Greek, and Latin becomes *th* in Gothic and English, and *d* in high-German; thus Lat. *tres* (Sans. *trayas*), Goth. *thraiss*, Eng. *three*, Ger. *drei*; Lat. *tectum* (Gr. *tegos*), Goth. *thak*, Eng. *thatch* or *thack*, Ger. *dach*; Lat. *frater*, Goth. *brothar*, Eng. *brother*, Ger. *bruder*. In German, the *t* of the English is often represented by *z*, as Eng. *two* = Ger. *zwei*; Eng. *toll* = Ger. *zoll*; while German *t* or *th* becomes Eng. *d*, as Ger. *tag*, *thau* = Eng. *day*, *dew*. A more remarkable interchange is seen in Lat. *lacrima* = Eng. *tear*. See PHILOLOGY.

TAAFE, COUNT EDWARD FRANCIS JOSEPH, in the Austrian peerage, and Viscount Taafe of Corren, and Baron of Ballymote, Sligo, in the Irish peerage, was b. at Prague, Feb. 24th, 1833. He was brought up in companionship with the present Emperor Francis Joseph. The Count is a descendant of that powerful nobleman of the name who proceeded from Ireland and made a great name in the Germanic Empire. He was appointed Governor of Salzburg in 1863. In 1867 he became Austrian Minister of the Interior and Vice-President of the Cisleithan ministry. In 1869-70 he served as Minister President. In 1871 he accepted the office of Governor of the Tyrol and Vorarlberg. In 1880 he was summoned to form a new cabinet, over which he presided until 1893. The distinguishing feature of Count Taafe's Clerical and Federalistic administration has been to give greater weight to the Slav nationalities, especially the Czechs and the Poles, as well as to the Clericals, in the public affairs of the Empire; and to conciliate the divergent nationalities comprising the kingdom. He d. Nov. 29, 1895.

TABANIDÆ, a numerous family of dipterous insects, of the section *proboscidea*, which live by sucking the blood of horses, oxen, and other animals, and are popularly known by the name of GAD-FLY, which, however, is often given also to some of the *æstridæ* (see BOT). The insects called cleg (q.v.) are of this family. The proboscis is exerted, and is generally terminated by two lips; the palpi are also exerted; the antennæ are three-jointed, the third joint consisting of a number of rings. The tabanidæ fly with a buzzing noise. They are very annoying to cattle in the end of spring and early part of summer; and where they abound, the skins of cattle are often streaked with blood from their bites. The LARGE GAD-FLY (*T. bovinus*) is more common in some parts of the continent of Europe than anywhere in Britain, and is rarer in Scotland than in England. Some of them inhabit the deserts of Arabia and Africa, and attack camels in prodigious numbers.

TABARD (Fr. *tabarre* from *tabardum*, low Lat.), a military garment in general use in the latter half of the 15th and beginning of the 16th c., which succeeded the *Jupon* and *Cyclas*. It fitted closely to the body, was open at the sides, had wide sleeves or flaps reaching to the elbow, and displayed the armorial ensigns of the wearer on the back and front, as well as on the sleeves. About the middle of the 16th c., the tabard ceased to be used except by the officers at arms, who have down to the present time continued to wear tabards embroidered with the arms of the sovereign.

TABASCO, a state in s.e. Mexico; bounded on the n. by the gulf of Mexico, on the e. by Campeachy, on the s. by Chiapas and Guatemala, and on the w. by Vera Cruz; drained by the Tabasco, the Usumasinta, and other streams; 10,072 sq. m.; pop. '95, 134,794. The surface is mostly low and level, with a large area of marsh. The climate is very hot and unhealthy. Mahogany and other valuable woods abound. The principal productions are rice, tobacco, coffee, sugar-cane, pepper, indigo, and honey. Capital, San Juan Battista.

TABASHEER, a substance sometimes found in the cavities or tubular parts of the stems of bamboos and other large grasses. It consists chiefly of silica, with a little lime and vegetable matter, or sometimes of silica and potash, in the proportions of about 70 parts of silica and 30 of potash. It appears to be formed by extravasation of the juices of the plant, in consequence of some diseased condition of the nodes or joints. It is in

high repute among the Hindus as a tonic, and is prepared by imperfect calcination and trituration.

TABBY, or **TABBYING**, another name for watering fabrics. See **MOIRE**. It is usually applied to stuffs or worsted cloths instead of silks.

TABERNACLE (Heb. *Ohel Moed* = tent of meeting, *scil.*, between God and man; **LXX.** *Skene*, Vulg. *Tabernaculum Fœderis*), or, more fully, "tabernacle of the congregation," was the tent first erected by Moses in the desert as a visible symbol of the divine Presence in the midst of the people. It was the place where he went to receive his inspirations as their representative when they "came to seek Jehovah." A cloudy pillar descended and stood at the door of the tabernacle while "the Lord spake to Moses." The detailed description of the tabernacle contained in **Ex. xxv. seqq., xxxvi. seqq.**, renders more than a brief outline superfluous in this place. Suffice it to mention that it was divided into the "sanctuary" proper—which formed the front part, and the dimensions of which were 20 cubits in length, 10 in width, and 10 in height—and the "holy of holies," which was 10 cubits square and 10 high. A kind of court-yard, formed by curtains suspended between columns, ran round the tabernacle, 100 cubits long and 50 wide. The entrance was toward the east—the rising of the sun—and closed by another costly curtain, into which, like unto the first covering, figures of "cherubim" were woven. The surrounding court was much larger on this eastern than on the western side, for here it was that the people assembled for the purpose of worship. Here also stood the altar, made of acacia-wood, upon which a perpetual fire was kept burning, and the brazen laver. The *sanctuary* contained the gilded table with the showbread to the right, the golden candlestick with the seven branches to the left, and between both the "golden altar," or the "altar of incense," upon which the high-priest burned incense in the morning and evening. In the holy of holies, the holy ark, or ark of the covenant, alone was kept; a box of acacia-wood, plated with pure gold both in and outside, containing the two tables of the Ten Commandments. On the top of it were the two cherubim, their faces turned toward each other; and between them there was the symbolical presence of Jehovah (the Shechinah), to which Moses appealed for guidance.

Only once a year, on the Day of Atonement, the high-priest was allowed to enter the holy of holies, while the sanctuary was the ordinary place of the priests, and the court that of the Levites. The tribe of Levi was also that to which the place nearest to the tabernacle, around which the 12 tribes were grouped, was assigned, as it also was the duty of its members to convey the building from place to place during the migrations.

The tabernacle, after the people had settled in Canaan, was erected at Shiloh, where it was still found at the time of Saul, although the ark of the covenant itself had been carried away by the Philistines, in the time of Eli, and when restored, placed at Kirjath-jearim. Nor was the tabernacle of Shiloh the only sanctuary, as it was intended to be. We find other local sanctuaries with priests—at Bethel, Nob, Sichem, Mizpah, etc.—at which even Samuel worshiped, as in legally instituted places. When David is reported to have removed the ark from Kirjath-jearim to Jerusalem, nothing is said about the tabernacle of Shiloh; on the contrary, David erected a new one on purpose for the ark. It seems probable that it was removed at some time or other from Shiloh to Nob, and thence to Gibeon, from whence Solomon seems to have fetched it away, with all its vessels, thus putting an end to the double worship that under David had divided the faithful between Gibeon, where Zadok officiated, and Jerusalem with Asaph's worship. Nothing is further known of the tabernacle, which, besides being a symbol of God's presence, had also served the purpose of a visible political and religious link between the tribes. As a safeguard against idolatry and unlimited sacrificial worship, however, it did not prove effective enough.

TABERNACLE, (Lat. *tabernaculum, armarium*), in the Roman Catholic church, is the name given to the receptacle in which the consecrated elements of the Eucharist are retained. The name is derived by analogy from the tabernacle of the old law, and in form the Roman Catholic tabernacle bears a general resemblance to the Jewish original. By the present discipline, the tabernacle is commonly a small structure of marble, metal, or wood, placed at the posterior part of the altar, and of costly material and workmanship. Even when the exterior structure is of marble or metal, there is commonly an inner receptacle of wood (properly cedar), lined with silk. The tabernacle is appropriated exclusively to the reservation of the Eucharist, and it is prohibited to keep within it any other object, however sacred, as the chrism, relics of saints, the altar vessels, etc. A lamp is constantly kept burning before the tabernacle, which is ordered to be kept at all times carefully locked, the key being retained by the clergy, to whom it is forbidden to intrust it to any lay person, even the sacristan or other official of the church.

TABERNACLES, FEAST OF (Heb. *Succoth*, **LXX.** *Heorte skenon*, Vulg. *Feria tabernaculorum*), a Hebrew feast of seven days' duration, beginning on the fifteenth day of the seventh month (Tishri), and instituted principally in memory of the nomad life of the people in the desert, and the booths or tents used on their march. Besides this signification, it also had an agricultural one, like the other two pilgrimage festivals, the passah and the feast of weeks. It was emphatically the feast of "ingathering"—i.e., the close of the labors of the field—the harvest of all the fruits, of the corn, the wine, and

the oil. During this feast, the great bulk of the people were enjoined to dwell in booths, which we learn from Nehemiah viii. 15, were made of olive, pine, myrtle, palm, and other branches, and were erected on the roofs of houses, and in the courts and streets. The scriptural injunction, to take trees and "boughs of goodly branches of palm trees," etc., was by tradition explained to mean a bunch made of palm, myrtle, and willow branches, and the esog-fruit, a species of citron which the faithful carried in procession during these seven days in the temple; while those who did not visit the temple only said a benediction over it on the first day. The Sadducees and Karaites, however, demurred to this explanation, taking the passage merely to refer to the construction of the booths. Special sacrifices, and a greater number of burnt-offerings than on any other festival, were offered up on this; and on it also the law was to be read to the people every seventh year. It was emphatically called *the* festival, and was the most joyous of them all. There was especially, during the time of the temple, the "joy of the libation," consisting of the priest's fetching, during the morning sacrifice of each day, water from the well of Siloah, and pouring it out, with the accompaniment of music and hymns. There was further a grand illumination in the evening in the court of women, which is said to have lighted up the whole city of Jerusalem; and during and after which, dancing and singing took place. On each day the trumpets were sounded 21 times. At the end of the seven days' joy, an eighth day of solemn rest was celebrated, which was perfectly distinct from the other days both in its sacrifices and in its general service. The bunch was laid aside, the booths were relinquished, and a sin offering—in expiation of transgressions that might have taken place during the hilarity of the previous feast-days—was slaughtered.

Three distinct times we find the inauguration of the temple celebrated on this important festival, by Solomon, Ezra, and Judas Maccabæus, although with regard to the festival itself it would seem from Nehemiah viii. 17, that it never had been properly celebrated before the exile. The observances of the booths and the harvest-bunches are still in force with the strict adherents of traditional Judaism, although the agricultural signification of the festival to them can only be a historical or poetical reminiscence. It has been well observed of old, that no festival could have been more apt to inculcate the fundamental principle of Judaism—viz., the equality of all men, than this, which enjoined that every one should live for a time in primitive dwellings, without distinction of rank, or station, or fortune, and should rejoice in the fruits of the last harvest on the hallowed spot, together with the whole people of the land, "before the Lord."

TABERNÆMONTANA. See COW-TREE and FORBIDDEN FRUIT.

TABES DORSALIS, an affection of the nervous system, now known in medicine as *locomotor ataxy*. *Tabes dorsalis* was so named by Romberg of Berlin; but Dr. Todd of London in 1847 first recognized its true nature, and specially insisted on the distinctions to be drawn between *tabes dorsalis* and *paraplegia* (see PARALYSIS). The name of *locomotor ataxy* was first applied to the affection by Dr. Duchenne of Paris. It is characterized by a want of power in harmonizing the action of certain muscles, the absence of such co-ordinating power being first apparent in the lower extremities, and the gait in consequence being straggling and unsteady. True paralysis is absent, but sensitiveness is diminished, and neuralgic pains are present in the legs and feet. The loss of power progresses, and the later stages of the malady are marked by such symptoms as disordered vision, incontinence of urine, and exhaustion. The duration of this disease varies. It may run its course in a few months, or be prolonged over years. The *etiology* or *causes* of *tabes dorsalis* are still obscure. Mr. Lockhart Clarke has shown that a peculiar change in the posterior columns of the spinal cord, and in the posterior or sensory roots of the spinal nerves, accompanies this disease. Prolonged exposure to cold and damp, drunkenness, sexual excesses, masturbation, and like causes have been credited with inducing the disease. It is alleged to be more common in males than in females, and subjects between the ages of 30 and 50 are said to suffer most frequently from its attack. The characteristic movements in *tabes dorsalis* are worthy of note. The patient has an unsteady gait, and walks like a drunken person, but soon recovers his bearing in some degree. A difficulty in carrying out the intents of the will is experienced, and in picking up an object one hand is employed to steady the other. When the eyes are shut, the patient walks with extreme difficulty. *Tabes dorsalis* may be distinguished from disease of the cerebellum by the absence of the characteristic pain at the back of the head, and vomiting. The *prognosis* of *tabes dorsalis* is very unfavorable. Its progress may be retarded, but the prospect of ultimate cure is well nigh hopeless. The *treatment*, as may readily be understood, is limited to the improvement of the general health, rather than to any specific remedies. Warm clothing, nutritious food, and rest are the chief items in the course of treatment prescribed for this disease; while opiates are indicated for the relief of the neuralgic pains. Sulphur baths have been prescribed in the earlier stages to relieve the numbness, and attention requires to be paid to the bowels with a view of alleviating constipation.

TABINET, a rich kind of cloth, chiefly used for window-curtains. It consists of a warp of silk and a weft of wool-yarn, of the same kind as that used in making poplin. It has the appearance of a fine damask, and is usually enriched with diaper patterns.

TABLETURE, a method of notation used in the 15th and 16th centuries. Its name is derived from the Latin, a table, or flat surface. At first it was chiefly employed for the lutes and viols. Various systems of writing in Tablature were in use at an early date, traceable directly from the gamut of Guido d'Arezzo, but without the stave. The more modern Tablature was arranged in the 16th century. Its general character was the same in Germany, England, France, Spain, and Italy, though each nation had variations which subsequently resulted in a diversity of notation. The methods became so complicated that treatises were written upon the subject. Among these were *Brieve et facile Instruction pour apprendre la Tablature* (Paris, 1551); *Musica Instrumentalis*, by Agricola (Wittenberg, 1529); and *Musick's Monument*, by Thomas Mace (London, 1676). See Mendel's Lexicon, Grove's *Dictionary of Music and Musicians*, and Stainer and Barrett's *Dictionary of Musical Terms*.

TABLEAUX VIVANTS (i.e., living pictures), representations of works of painting and sculpture, or of scenes from history or fiction, by living persons. They are said to have been invented by Mme. de Genlis, when she had charge of the education of the children of the duke of Orleans. They have long been common in theatres, and have more recently become an amusement of private circles. In an æsthetic point of view they are highly commendable.

TABLE D'HÔTE (Fr., "landlord's table") was a name originally used in France to denote a dinner at which the landlord of the inn was accustomed to preside. At the present day it is applied to a full dinner served in courses; used especially with reference to such a dinner served in a hotel or public dining-room.

TABLE-LANDS, or **PLATEAUS**, are extensive plains at a considerable elevation above the sea, whose boundaries are either ranges of mountains much higher on the side away from than on the side next to the table-lands; or steep acclivities, sloping from the level of the plateaus to the surrounding country. They are often traversed by mountain chains, and occasionally even lose the character of plains altogether, being mere conglomerations of hills. The chief table-lands are in Europe, central Spain; in America, the Oregon territory, the great salt plain of Utah, the north and center of Brazil; in Africa, the interior of Barbary; while in Asia, almost the whole of the south and center of the continent consists of plateaus, which rise terrace above terrace till they culminate in that of Thibet. Of the Asiatic plateaus, the principal are: that of Asia Minor (3,280 ft. above sea-level), Armenia (7,000 ft.), Persia or Iran (3,000 ft.), Mysore (4,000-5,000 ft.), Deccan (1500-2,000 ft.), Thibet (12,000-17,000 ft.), and Chinese Tartary (3,000-4,300 ft.). These table-lands are generally accounted for by the supposition of a more extensive and uniform action of the upheaving force than that which produced mountains; and satisfactory indications of the former action being quite recent, and long subsequent to the latter, are occasionally discovered.

TABLE MOUNT. See CAPE TOWN.

TABLES, LUNAR, are tabular lists of the values of the elements of the moon's orbit, as planetary tables are those of the elements of the planets' paths; but the term is also occasionally employed to denote the tabulated angular distances of the moon from certain stars at fixed epochs, as given in the *Nautical Almanac* (q.v.). See LATITUDE.

TABLE-TURNING. See ANIMAL MAGNETISM; SPIRITUALISM.

TABOO. See TABU.

TABOR, a celebrated mountain of northern Palestine, rising solitarily in the north-eastern part of the plain of Esdraelon, to about the height of 1800 ft. and commanding the most extensive and probably the most magnificent prospect in the Holy Land. Eastward, the eye catches a gleam of the waters of the Galilean sea, 15 m. distant; while the whole picturesque outline of its deep-sunken basin, of the rolling trans-Jordanic plateau, and the course of the sacred river itself, is clearly traceable; westward, stretch away into the dim horizon the rich plains of Galilee, rising up into the dark-green ridges of Carmel, overhanging the Levant; on the north and north-east, the snow covered heights of Hermon (see LEBANON) glitter pale over the intervening hills; while to the south, the view embraces the fatal heights of Gilboa and the confused landscapes of Samaria. Tabor itself is at present thickly clad with forests of oak, pistacias, etc., the haunt of wolves, wild-boars, lynxes, and various kinds of reptiles. Its beauty alone would be sufficient to insure it distinguished mention among the mountains of Palestine, but it owes its celebrity even more to its having been regarded from an early period as the mount of Transfiguration. This opinion, however, is now all but universally abandoned, as there is strong evidence of its summit having been then occupied by a city; and travelers are disposed to look for the scene of this supernatural incident further north, in the neighborhood of Hermon. In the times of the crusaders, Tabor was studded with churches and monasteries, relics of which, as well as of Roman and Saracenic structures, still remain.

TABOR, a small drum, played with one stick, in combination with a fife. It was formerly used in war, but has now given place to the kettle-drum.

TABORITES (a sect of the Hussites in Bohemia) derived their name from their fortress of Tabor, near the river Luschnitz, an affluent of the Moldau, 49 m. s.s.e. of Prague. There is now a small town at the place, which had a population (1890) of 8440, and carries on

some woollen manufactures, etc.—The first leader of the Taborites was John Ziska (q.v.) of Trocynow. Under him was Nicolas von Hussinecz, who repelled the imperial army from Tabor in 1420. The Calixtines, desirous of the peace of the country, offered the throne of Bohemia first to king Ladislas of Poland, then to the grand duke Witold of Lithuania, and afterward to his brother Coribut. Ziska refused his consent, and thus these parties became completely separated. In the years 1420 and 1421 both of them set forth their creed in a number of articles. The Taborites absolutely rejected all ordinances of the church not expressly appointed in the holy Scriptures. Both parties were united by common danger in opposition to a common enemy. In 1422 Ziska defeated the imperialists at Deutschbrot, and thereafter met with uninterrupted success in a number of minor conflicts; and in 1424 Prague was saved from destruction only by submitting to hard terms of peace. After Ziska's death, Procop (q.v.) the Greater, or Procop Rasa (the Shaver), and Procop the Less were the leaders. In 1427 and in 1431 they gained great victories at Miess and Tachau over the mercenary crusaders of the German empire, and till 1432 their incursions were the dread of the neighboring countries. The council of Basel, finding them still unconquered in 1433, proceeded to treat with them; and the Calixtines entered into an arrangement, known as the *Prague compact*, which, however, was despised by the Taborites and the Orphans, as that section of the Taborites who considered Ziska as irreplaceable, had come to be termed. The Taborites and Orphans were completely defeated at Böhmisschbrot on May 30, 1434, by the now united forces of the Roman Catholics and the Calixtines. In the treaty of Iglau in 1436, the emperor Sigismund confirmed the compact, and promised religious and political liberty. The civil war, however, continued till king Ladislas in the diet at Kuttenberg, in 1485, established a religious peace, securing both Roman Catholics and Calixtines in their possessions. The Taborites were eventually lost in the sect of Bohemian Brethren (q.v.), which arose from among them.

TABRIZ (pronounced and frequently written *Tabreez*), a great and ancient city of Persia, capital of the province of Azerbaijan, 40 m. e. of lake Urumiah, and on the Aji, which flows s.w. into that lake. The town is surrounded by a ditch and a brick wall, pierced by 7 gates. It forms an oblong of gardens and houses, 2½ m. long; stands 4,000 ft. above sea-level, but nevertheless has the appearance of being shut in by mountains. The streets are broader and cleaner than in most eastern cities, but they are flanked as usual by the pits from which the earth required for their houses was taken; the houses are infested with noxious insects; and the bazaars are roofed with sticks, and are dark and dirty. Water, however, is comparatively plentiful. The chief buildings of Tabriz are not specially striking. Perhaps the principal architectural feature of the town is the fine ruin, Kabūd Masjid, or "blue mosque," about 300 years old, and in part covered with blue tiles beautifully arabesqued. The citadel is a spacious edifice of burned brick, the walls of which, however, have been cracked in many places by earthquakes. Tabriz is the seat of a varied industry, in which leather, arms, shawls, tobacco, and silk manufactures, and gold and silver smiths' work alone are of importance; recently it has also become the emporium of an extensive trade, the exact value of which, however, is not known, owing to the careless manner in which the custom-house officials transact their business, and to the prevalence of smuggling.

Tabriz, the ancient *Tauris*, became the capital of Tiridates III., king of Armenia, in 297 A.D., and was probably at that time an old city. In 791 A.D. it was enlarged and greatly embellished by Zobaidah, the wife of Harūn-er-Rashid. In 858, and again in 1041, the city was devastated by an earthquake. It was taken and sacked by Timur in 1392, and was soon after seized by the Turkomans, from whom it was taken by the Persians in 1500. In 1721 it was again visited by a dreadful earthquake, and on this occasion 80,000 persons are said to have perished. It has been several times in the hands of the Turks, but was finally taken from them by Nadir shah in 1730. Tabriz is a city of Turks, and Turkish is the language spoken. Pop. estimated at 180,000.

TABU, **TAPU**, or **TAMBU**, a Polynesian term, denoting an institution found everywhere, and always essentially the same, in the Polynesian islands and in New Zealand. Its primary meanings seem to be exactly the same as those of the Hebrew *to'ebah*. This word, like the Greek *anathema*, the Latin *sacer*, and the French *sacre* (and the corresponding and similar terms in most languages), has a double meaning—a good sense and a bad; it signifies on the one hand, sacred, consecrated; on the other hand, accursed, abominable, unholy. It results from a thing being held sacred, that certain acts are forbidden with reference to it, and from any act being deemed abominable, that it is forbidden; a notion of prohibition thus attaches to the word tabu, and this is in many cases, the most prominent notion connected with it. The term is often used substantively in the sense of a prohibition, a prohibitory commandment. If a burial ground has been consecrated, it is tabu; to fight in it is then an act sacrilegious and prohibited, and this also is tabu; moreover, those persons are tabu who have violated its sanctity by fighting in it, and they are, loosely and popularly, said to have broken the tabu. This example illustrates all the uses of the word. It has furnished to the English language the now familiar phrase of being "tabooed"= forbidden.

The extent to which, among the Polynesians and New Zealanders, things and acts are tabu, must appear almost incredible to Europeans unaware of the facts of savage life

Without much detail, it is impossible to convey any idea of it. The prohibitions, however, divide into two classes: one consisting of traditional rules, binding upon all, acting through religious terror equally upon chiefs and people; the other, of prohibitions imposed from time to time, obviously with the view of maintaining or extending the authority of the chiefs. Those of the first class are by far the most remarkable. Of the most important of them—those bearing upon what are called sacred things, those relating to the person of the chief, and those relating to intercourse between relatives—a few examples may be given.

Any house or piece of ground consecrated to a god is tabu, and thus affords an inviolable shelter to men fleeing from an enemy. *A fortiori*, all temples are tabu. To sit upon or to touch the threshold of a temple is tabu to all except chiefs of the first order, the lesser chiefs may stride over the threshold, but common persons pass over it on their hands and knees. It is tabu to eat the plant or animal believed to be the shrine of one's tutelary god. To come in the way of a funeral procession is severely tabu, for it is believed that the gods accompany the procession; if any person were to disregard the warning chant of the mourners, they would rush at him and put him to death. Again, to touch the person of a chief is tabu to his inferiors; also, to touch anything belonging to him, to eat in his presence, to eat anything he has touched, or to mention his name. And a chief's threshold is as sacred as that of a temple, and must be passed over in the same manner. It is strictly tabu to touch a dead chief or anything which belonged to him, or any of the clothes or utensils employed in his interment; even those employed in laying out the body pay the penalty of infringing this prohibition. The interdict upon family intercourse varies in extent in different places. In the Tonga islands it was tabu to mention the name of father, mother, father-in-law, mother-in-law; also to touch these relatives, to eat in their presence (unless with the back turned, when constructively the person was not in their presence), or to eat anything which they had touched. In the Fiji islands, generally, it is tabu for brother and sister, first cousins, father-in-law and son-in-law, mother-in-law and daughter-in-law, brother-in-law and sister-in-law, to speak together, or to eat from the same dish. Husband and wife, too, are forbidden to eat from the same dish. In some places a father may not speak to his son after he has passed his 15th year. In an immense number of cases, equally extraordinary, the tabu is used to enforce the prevailing ideas of social propriety. It interferes with cooking, eating, dressing, speaking; scarcely anything is too minute to be regulated by it.

The traditional tabu also supplies to some extent the place of laws and a police. In many places exposed property of some kinds is always under its shelter. In some cases it appears to have been worked in the interest of the priests; thus, certain foods—for example, turtle—are always tabu, and cannot be eaten until a portion has been set aside for the gods. There is a purely superstitious use of it, too, in relation to common things, as when a canoe is made tabu that it may go more safely.

The chiefs have a large discretionary power of declaring articles or actions tabu; indeed, their power is unlimited, but they are expected to keep within precedent. In many cases they use it for purely public purposes—thus, when a feast is coming on they lay a tabu upon pigs and nuts, and other articles, that there may be abundance for the feast. And when a scarcity of anything is apprehended they place a temporary tabu on its use. Speaking generally, any article of food—fish, flesh, fowl, grain, or fruit—may be rendered tabu. A coast, a river, a hunting-ground, may be declared tabu; and then there is an end of fishing, and sailing, and hunting, until the chief has withdrawn the prohibition. The tabu is obviously a powerful instrument of government; and the chiefs are very adroit in using it for their own advantage.

When a man has accidentally infringed the tabu against touching a chief, or a relative, or things immediately connected with him, he is freed from the state of tabu by a ceremony called *moë-moë*; this consists in pressing, first the palms, then the back of the hands, to a superior chief's foot, and afterward washing the hands with water. If a man has accidentally eaten food which a relative or chief has left, he goes through a ceremony called *fōta*, which consists in pressing a superior chief's foot against the stomach. Any breach of the laws relating to sacred places must be atoned for by sacrificing to the offended god. A person, when he is tabu, must not use his hands in feeding himself or in working; were he to feed himself, it is believed that he would die; he must be fed by others until the tabu is removed. In many cases the tabu can only be removed by time. Thus, a common person, who has touched a dead chief, remains tabu for ten lunar months; a chief for four or five months, more or less, according to the deceased's superiority over him. In several cases breach of tabu is punished with death; in many, it involves a sort of outlawry—the neighbors of the offender being free to carry off or to destroy his goods.

It is obvious that the effect of breaking a tabu—at any rate, one effect of it—is to produce uncleanness. The offender has done something unholy, accursed; his hands are not clean; if he has not sinned in the last degree he must make atonement or undergo purification. The chief, holding a divinely appointed rank, recognized as a semi-divine person, descended from the gods, is the medium of purification; he has authority to loose as well as to bind. The offense consists in a thing having been done displeasing to the supernatural powers, for which, it is believed, they will not fail to take

vengeance. It is not, in the general case, an offense against any particular god; nor is the punishment of it looked for from one god more than from another. Tabu is certainly older than most of the Polynesian gods; it must have existed for ages before the mythologies took their present shapes; it might have existed before any name for god had become current. It has no connection with fetishism. The Polynesians do not worship natural objects; their belief that certain plants and animals are the shrines of gods would naturally lead to the worship of those; but, in fact, they merely do not eat the plant or animal which is the shrine of their tutelary god. And though this is enforced by a tabu, the tabu is evidently distinct from the belief in the god's connection with the plant or animal; it is only the means of enforcing that belief—being the customary means used to prevent any act which would provoke a god to anger. The origin of tabu seems to be a vague fear of superhuman powers; this has become associated with certain things and acts; thus practically, tabu is a system of divinely appointed restraints—religion, in the primary sense of the word. The religious horror has attached itself—or, through the policy of priests and rulers, has become attached—to every prohibition supported by a strong expediency; which it is apt to do among rude peoples, especially where the prohibition relates to the family, or to the relation of tribesmen to their chief. It must have been through a long process of construction, carried on by the governing classes—the chiefs and the priests—that tabu became the system it now is. The extensive political application of tabu is sufficient evidence that the Polynesian chiefs have been adepts in the art of turning the religious feelings of their countrymen to their own account.

TABULA RASA was a term used by the Romans for a tablet of wax newly smoothed for writing; hence the term has come figuratively to mean leaving the past behind and starting anew. It is also used to denote the condition of the human mind before it has received any impressions.

TACAHOUT is the name given in Algiers by the Arabs to the small gall formed on the tamarisk tree, *tamariscus indica*. Since the discovery of photography these galls have become of considerable importance as a source of gallic acid, of which they contain a large proportion. The French chemists import considerable quantities; and the same gall, under the name of mahee, is imported for the same purpose by British chemists from India.

TA CAMAHAG, or TACAMAHA'CA, a name which, from the number of its applications, has produced considerable confusion in the history of commercial products. No less than four different resins are known under this designation. One, from Mauritius, is obtained from a tree common in India and its islands, called the poon-wood tree, *calophyllum inophyllum*. Another, from South America and the West Indies, is obtained from *zanthoxylum (fagara) octandra*—this is usually called shell tacamahac. A third, also from South America, is yielded by a tree called *iceia tacamahaca*; it is supposed to be the Mexican copal. And the fourth is from North America, and is the produce of the Carolina or tacamahac poplar; it is collected in small quantities, and has only a small value for supposed medicinal properties. The others are chiefly used for varnishes.

TACCA, a genus of plants of a small natural order called *taccaceæ*, nearly allied to *araceæ*. They are large perennials, with tuberous roots. The species are few, and are found in maritime places and woods in the South Sea islands and the warmest parts of Asia and Africa. Some of them (*T. pinnatifida*, etc.) are much cultivated for the sake of their tubers, which are used as an article of food, although they are acrid, and require maceration in water to remove their acidity, on account of which also they are generally eaten with vinegar, or some acid substance. They contain a large quantity of starch, which is wholesome and nutritious, and is imported into Britain as a substitute for West Indian arrow-root. It is known as *Tahiti arrow-root*. Dr. Seemann says that it is an effectual cure for dysentery, which other arrow-root is not. The boiled leaf-stalks of the plants of this genus are also used in China and Cochin-China as an article of food.

TACHE, ALEXANDRE ANTONINE, 1823-94; b. Lower Canada, educated at St. Hyacinthe college, joined himself to the order of the Immaculate Conception, and in 1843 was ordained at the St. Boniface post of the Red River mission. From this point he traveled great distances toward the n.w. and in Manitoba. In 1850 he succeeded Bishop Provencher, to whom he had previously been coadjutor, and in 1871 he became metropolitan. Archbishop Tache was the founder of the St. Boniface theological college, and wrote books on the subject of his missionary labors in the north-west.

TACITURNITY, in the law of Scotland, is a mode of extinguishing an obligation by mere silence, and making no claim upon it within a long time. It is a distinct ground, and embraces a shorter period than the ordinary prescription of limitation (q.v.); for if a creditor never apply for payment or performance of the obligation, a presumption arises either that there never was such an obligation, or that he has abandoned it. Much depends on the circumstances of each case whether such a doctrine is applicable; and, as a general rule, the periods of prescription are adopted as superseding the common law doctrine of taciturnity.

TACITUS, PUBLIUS CORNELIUS, the historian. Of his parentage, or of the time and place of his birth, we can only conjecture that his father was probably Cornelius Tacitus, a Roman eques, who is mentioned as a procurator in Gallia Belgica, and who died in 79. From the emperors Vespasian, Titus, and Domitian he received promotion and other marks of favor; and in 78 he married the daughter of Caius Julius Agricola. In 88, when Domitian was emperor and Tacitus prætor, he assisted as one of the quindecimviri at the celebration of the *Ludi seculares*. Agricola died in Rome in 83, while Tacitus and his wife were absent; and nothing further is known of the historian till 97, when, in the reign of Nerva, he was appointed consul suffectus, succeeding Tacitus Virginius Rufus, whose funeral oration he delivered. Tacitus had already attained distinction as an orator when the younger Pliny was entering upon public life; and both of them were appointed, in Nerva's reign in 99, to conduct the prosecution of Marius, then proconsul of Africa. Tacitus became one of the most intimate friends of Pliny, of whose letters 11 are addressed to him. The time of Tacitus's death is unknown, but he most probably survived Trajan, who died in 117. His extant works are: (1) *Vita Agricolæ*, written after the death of Domitian in 96, and universally admired as a masterpiece of noble sentiment and pregnant epigram. (2) *Historiæ*, written after Nerva's death in 98, and before the *Annales*, and embracing the period from the second consulship of Galba in 68 to the death of Domitian in 96. Only the first four books have reached us in a perfect state, but there must have been many more. (3) *Annales* commencing with the death of Augustus in 14, and closing with the death of Nero in 68. These also have reached us only in an imperfect state. (4) *De Moribus et Populis Germaniæ*. This treatise is trustworthy only as regards those Germans who were best known to the Romans from their proximity to the Rhine. For the provinces beyond that river it has no value, whether geographical or political. (5) *Dialogus de Oratoribus*, if the work of Tacitus at all, must be his earliest. Tacitus is one of the greatest of historians. In love of truth and integrity of purpose he is equalled by few; in conciseness of phrase and power of saying much and implying more in one or two strokes of expression he is rivalled by none. The best editions are those of Orelli and Halm.

TACITUS, MARCUS CLAUDIUS, about 200–76, A.D. ; b. Interamna (modern Terni), in Umbria; elected emperor after the death of Aurelian and an interregnum of seven months. He began his brief reign of 200 days at the advanced age of 75 years; one of the oldest and wealthiest of the senators. He instituted needful reforms in relation to the coinage and the morals of his subjects; being himself of temperate habit, upright, and honest; giving liberally to the state from his private fortune, and living as simply after his accession to the throne as in private life. He claimed descent from the historian Tacitus, whose works he ordered preserved with care in the public libraries, and copies made every year. He favored the restoration of the power of the senate. His victory over the Scythians is recorded on his coins by the inscription “Victoria Gothi” and “Victoria Pontica.” He died at Tyana, some say of a fever, others by assassination.

TACK, the Scottish law-term, synonymous with lease (q.v.).

TACK—TACKING. The *tack* of a sail is the lower windward corner. The *tack* is the rope employed in hauling down that corner to its proper position. The *tack* of a fore-and-aft sail is its lower forward clue or corner; it also designates the rope for hauling down that corner. A ship is said to be on the *starboard* or *port tack* when she is close-hauled, with the wind on the starboard or port side.

Tacking is the practice of beating up against an adverse wind by a zigzag course. If a vessel at A require to sail due n. to B, and if the wind be either n., or from any point n. of the line CAD, it is obvious that the wind will not carry her directly to her destination. As an extreme case, let the wind be n. or dead against her. By setting her sails obliquely, as at A, it will be possible to beat up in the direction AE. If the master consider that at E he has passed sufficiently from his straight course to B, he will then put his helm a-lee, which brings the ship's head straight to the wind, the tacks of the sails being at the same time set free. The after-sails are then smartly braced over to the opposite side, and the ship's head falls off from the wind in an opposite direction to that previously held, until the course is EF. This process is repeated on each side of the line AB, until at length the ship makes her port, B. The length of each tack, as EF, is called a *board*. When the wind is straight ahead, as in the above example, the several boards should obviously be equally on each side of the line AB. If, however, the wind were not so direct, it would be necessary that the boards in one direction should be shorter than those in the other. Sometimes, from the nature of the channel, as an estuary, etc., it is necessary to take a long tack one way, say to starboard, and a very short one to port. This is known as “sailing with a long and a short leg.”

TACKING OF MORTGAGES, in the law of England, is a practice that sometimes occurs in the course of mortgage securities, when one person acquires more than one mortgage over the same estate. Thus, though mortgages, according to the general rule, rank according to the order of date, yet, if a third mortgagee, who became so without notice of a second incumbrance, purchase the first mortgage even after notice of the second mortgage, so as to require a legal title, and if he holds them both in his own right, he can tack the one to the other, and so obtain priority for the third mortgage over the second mortgage. This is on account of an old technicality, scarcely intelligible to other than lawyers.

TACNA, a province, formerly of Peru, but now, provisionally, belonging to Chile. There is some agriculture, and a few mines occur. Area, 8685 sq. m. Pop. '94 (estimated), 32,191. **TACNA**, the capital of the province, is situated on the Tacna river, about lat. 18° s. The Chileans defeated the combined armies of Peru and Bolivia here, May 27, 1880. Pop. '90, 14,000.

TACOMA, city and co. seat of Pierce co., Washington, on Commencement bay, at the s. extremity of Puget sound and at the mouth of the Puyallup river, and on the Northern Pacific railroad; 25 miles n.e. of Olympia. The city has an excellent and commodious harbor; is built principally on a bluff 80 feet above the river and a slope and plateau which reaches an altitude of over 300 feet; and was laid out in 1868, made the Pacific terminus of the Northern Pacific railroad in 1873, became the co. seat in 1880, and became the city of Tacoma by the consolidation of the towns of Old Tacoma and New Tacoma in 1883. The noteworthy buildings and institutions include Puget Sound university (M. E.), Washington college, Annie Wright seminary (P. E.), Pacific university (Luth.), academy of the Visitation (R. C.), Tacoma academy, Public library, Masonic library, Ferry museum of art, Fannie Paddock hospital, St. Joseph's hospital, co. hospital, children's home, seamen's friend society, co. court-house, city hall, railroad office building, chamber of commerce, etc. A few miles s. of the city is the state asylum for the insane. There are Point Defiance and City parks, waterworks owned by the city, electric light and electric street railroad plants, about 65 churches, several national and state banks, and many daily, weekly, monthly, and quarterly periodicals. The U. S. census of 1890 reported for Tacoma 225 manufacturing establishments (since increased to over 300), using a capital of \$7,227,201, and yielding products valued at \$10,433,000. The lumber, coal, grain, and flour interests are large, and the wholesale and jobbing trade extensive. Pop. '90, 26,006.

TACONIC MOUNTAINS, in the co. of Berkshire, w. Mass., and the co. of Bennington, Vt.; running n. and s. on the e. boundary of New York, uniting the Green mountains of w. Massachusetts with the Highlands of the Hudson. They were named from the characteristic strata of the range, a kind of rock (believed to be older than the Silurian system) to which Prof. Emmons gave the name of taconic; attaining a thickness of 30,000 ft. along the Appalachian chain. The formation in various portions consists of slates, sandstones, quartzites, limestones, and iron ore. The highest peak in Vermont is mount Equinox, 2 m. w. of Manchester, 3,872 ft. above the sea; in Massachusetts, mount Greylock, near North Adams, 3535 ft. in altitude.

TACONIC SYSTEM, an extensive series of rocks in the United States, described by Dr. Emmons. They consist of two divisions, the upper having a thickness of 25,000 ft., and containing lower Silurian fossils; and the lower, with 5,000 ft. of thickness, in which, as yet, no fossils have been found, but which is generally considered to be the equivalent of the Cambrian rocks of Britain.

TACTICS (MILITARY). Strategy (q.v.) is the art of manœuvring armies with reference to the objects of the whole campaign—the securing of communications, the cutting off an enemy from his base, throwing him into a position where he must fight at a disadvantage, retreat or surrender. Tactics are the evolutions of an army in the actual presence of an enemy. In the earliest records of battles are those of mere single combats, in which the chiefs, fighting either on foot or in chariots, performed great deeds; and the commonalty, who apparently were without discipline, were held in profound contempt. With the growth of democracy arose the organization of the phalanx (q.v.), the advance of which was irresistible, and its firmness equally so if charged in front. It, however, changed front with great difficulty, was much deranged by broken ground, and failed entirely in a pursuit or if attacked in flank. Far lighter and more mobile was the Roman legion (q.v.). Among Roman tactics was also the admirable intrenchment, which they scarcely ever omitted as an additional source of strength.

Later in the feudal period, this disparity between knight and footman was diminished by the employment of bodies of archers. The adoption of gunpowder for small arms altogether neutralized the superiority of the armored knight. This change brought infantry into the front place in battle and threw cavalry into the status of an auxiliary. The French revolutionary wars tended much toward the development of artillery as a field weapon, and Napoleon employed this terrible weapon to its fullest extent, a practice since followed by the best modern generals. Frederick the Great was considered an innovator for fighting with infantry four deep. During the French war the formation of three deep became general.

Rapid-fire guns, magazine rifles and smokeless powders have given a new phase to tactics. The most extensive maneuvers under modern conditions have been con-

ducted by the Germans, after whose ideas the new tactics of the United States have been more or less modeled, as well as those of almost all the European armies. In the absence of sufficient war experience it is not possible to decide what influence the adoption of the new devices will have on tactics. Experience on the drill ground warrants the conclusion that, if fresh elements have not been introduced into tactics, still the use of the new explosives will have altered in many particulars the importance of existing tactics. The absence of smoke allows of better aim, and consequently better shooting, and allows of the better employment of the quick-firing arm. A further advantage is in the better leading of the firing troops, the clearer observation of the individual, and of the effect of the fire. Unless required for other reasons, the absence of smoke also allows of the pauses formerly considered indispensable during the period of rapid fire being omitted. On the enemy's side, it prevents his recognizing at once the exact situation of the defensive position to be attacked; in other words, the battle-field is rendered far more open to observation. On the other hand, there will be greater uncertainty in determining the enemy's position than formerly, and the difficulties of command will be enhanced by this circumstance; they demand a higher tactical ability and initiative from leaders of all ranks. The difficulty of recognizing the enemy's position will demand a more thorough reconnoissance, and render the command more than formerly dependent on reports of others. See ENGAGEMENT.

INFANTRY TACTICS.—The fire action begins at far greater distances than formerly; fighting in extended order is the only form adopted, not only for the opening and carrying through of the fight, but also for its decision. Movements of bodies of troops in the vicinity of the enemy's fire are more difficult, and columns must no longer be exposed to it. The extension of front of the fighting troops, no less than the distances between the several lines and the reserves, is increased. Direct advance on the enemy, without his fire having been previously beaten down, will expose the troops to destruction. Frontal attacks without simultaneous pressure on the flanks will not secure any decisive advantage. The deployment is carried out earlier, owing to the increased difficulty of reconnoissance. The spade is more than ever an arm in the hands of the infantry, even during the attack. It may, at the same time, be noted that earthworks, such as shelter trenches, etc., must be given a far stronger profile, looking to the increased penetration of the small-bore bullet. It is indispensable to accustom the troops to fighting at night. A further result of the small-bore arm is that, without any addition to the transport, 360 rounds per man, or 90 more than previously, are carried; of these the soldier carries 140 rounds, the remainder being in the ammunition wagons. It is pointed out that regular musketry training and practice grounds are useful for preliminary teaching; but that good training can only be attained by constant exercises on unknown ground with ball cartridge, the other arms being represented. It is distinctly laid down that definite formations cannot be given for the attack—none are to be adopted as normal formations. Pushing forward of troops in front of the general line of defense, for the purpose of offering temporary resistance, is to be avoided.

CAVALRY TACTICS.—The compact drill and formality in the training of former days, which had in view only inspections and parades, is fast disappearing. Riding in different ground of every kind, exercises under service conditions, by day and by night, exercises with units at war strength assimilated, as far as possible, to what would actually occur in war, have taken the place of repeated riding and drills on the exercise ground. With the insured increase of accuracy in the infantry fire, cavalry has been threatened with a new danger, but its effects upon cavalry tactics have been greatly exaggerated. The clearer view of the battle-field in future will put the cavalry commander in a better position for deciding the most favorable moment for attack. The covering clouds of smoke have hitherto hidden both physical losses and moral defeat, and allowed an enemy to withdraw without exposing himself to tactical pursuit. In reconnoitring duties no material modifications of tactics are called for. The most important information will be derived from the cavalry while the enemy is marching, and, consequently, not shooting. Only when occupying fortified positions it will be necessary for scouts to ride with greater care than formerly. It is the almost unanimous opinion in every army at the present time, that there is a great future for cavalry, in spite of the power and precision of modern guns and rifles. It is self-evident that it can no longer attack, with any hope of success, intact infantry—but neither could it in the days of Frederick the Great and of Napoleon. It is recognized, also, that the conditions of success have become more difficult; but so they have in the same degree for other arms. Open ground at great distances is avoided, covered ground sought and utilized, and the attack is only undertaken when the enemy's infantry has been shaken by fire. Only the simplest formations are now considered possible, as success in attack can only be hoped for by that cavalry which goes most directly to its objective, deploys the most rapidly, and strikes its enemy at the sharpest gallop before being struck itself. The action of cavalry in night fighting is not so limited as might at first sight appear. Ziethen's turning movements, the various enterprises in our civil war, and the Russian cavalry in 1877 prove sufficiently that cavalry in large bodies can be brought up to the enemy in the dark unobserved, even in difficult ground. As regards arms, while the Indian troubles necessitate our cavalry being armed with carbines or rifles of some kind, the reintroduction of the lance for continental cavalry is insisted upon. The

entire German cavalry is now armed with it, and the French regiments are experimenting with it. The swimming of cavalry is made an important tactical feature, with special reference to its bearing on patrol work. It is recommended sending equipments and clothing over by rafts or boats, men and horses swimming over more or less bare.

FIELD ARTILLERY TACTICS.—It has been shown that, though there is still a smoke-cloud with smokeless powders, it is so thin that a skirmish line cannot be seen by it beyond 200 to 300 metres, and though visible with artillery fire at the moment of firing, it disperses at once. Artillery therefore gains the advantages of clear sight, both for observing and laying, and of being much less visible to the enemy, provided it is judiciously posted, so as not to show up on the sky line. Artillery engagements must be more thoroughly carried through than before, until the guns of one side or the other are completely crushed. Even after this has been done, the preparation for attack by artillery fire on selected points of the enemy's position must be more complete than formerly, for the fire effect of unshaken infantry armed with the small-bore magazine rifle and with smokeless powder will be enormous. The intervals between batteries and guns have been materially diminished, so that positions for massed batteries are more easily found. The new tactics founded on the above principles omit many of the formations which were formerly in use, and insist on the complete mastery and precise execution of the few simple formations that have been retained. Open division column, as well as half column, is omitted; the only formations for movement are line at full intervals, battery column of single guns, and, under certain circumstances, division columns. Whereas former regulations were based on the peace battery of 4 guns, the new ones deal with the war battery of 6 guns and the 4 wagons forming the first line. The principles of employment in battle have not changed materially. The instruction is new by which, before advancing into the first position for coming into action, a preparatory position is to be taken up where all the preparations for favoring fire being opened rapidly are to be made. As regards the supply of ammunition, that in the limbers is to be left intact as long as possible. The ammunition wagons of the first line move up to the guns without waiting for the order, and are placed to the rear of the right flank gun of each subdivision. The limbers go to a more retired position in the rear and are joined there by the teams of the wagons. To prepare effectually for the infantry attack individual batteries accompany the advance up to the shortest ranges. In the defence a preparatory position is recommended even when the position is artificially prepared. As a rule the whole of the guns are directed in the first instance on the enemy's guns, and are turned on the infantry the moment it begins to advance, regardless of the artillery fire.

FORTRESS WARFARE TACTICS.—The conditions applicable to a field army really apply equally to fortress warfare, which is now closely assimilated to other fighting, by the changes of position of the fortress and siege artillery. The construction of the Schumann armored towers and armored carriages, of a sufficiently portable character to allow of their employment in the field, is another step toward the conversion of operations in the field into a war of position. Their employment will, it is considered, be followed by the presence with an attacking army of a heavier artillery than that now employed. The movable armored towers are designed for quick-firing guns, and they have been found proof against the existing field guns and even shell from 5-inch howitzers. (See GRUSON SHIELDED MOUNTINGS.) In other tactical directions, comprising the organization of special fortress troops, the development of telegraphs and telephones for perfecting the communications, the use of balloons for observation, and the electric light for searching ground at night, considerable progress has been made.

TACTICS (NAVAL). The matter of tactics in the navy is in a partially experimental stage, as no large number of modern vessels has ever been together at any one time for the purpose of developing tactics. There is a "fleet drill book" issued to vessels in commission, which contains the elements for the building up of a tactical signal book. In this work are given general instructions, the school of the ship, school of the section, school of the division or squadron, and general signals. In the make up of the fleet two vessels compose a section, one being the *leader* and the other the *mate*. Four vessels, or two sections, form a division; eight vessels, four sections, or two divisions form a squadron, and two squadrons a fleet. A naval force consisting of more than sixteen vessels will use the number in excess as the nucleus of another fleet organization. The section on the right is number 1, the next to the left number 2, and so on. If there are two divisions in line, one will be termed the right and the other the left; if in column, the leader is the van and the other the rear. During the day, when cruising in formation, the speed of each vessel is indicated by a black or dark-green ball and a small red and blue pennant, the relative position of which indicates the speed of the engines at any time. At night two white signal lanterns will indicate the speed. There is also a white signal lantern at the main mast head, and another one on the taffrail, so screened as to show only astern.

There are six formations, three simple and three compound. The simple formation are line, column, and echelon, and the compound formations are double line, double column, and double echelon. All compound formations can break into simple formations, and all simple formations, with the exception of the echelon, can pass into compound formations. Echelon formation must always pass into line or column before

being formed in any compound manner. Ship evolutions are all comprised in a circle. They consist of the oblique, half-turn, turn, circle, and figure of eight. Section evolutions are composed of simultaneous movements, where each ship makes the same change of course at the same time; successive movements, where one ship changes course and the next ship follows in her wake; the wheel, where the head of the column is changed, but the relative bearing of the ships is maintained; and direct movements, where each ship breaks the formation and forms another by proceeding to her new formation by the shortest route at the quickest speed. Division evolutions are the same as section evolutions, with the exception that the wheel is supplanted by the conversion, and by *isodromes* or paths of equal lengths.

Squadron evolutions are the same as those used in manœuvring a division. When in line the squadron can arrange itself in an indented manner by alternate vessels dropping to the rear. Vessels in case of accident must immediately haul out of the formation. They are *strictly forbidden to stop*. Under all circumstances vessels will sheer out of line to clear the danger. When steaming in column, single or multiple, the vessel next astern of the leader will keep one-half point on the leader's port quarter, if at half distance, and one-eighth point if at double distance. The third vessel, if at half distance, is to take position one-quarter point on the starboard quarter of the *leader*; if at distance, one-eighth point, and if at double distance, one-sixteenth point. The other even-numbered vessels will be astern of number 2, and the odd-numbered ones astern of number 3. Half distance is 1 cable's length or 200 yards; distance, 2 cables', and double distance, 4 cables'. With *ships' boats*, when at tactical drill, distance is 2 boats' lengths, and double distance, 4 boats' lengths. The length of intervals depends a great deal upon the speed of the force. In two columns the interval is generally 800 yards, or 4 cables; in double line the same; but when the speed is greater than 10 knots this interval is increased.

TACUBAYA, a town of Mexico, 3 m. s.w. of the city of Mexico. It has a castle, a military school and the national observatory of Chapultepec, and is of historic interest. Pop. about 12,000.

TADMOR. See PALMYRA.

TADOUSAC, village, watering-place, and co. seat of Saguenay co., Quebec, Canada; on the Saguenay river; 130 miles from Quebec. It was founded in 1599; was formerly the capital of the French settlements and an important fur-trading post; is believed to have contained the first stone and mortar building elected on the American continent; and still preserves the oldest church in Canada, built 1747. It has several hotels and churches, costly villas, and large salmon and other fish interests. Aside from its antiquity, it is most widely known as a delightful summer resort. Pop. '91, village, 700; parish, 2440.

TADPOLE. See FROG.

TAEL, the name commonly given to the Chinese *liang*, a money of account in China, is now (1896) worth from .724 to .806 of an American dollar, varying in different parts of the empire.

TAE-PINGS, the name given to the Chinese rebels who made their appearance in 1850, and (see CHINESE EMPIRE) desolated some of the best cultivated provinces of China. After the war of 1860 it became the interest of the English, French, and American governments to re-establish order in China. The repulse of the rebels at Shanghai in Aug., 1860 had been followed by several engagements between them and the imperialists, in which the Tae-pings were defeated, mainly in consequence of the re-organization of the imperial army by Ward, an American. In the beginning of 1862 the Tae-pings again advanced on Shanghai, and were twice defeated. In that year Ward was killed; and "Ward's force," handed over to an English officer, took the name of Gordon's brigade. Permission was also granted to Capt. Sherard Osborne to organize in England a small fleet of gun-boats, to ascend the Chinese rivers and re-establish order. Gordon's brigade rendered essential service to the imperial government. The rebels were defeated in upward of 16 engagements; and in 1864 almost every important city was taken from them. Capt. Sherard Osborne's expedition was less successful. He found that the jealousy of Chinese officials would not permit him to take the steps necessary to discharge properly the duty he had undertaken, and he therefore threw up his commission, and returned to England. The conduct of the imperial authorities at Su-chow, where a horrible massacre took place, led to the withdrawal of the English military force; but the rebellion had been effectually checked. They were finally dispersed in April, 1865, when they were routed by the imperial army at Kia-ying-chou in Kwan-tung. In the same year, the Nienfei, or marauders of the north, began to be troublesome. This was a marauding expedition, without political significance, which was dispersed in 1866. See PANTHAYS.

TAFFETA (or Taffetas), a term of somewhat general application in silk-mercery. It was formerly applied to all plain silks simply woven by regular alternations of the warp and weft, and is by some writers supposed to be the first kind of silk-weaving known even to the Chinese, from whom it came to us. Modifications have, however, been introduced, by varying the quality of the warp and weft, and by the substitution of various colors for the single one of the original taffeta. It has therefore become a sort of

generic term for *plain silk*, gros de Naples, gros des Indes, shot or chameleon silk, glace, and many others, and even for some combinations of silk, wool, and other materials.

TAFFRAIL, in a ship, is the rail over the heads of the stern-timbers, extending across the stern from one quarter-stanchion to another.

TAFFY. See NATIONAL NICKNAMES.

TA FIA, a name used in the sugar-producing colonies for a kind of rum distilled from molasses. The term is only in general use in French colonies.

TAFT, ALPHONSO, LL.D., was born in Townshend, Vt., in 1810; graduated at Yale College in 1833, and was tutor for two years; was admitted to the bar in New Haven in 1838, but removed to Cincinnati in 1840; gained an extensive practice, and was Republican candidate for Congress, 1856. In 1865 he was made judge of the Superior Court; in 1875 was a candidate for the Republican nomination to the governorship of Ohio; from Mar., 1876-Mar., 1877, he was Secretary of War under President Grant, and from 1882-85 was successively United States Minister to Austria and Russia. He died in California in 1891.

TAGANROG', an important sea-port of Russia, in the gov. of Ekaterinoslav, on the n. shore of the sea of Azov, 18 m. n.w. of the chief mouth of the Don. It was founded by Peter the Great in 1696, was lost to Russia from 1712 till 1774, when it again reverted to the people who founded it, and since that time it has increased in importance yearly. The port of Taganrog is so shallow that large ships cannot approach within half a mile of the quay, and at this distance from shore they load and unload by the help of barges. There is a trade in timber, hemp, wheat, copper, tar and meat. Pop. '97, 51,748.

TAGLIONI, MARIA, 1804-84; a celebrated *danseuse*, b. at Stockholm, of Italian parents, her father (Filippo Taglioni, b. at Milan, 1777) having been successively ballet-master at several opera-houses in different parts of the continent. Mlle. Taglioni made her *debut* in Vienna in 1818. In Paris (1827) she created a perfect *fuoror*, and was at once recognized as the first of ballet-dancers. Her success was equally great at most of the other European capitals, London included. She married and retired from the stage in 1847, and afterwards resided in Italy and in London, where she taught dancing.

TAGUS (Span. *Tajo*), the largest river of the Spanish peninsula, rises on the frontier of New Castile and Aragon, between the Sierra de Albarracin and the Sierra de Molina, about 45 m. n.e. of the city of Cuenca. It first flows n.w. for about 30 m. to its union with the Gallo, at which point it curves to the s.w., and flows in that direction to Toledo, whence it flows w. to Abrantes in Portugal. From Abrantes the river flows s.w., and, passing Lisbon, enters the Atlantic about 10 m. lower down. At the city of Toledo, it breaks through a romantic rocky pass, the walls of which are upward of 200 ft. high. From Villavelha, 18 m. within the Portuguese border, the Tagus is navigable to its mouth, a distance of 115 miles. Above Lisbon, the river widens like an estuary, being in some places 5 m. broad; opposite Lisbon, however, it is only 1 m. broad. The principal affluents are the Jarama, Guadarrama, Alberche, Alagon, and Zezere from the n. and the Guadiela and Rio del Monte from the south. Total length 566 miles.

TAHITI, or OTAHEITE, the chief of the Society islands (q. v.), is 35 m. long, about 120 m. in circumference, and has an area of 401 sq. m. Pop. about 11,200. The chief town is Papiet, which is the capital of the colony.

TAH'LEQUAH, town and capital of the Cherokee nation, Indian Territory; on the Illinois river, 30 miles from its junction with the Arkansas river; 55 m. n.w. of Fort Smith, Ark. It contains Cherokee national male and female seminaries, several primary schools, special schools for negro children, Baptist and Presbyterian mission schools, several churches, and capitol, and has weekly newspapers, printed partly in English and partly in Cherokee, and railroad communication with points in adjoining states by several trunk lines that have been authorized by Congress to enter the territory and nation. Pop. '90, 1200. See INDIAN TERRITORY.

TAIKO SAMA (the name by which Hidéyoshi Toyotomi is best known to English speaking people); 1536-98; b. in the province of Owari, Japan, of humble parents; when still a boy became a retainer of Nobunaga, and rose to be a general of commanding military genius. He avenged the murder of Nobunaga, humbled Satsuma, and reduced the warring clans to submission. Having tranquilized the native empire, he found employment for his restless armies in invading Corea in 1592. He sent Konishi and Kato into the peninsula with 80,000 men, who in a few weeks entered the capital, overran the eight provinces, and met and defeated the hosts of the Chinese sent to succor the Coreans. Having been in 1586 made regent, he retired in favor of his son in 1591, and hence took the title of taiko (*sama* meaning lord, or sir). He greatly patronized art, stimulated by personal favor the porcelain manufacture, and many other industries, encouraged commerce, and internal national improvement. Compelled to act with a high hand between the rival sects of the Jesuits and Dominicans, and to regulate the foreign relations of Japan, he shipped the European friars from the country, and when they re-

turned, had them hanged. The "age of Taiko" is looked upon with admiration by the Japanese, and his life has been many times written in well-illustrated books, his adventures being standard subjects of Japanese decorative art. His last words, like those of Napoleon, were an order to his troops. On his death the victorious soldiers were recalled from Corea. His successor, Iyeyasu, whose genius gave peace to the empire for over 260 years, followed in the main the policy of Taiko.

TAIL, **ESTATE**, is, in English law, an estate given to A and the heirs of his body, or A and the heirs-male of his body, or some other class of heirs less extensive than the class of heirs-at-law. It was anciently a question whether in such a case A, the father, could defeat the right of the children, and break the entail. In England, it was early decided that A could, by a sham process, called a fine or recovery (q.v.) break the entail; while in Scotland it was otherwise, at least since 1685, the Scotch legislature having legalized a mode of securing the entail, and preventing A, or any of his successors, from breaking it. See **ENTAIL**.

TAILOR-BIRD, *Orthotomus*, a genus of birds of the family *sylviadae* (q.v.), with a long graduated tail, the feathers of which are narrow. The species are numerous, natives of the East Indies and of the Indian Archipelago, and haunt cultivated grounds, where they are commonly seen in pairs. Their flight is rapid and undulating, and they seldom ascend above the lower branches of trees. The name *tailor-bird* is derived from the way in which the nest is formed. Two leaves are taken at the extremity of a twig, and are sewed together by their edges, or a large leaf is sewed together; the necessary holes being made by the bill, and vegetable fibers forming the thread. Within the hollow thus made, a quantity of a cottony substance is placed to receive the eggs.

TAILZIE, the ancient term in the law of Scotland to denote a deed creating an entailed estate. See **ENTAIL**.

TAIN, a royal and parliamentary burgh in the county of Ross, Scotland, on the south shore of the Dornoch firth and 24 miles n.n.e. of Inverness. There is no proper harbor. The most interesting building is a small ruined chapel, remarkably rude and simple in architecture, and said to date from the 13th c., and there is also a collegiate church of St. Duthus, founded in 1360, and restored in 1871-76, and an endowed academy incorporated by royal charter. Brewing and iron-founding are carried on. Pop. of royal burgh (1891), 3085.

TAINÉ, **HIPPOLYTE ADOLPHE**, a French critic, was born at Vouziers in Ardennes, April 21, 1823, and studied at Paris, where in 1853 he obtained the diploma of *docteur ès lettres*, for two essays, *De Personi Platonis*, and *Essai sur les Fables de La Fontaine*. They were followed by his *Essai sur Tite Live* (1854), crowned by the French academy; *Les Philosophes Français du dix-neuvième Siècle* (Paris, 1856); *Essais de Critique et d'Histoire* (Paris, 1857); *Histoire de la Littérature Anglaise* (Paris, 1864); *Philosophie de l'Art* (1865; Eng. transl.); *Notes sur l'Angleterre* (1872; Eng. transl.); and others. In the *Littérature Anglaise* (Eng. transl., Edinburgh, 1872), the author surveys and criticises our whole literature from a point of view which is conceived to be rigorously scientific. According to Taine, there are three things to be borne in mind when writing the history of a nation's literature: first, the *race* to which the nation belongs; second, its *position* both geographical and in civilization in the different phases of its literary development; and third, the *period* or duration of these. Under this view, the history of literature assumes the character of a psychological problem. Among Taine's recent works is *Les Origines de la France Contemporaine*, of which the first installment, *L'Ancien Régime*, appeared in 1875 (Eng. transl., 1876). In this the writer gives a graphic account of the social disease that led to the French revolution. A picture of the revolutionary age itself followed in *La Révolution* (vol. i. 1878). He subsequently published *La Conquête Jacobine* (1881); *Le Gouvernement Révolutionnaire* (1885); *Le Régime Moderne* (1891); *Journeys through France* (Eng. translation, 1897). T. was elected a member of the academy in 1878, and died March 5, 1893.

TAIRA, or **HEI**, the name of a celebrated family of Japanese nobles, who with their rivals, the Minamots, kept the empire in turmoil during two centuries. Like the wars of the Roses in England, the war of the red and white banners in Japan ended only when one family was almost annihilated. The Taira house was founded by Takamochi, a great-grandson of the mikado Kuammu who reigned, 782-805. His descendants were for two centuries the military vassals of the emperor. Kiyomori, who became premier, 1167, was virtually ruler of Japan, his daughter being empress, his grandson mikado, and 60 of his relatives holding the highest offices at court, and their lands covering thirty provinces. At the height of their power, the long feud with their rivals, the Minamots, broke out in implacable enmity, 1156. In 1184, after suffering the loss of several bloody battles, driven from Kioto, and from castle to castle, they were slain or imprisoned to the last man, except a few exiles, as the result of the great naval battle of Shimonoséki, and the young mikado Antoku was drowned. In 1870, after 700 years of seclusion, the remnant of the Taira exiles were discovered in a remote mountainous district in Higo, island of Kiushiu.

TAIT, **ARCHIBALD CAMPBELL**, D.D., LL.D.; b. Edinburgh, 1811; educated at the university of Edinburgh and Oxford, becoming afterward a public examiner of the latter; succeeded Dr. Arnold as head-master of Rugby, 1842-50; was made dean of Carlisle, 1850; bishop of London, 1856; archbishop of Canterbury, 1868. He was known as a

prominent opponent of the Tractarians. Among his published works are *The Dangers and Safeguards of Modern Theology*; *The Word of God and the Ground of Faith*; and a volume of sermons. He d. 1882.

TAIT, PETER GUTHRIE, b. England, 1825; graduate of Cambridge, fellow of St. Peter's college; prof. of mathematics in Queen's college, Belfast; prof. of natural philosophy in the university of Edinburgh, 1860. Associated with W. J. Steele, he published *A Treatise on Dynamics of a Particle* (1856); *Elementary Treatise on Natural Philosophy*, with sir Wm. Thomson, fellow of St. Peter's college (1867). He has been associated with Prof. Balfour Stewart in some publications. He published *Thermodynamics* (1868); *Properties of Matter* (1885); *Dynamics* (1895); and other works.

TAI-WAN-FOO, a large city on the s.w. coast of the island of Formosa, with a population (1891) of 135,000, since 1886 known under the name of Tainan. Down to 1885 it was the capital of the island. It is a large straggling town, containing park-like spaces and fine trees, and is surrounded by a high battlemented wall. Canals from the sea run through the level plain that surrounds it, affording means of transportation from the coast. While it was the capital of the Chinese district of Formosa, it was the seat of many important civil and military officials. By the treaty of Shimonoseki in 1895, Formosa was ceded to Japan, but T. still remains the chief city on the island. It is a treaty port and its foreign commerce is extensive, including imports of opium, cottons, woollens, metals, medicines, kerosene oil, rice, flour, etc., and exports of sugar, hemp, camphor, etc. On the coast near by is the port of Takao, which contains a custom house. Tai-Wan, or Tainan, is the seat of Roman Catholic and Evangelical missions, and has telegraph connections with other ports.

TALAVEIRA DE LA REYNA, a t. of Spain, in New Castile, in the modern province of Toledo, is charmingly situated on the Tagus, 75 m. s.w. of Madrid. It is ancient, straggling, dirty, and inconvenient, is surrounded by interesting old walls, and abounds in antique picturesque fragments. It was formerly a flourishing town; but of its manufactures, only those of silk and earthenware are now carried on. Fruits are extensively produced in the vicinity. Here, on July 27 and 28, 1809, sir Arthur Wellesley, with 19,000 English and German troops, and about 34,000 Spaniards, who, however, with very trifling exceptions, were not engaged, defeated upward of 50,000 veteran French troops, under Joseph Bonaparte and marshals Jourdan and Victor. Pop. '87, 10,490.

TALBOT, perhaps originally a name equivalent to blood-hound (q. v.), but afterward applied to a race of hounds, now extinct, or nearly so, which seem to have been kept for show rather than for use. The talbot was of pure white color, with large head, very broad muzzle, long pendulous ears, and rough-hair on the belly. The white St. Hubert dog was either the talbot or a nearly allied breed. The talbot is the badge of the ancient house of Shrewsbury (surname Talbot), and the crest of some of the princely houses of Germany.

TALBOT, a co. in w. Georgia, having the Flint river for its n.e. boundary; drained by Upatoi creek; 360 sq. m.; pop. '90, 13,258, chiefly of American birth, includ. colored. It is intersected by the Talbotton railroad. The surface is hilly, with a large proportion woodland. The soil produces grain and sweet potatoes, and is susceptible of much higher cultivation. Live stock is raised. It has grist mills and cotton gin works. Co. seat, Talbotton.

TALBOT, a co. in e. Maryland, having the Chesapeake bay on the w., the Choptank river on the s. and s.e.; drained also by Tuckahoe creek; 285 sq. m.; pop. '90, 19,736, chiefly of American birth, includ. colored. It is intersected by the Philadelphia, Wilmington, and Baltimore, and other railroads. Co. seat, Easton.

TALBOT, ETHELBERT, the Rt. Rev., was born at Fayette, Mo., in 1848; graduated from Dartmouth college in 1870, and from the Episcopal general theological seminary in New York city in 1873. He became rector of St. James parish at Macon, Mo. In 1887 he was consecrated missionary bishop of Wyoming and Idaho, and in 1891 bishop of Georgia.

TALBOT, JAMES, LL.D., Baron Talbot de Malahide, b. Ireland, 1805; educated at Trinity college, Cambridge; member of parliament for Athlone in the liberal interest, 1832, defeated in 1835. He succeeded to his father's title in 1850; was created peer of the United Kingdom, 1856. He was president of the archæological society of Great Britain and Ireland. He occupied a similar position in relation to the geological and zoological societies of Dublin; and resigned the office of president of the council of the Royal Irish academy, 1869. He is the author of a monograph of the house of Talbot, including the senior branch, the head of which is the earl of Shrewsbury. He d. 1883.

TALBOT, JOHN (1645-1727), was rector of Freetherne, England; chaplain of the *Centurion*, in which the missionaries of the Gospel propagation society came to America, 1702; founder and first rector of St. Mary's church, Burlington, N. J., 1703; for many years a leader of the church of England in the American colonies; consecrated bishop by non-jurors in England, 1722.

TALBOT, JOSEPH CRUIKSHANK, D.D., 1816-83; b. Alexandria, Va.; d. Indianapolis. He was brought up a Quaker, but became an Episcopalian, 1837, and was ordained a minister, 1848. He had a charge at Louisville, Ky., 1848-55, and then at Indianapolis. He became miss. bp. of the northwest, 1860, asst. bp. of Ind., 1865, and bp., 1872.

TALBOT, MATTHEW, b. England in the middle of the 18th century. He published *An Analysis of the Holy Bible, containing the whole of the Old and New Testaments*

collected and arranged systematically in 30 Books, which are subdivided into 285 Chapters and 4,144 Sections. This was republished in the United States by the rev. Dr. Nathaniel West, which was revised under the title of *The New and Complete Analysis of the Holy Bible* by the Rev. Dr. R. D. Hitchcock.

TALBOT, SILAS, 1751-1813; b. Mass.; present at the siege of Boston during the revolutionary war as capt. in a regt. from his state; brev.maj. by congress, 1776, for skillful work in New York harbor against the British fleet. He was wounded at Fort Mifflin, 1777, but remained on the field till the fight was over. In the following year he assisted Gen. Sullivan by transporting the American forces from the main-land to Rhode Island, brevet lieut.col. for the brilliant exploit of capturing the British floating battery *Pigot*, 23 guns, anchored in one of the channels threatening Newport. In 1779 on a cruise off the New England coast, with his prize and the sloop *Argo*, 10 guns, he captured *The Lively*, 12 guns, and 2 letters-of-marque, *The King George*, and *The Dragon*; was made brevet capt. in the navy, 1779, for taking *The Dragon* after a four hours' battle. He was taken in 1780 by the British and imprisoned in the Jersey prison; exchanged the following year. At the close of the war he bought the confiscated property of sir William Johnson near the Mohawk river; was representative to the assembly for several years; member of congress, 1793-94. The frigate *Constitution* (Old Ironsides) was built under his supervision, and in 1799 was his flag-ship during a cruise in the West Indies. He resigned 1801, and passed the rest of his life in New York.

TALBOT, WILLIAM HENRY FOX, celebrated in connection with photography, was the son of William D. Talbot of Locock Abbey, Wilts, and was b. in 1800. He was educated at Harrow, and afterward at Trinity college, Cambridge, where he took his degree with honors, and obtained the junior chancellor's medal in 1821. In the first parliament summoned after the passing of the reform bill, Talbot sat for Chippenham; but scientific investigation being more to his taste, he gave up politics, and devoted himself to the problem of fixing shadows, ignorant at the time of what had been effected in this department by Wedgwood and Davy. Step by step he discovered for himself a method of obtaining and fixing sun-pictures, and on the dissemination of a report as to Daguerre's successes in the same field, secured his just rights by publishing a paper (*Phil. Mag.*, Mar., 1839), in which the successive steps of his investigation and their result were detailed. See PHOTOGRAPHY. This process, by which a *negative* (q.v.) was primarily obtained, was subsequently improved by his invention (patent dated Feb. 8, 1841) of the calotype (q.v.) process. Soon afterward he obtained fresh patents, for an "instantaneous process" (which seems to have well deserved the name, as by it a legible picture was obtained of a printed bill fastened to the rim of a wheel revolving 200 times per second), a mode of "photographic engraving," and a "polyglyptic process." A later invention of his, patented in 1858, was called by him photoglyphic engraving; see PHOTOGRAPHY. In 1842 Talbot obtained the medal of the royal society for his previous discoveries. Latterly he devoted himself to the study of general physics, and to philological and miscellaneous researches. He died Sept. 17, 1877. Among his works are *Hermes, or Classical and Antiquarian Researches*; *Legendary Tales*; *Illustrations of the Antiquity of the Book of Genesis*; and a work on *English Etymologies*.

TALBOTYPE, a photographic process, called by the inventor, Mr. Fox Talbot, the calotype process (q.v.). Its essential features consist in the production in the camera of an image by light on the surface of chemically prepared paper, and this distinguishes it from other paper processes, and by consequence from other photographic processes.

TALC, a mineral allied to mica (q.v.), and, like it, easily separated into very thin flakes, which are transparent and flexible, but not elastic, like those of mica. Talc is composed almost entirely of silica and magnesia, in the proportions of 57-63 silica, and 30-35 magnesia, with 2-6 water. Its colors are silvery white, greenish white, and green. It has a pearly or semi-metallic luster, and is unctuous to the touch, in which it differs from mica. It occurs crystallized, generally in hexagonal tables, or in long prisms: the primary form is a rhomboid. It is also found massive, in beds chiefly in micaceous schists, gneiss, and serpentine.—A kind called *indurated talc*, or *talc slate*, has a curved slaty structure, and is not separable into laminæ, like common talc. It approaches in character to steatite, and is used for similar purposes.

TALCA, a t. in Chile, in the province of Talca, of which it is the capital; pop. 1883, 23,432. It is on the Maule river, about 45 m. n. of Chillan; contains a seminary for priests, and other educational institutions, and has a growing trade.

TALCOTT, ANDREW, b. Conn., in 1797; graduate of West Point, 1818. In 1819 he accompanied gen. Atkinson on an expedition to the upper Missouri and Yellowstone rivers to establish military posts; returned to the e. and in 1821-35 engaged in building defenses at Hampton Roads, Fort Delaware, and other exposed situations. In 1832-36 he was engaged on the boundary line between Ohio and Michigan, and the improvements on the Hudson river; resigned 1836 and became division engineer on the Erie railroad. He was on many important commissions for constructing dry-docks and defenses, and was chief engineer of several railroads. He d. 1883.

TALCOTT, JOHN, about 1630-88; born England; brought to Hartford, Conn., by his father, who became one of the governor's "assistants." The son held the office of treas-

urer of the colony, and is best known as the leader of the expedition which saved Hadley from the attack of 700 Indians, and for his courage in other Indian warfare.

TALEGAL'LA, a genus of gallinaceous birds, of the family *megapodidae*, having a strong, thick, and very short bill, the upper mandible curved and pointed; the head and neck almost quite naked; the wings short and round; the tail rather long, rounded on the sides; the legs strong, feathered a little below the joint of the tibia and tarsus; the tarsi covered with scales in front; the toes long and strong; the claws large and sharp. The species are natives of Australia and New Guinea. The best known is the **BRUSH TURKEY** (*T. lathamii*) of Australia, also known as the **WATTLED TALEGALLA** and the **NEW HOLLAND VULTURE**, the latter name being given to it on account of its naked head and neck, covered in part with fleshy wattles. It is pretty common in New South Wales, inhabiting the most thickly wooded parts. It is a large bird, about the size of a turkey, with blackish-brown plumage. It is shy, and when pursued, endeavors to escape by running through the thickest *brush*, or by leaping to the lowest branches of a tree, from which it ascends higher and higher, branch by branch. It thus avoids the dingoes or native dogs, which, however, often hunt it down on open ground. It is easy game to the sportsman, who finds it roosting under shelter of the branches of trees during the heat of the day, and although several of a flock are shot, the rest keep their place undisturbed. The talegalla is generally seen in small flocks, and they make their nests together, the males heaping up, by means of their feet, mounds of several cartloads of earth and decayed leaves, which are used from year to year, new materials being added every year. The eggs are hatched by the heat of the sun and of the fermenting mound, each egg being separately buried. The parent birds partially uncover them during the day. Nearly a bushel of eggs may sometimes be found in a single heap. The male bird pays great attention to the young after they are hatched, covering them up partially in the mound at night for warmth. The flesh of the talegalla is excellent, and the eggs are also very delicate and eagerly sought after. It is thought that this bird might easily be added to the list of our domestic poultry.

TALENT (Gr. *talanton*, from a root to balance or weigh), a word used by Homer to signify indifferently a balance, and a definite weight of some monetary currency. But the weight of money to which Homer applies the term talent was very different from that to which it was applied in later times. Tradition assigns to Pheidon, king of Argos, the introduction of the talent as a standard of money and weight. The *exact* identity of the Æginetan talent with that known as the Babylonian, and generally employed in the east, points to its true origin. It was in all probability introduced into Greece by the Phenicians, who also introduced a smaller monetary measure and weight, which was by the Greeks known as the Euboic talent. The names Æginetan and Euboic indicate that the talents to which these epithets apply were first used in Ægina and Eubœa; and though, in the east, the larger talent was used for silver, and the smaller for gold, after their introduction into Greece all such distinctive application was soon done away with. The use of the Euboic talent was mostly confined to Athens, Chalcis, and the Chalcidian colonies; while the Æginetan prevailed over the rest of the Greek world. In the 6th c. B.C., Solon introduced at Athens a new talent, which, as the *Attic talent*, succeeded, partly through its superior purity, and partly on account of the greater commercial activity of Athens, in supplanting the other two standards. These several talents were similarly subdivided into 60 minæ, the mina into 100 drachmæ, and the drachma into 6 oboli; and their relative proportions are Æginetan talent: Euboic talent: Attic talent:: 30: 25: 18, both with respect to their values as weights, and as measures of monetary amount. The following are the values as compared with American standards:

| | | AS WEIGHT. | | | | AS MONEY (SILVER). | |
|-----------------|---|-------------------|---|--|--|--------------------|--|
| | | lbs. avoirdupois. | | | | | |
| Æginetan talent | = | 95 | = | | | \$2,030 | |
| Euboic " | = | 79.16 | = | | | 1,692.50 | |
| Attic " | = | 57. | = | | | 1,118.75 | |

But by the same decree of Solon, a new commercial talent, of increased weight, was introduced, but only as a weight for goods, not for money.

TALFOURD, Sir THOMAS NOON, D.C.L., 1795-1854; b. England; studied law; was a member of parliament from 1835-41, and 1847-49, when he received an appointment as judge of the court of common pleas. He advocated in parliament the rights of authors, and introduced in 1837 the copyright act, which with a few alterations was passed in 1842. He wrote the tragedy of *Ion* in 1835, which was performed with great success, and subsequently *The Athenian Captive* (1838); *Glencoe* (1840); and *The Castilian* (1854). He also published *Memoirs and Correspondence of Charles Lamb* (1837); *Final Memorials of Charles Lamb* (1848), and *Vacation Rambles* (1844).

TALATAFERRO, a co. in n.e. Georgia; drained by the Ogeechee and Little rivers; traversed by the Georgia railroad; area, 168 sq. m.; pop. '90, 7291, includ. colored. The surface is irregular. The soil is fairly fertile. The principal productions are corn, cotton, and live stock. Co. seat, Crawfordville.

TALIAFERRO, BENJAMIN, about 1750-1821; b. Va.; a member of Morgan's rifle corps; served at Saratoga, Monmouth, and Savannah, greatly distinguishing himself for coolness and daring on the field. He was aid-de-camp to Gen. Lincoln at Charleston in 1780, and was taken prisoner. In 1784 he removed to Georgia; delegate to the Georgia state constitutional convention, 1798; member of congress, 1799-1802, and filled the office of judge of the superior court, state senator, and president of the state senate.

TALIESIN, a Welsh bard, said to be the son of Hweng, and supposed to have lived in the 6th century. He was called the "chief of the bards," and was, with the two Merlins, the most celebrated among the Christian bards. The *Archæology of Wales* contains some pieces said to be his.

TALIPAT PALM, or Great Fan Palm, *Corypha umbraculifera*, the noblest palm of the East Indies, a native of Ceylon, Malabar, etc. It grows to the height of 60, 70, or even 100 ft., and has a straight cylindrical trunk, crowned with a tuft of enormous palmate plaited leaves, which are divided near the outer margin into numerous segments, and are united to the trunk by spiny leaf-stalks. The leaves are usually about 18 ft. long, exclusive of the leaf-stalk, and 14 ft. broad; a single one being sufficient to protect 15 or 20 men from rain. At the age of 30 or 40 years the tree flowers, and, after ripening fruit, generally dies. It produces a long conical erect spadix, rising to the height of 30 ft. from the midst of its crown of leaves, and dividing into simple alternate branches, the lower of which sometimes extend laterally 20 ft., the whole covered with whitish flowers, and forming a very beautiful and magnificent object. The fruit is very abundant, globose, and about an inch and a half in diameter. The leaves are used for covering houses, for making tents, and for many other purposes. On occasions of ceremony every Singhalese noble is followed by an attendant, who carries above his head a richly ornamented talipat palm leaf, which is capable of being folded up like a fan, and is then not thicker than a man's arm, and wonderfully light. The leaves of this palm are used in Malabar for writing upon, characters being traced upon them with an iron style. They are prepared for this purpose by boiling, drying, damping, rubbing, and pressing. The soft central part of the stem, pounded and made into bread, has often been of great use in times of scarcity. See illus. PALMS, vol. XI., fig. 7.

TALIPES, the scientific name for CLUB-FOOT (q.v.). It is derived from the Latin words *talus*, the heel, and *pes*, the foot.

TALISMAN (Arabic, but supposed to be derived from the Gr. *telesma*, in the sense of celebration of religious ceremonies), a species of charm, consisting of a figure engraved on metal or stone when two planets are in conjunction, or when a star is at its culminating point, and supposed to exert some protective influence over the wearer of it. The terms talisman and amulet (q.v.) are often considered nearly synonymous, but the proper distinctive peculiarity of the former is its astrological character. Talismanic virtues have often been attributed to a peculiarly marked or formed egg, and instances are recorded, by various authors, of eggs hatched with figures of comets or eclipses on them. A species of talisman, which has acquired considerable celebrity is the Abraxas stone (q.v.). A species of talisman at present in use in Asia, is a piece of paper on which the names of the seven sleepers and their dog are inscribed. Pasted on the walls of houses, it is believed to be a protection against ghosts and demons.

TALLADEGA, a co. in n.e. central Alabama; drained by the Coosa river and Choccolocco creek; traversed by the Central of Georgia, the Birmingham and Atlantic, the Louisville and Nashville, and the Southern railroads; area, 784 sq. m.; pop. '90, 29,346, includ. colored. The surface is somewhat hilly, and much of it woodland. The soil is fertile. The principal productions are corn, cotton, wheat, and cattle. Co. seat, Talladega.

TALLADEGA, city and co. seat of Talladega co., Ala.; on the Birmingham and Atlantic, the Louisville and Nashville, and the Southern railroads; 41 miles e. of Birmingham. It is the seat of the State institute for the deaf, the State school for negro deaf-mutes and blind, the State academy for the blind, Talladega college for colored students (Cong.), Isabel female college, and the Presbyterian State orphans' home. The city covers a part of the field on which Gen. Jackson defeated a large force of Creek Indians in 1813. There are gas lights, national banks, waterworks, railroad construction and repair shops, cotton-mill, tannery, iron furnaces, cotton gins, and weekly newspapers. Pop. '90, 2063.

TALLAGE (said by Lord Coke to be from Fr. *tailler*, to share or cut out a part), a name which has been sometimes applied generally to subsidies or taxes of every kind, but which, in its more proper and restricted sense, denotes those taxes to which, under the Anglo-Norman kings, the demesne lands of the crown and all royal towns were subject, which were far more rigorous and irregular than the taxes imposed on the gentry.

TALLAHASSEE, city, capital of Florida, and co. seat of Leon co.; on the Florida Central and Peninsular and the Carrabelle, Tallahassee, and Georgia railroads; 20 miles n. of Appalachee bay, gulf of Mexico. It contains a U. S. government building, the State seminary, the State normal, agricultural, and industrial institute for colored pupils, university and supreme court libraries, several public parks with fountains, gas, street railroad, and artesian water plants, national and state banks, railroad construction and

repair shops, and ice, cigar, and cotton factories. The city is in a farming and fruit-growing region, and has separate churches and schools for whites and negroes, and weekly newspapers. Pop. '90, 2934.

TALLAHATCHEE, a co. in n.w. Mississippi, drained by the Tallahatchee river and several creeks; traversed by the Illinois Central railroad; 635 sq. m.; pop. '90, 14,361, chiefly of American birth, includ. colored. The surface is level and in part swampy; cotton, corn, pork, and cattle are the staples. Co. seat, Charleston.

TALLAPOOSA, a co. in e. Alabama; drained by the Tallapoosa river and Sandy creek; traversed by the Central of Georgia railroad; 795 sq. m.; pop. '90, 25,460, chiefly of American birth, includ. colored. The surface is rough and heavily wooded; cotton, corn, cattle, wheat, and pork are staples. Co. seat, Dadeville.

TALLAPOOSA, a city in Haralson co., Ga.; on the Southern railroad, near the Tallapoosa river; 63 miles w. of Atlanta. It contains a high school, public library, Lithia Springs park, electric light and water plants, hotels, furniture factory, machine works, saw and planing mill, state banks, and several churches. It is in a rich iron, timber, and farming region, and has large interests in iron mining. Pop. '90, 1699.

TALLEYRAND-PERIGORD, CHARLES MAURICE, duc de Prince of Benevento, the most subtle, shrewd, and unprincipled of all modern diplomatists, was b. at Paris, Feb. 13, 1754, of an ancient and distinguished family. His father, CHARLES DANIEL, COMTE DE TALLEYRAND-PERIGORD (b. 1734, d. 1788), was an officer in the French army, and fought all through the seven years' war. CHARLES MAURICE being the eldest son, would in all probability have been designed for a military career had not an accident which he met with when only a year old, rendered him lame for the rest of his life. He was, in consequence, trained for the church, and studied at St. Sulpice, the Sorbonne, and Rheims, but at no period did he betray the least inclination toward a Christian or even a moral life. At the age of 20 he came to Paris and rapidly acquired a reputation for licentiousness. This, however, did not prevent him from obtaining several ecclesiastical benefices, among others the abbacy of St. Denis, in the diocese of Rheims (1775). Appointed *agent général* for the clergy in 1780, a lucrative and important post, which brought him into close connection with the heads of the administrative in France, he now began a serious apprenticeship to public business, without, however, pausing in his career of gallantry. So notorious was his *infâme conduite* (as Mirabeau calls it), that for some years Louis XVI. shrank from conferring on him further ecclesiastical preferment, and it was only on account of his administrative abilities that in 1788 he obtained the bishopric of Autun. When the convocation of the *états-généraux* took place in the year following, he was elected by the clergy of his diocese to represent it, and pronounced in favor of an amalgamation with the *tiers état*, which on June 17 had constituted itself the *assemblée nationale*. His attitude and speeches recommended him to the notice of the popular party, and along with Mounier, Sieyès, and Lally-Tolendal, he was appointed to draw up a constitution for the nation. In this capacity he took an active part in framing the famous declaration of rights, and he was one of those selected (after the destruction of the Bastille) to investigate the causes and peculiar features of the revolutionary movement. It was Talleyrand who proposed (Oct. 10, 1789) the startling measure for the confiscation of church property, arguing that such property did not really belong to the church, but to the nation, and that if the rights of the existing clergy were secured, the nation or its representatives were at liberty to apply it to any purpose they saw fit. On Feb. 13, 1790, a decree for the suppression of religious orders was carried in spite of a vehement opposition, and three days after Talleyrand became president of the assembly. He was one of the first among his order to take the oath to obey the constitution (Dec. 28, 1790), and eagerly urged the clergy of his diocese to follow his example. About the same time he demitted his bishopric of Autun, yet in the following February we read of his consecrating two new bishops (those of Aisne and Finisterre), and although denounced in pontifical briefs as a schismatic, declaring his sincere attachment to the holy see!

Our space does not permit us to describe the important share that Talleyrand had in the financial deliberations of this first period of the revolution, but we must specially note the sagacity he displayed in pointing out the perils attending the issue of assignats, his skill in preparing the way for the adoption of the principle of uniformity in weights and measures, and of an arc of a meridian as the basis of the new metrical system; and, above all, the luminous intelligence shown in the report which he gave in to the assembly (Sept. 10 and 11, 1791) upon public instruction—a report conceived in the liberal and comprehensive spirit of the times, and which was undoubtedly the model followed in all the great changes that subsequently took place when France reorganized her educational system.

In 1792, when the old European despotisms were obviously preparing to coerce the young republic, Talleyrand was sent to London—but not in an official character—to negotiate with the English government. He did not make a favorable impression on George III. or on Pitt. Thrice in that year he essayed to procure a recognition of the republican government, but in vain. The "September massacres" (see SEPTEMBERISTS) made even the staunchest admirers of the revolution shudder. Nothing, therefore, could be done; and Talleyrand would doubtless have returned to France had not a letter of M. de Laporte *intendant* of the civil list of Louis XVI., been discovered, in which Tal-

Talleyrand was noted as a man "disposed to serve" the king. He was immediately placed on the list of *émigrés*, i.e., proscribed (Dec., 1792); and thus his connection with the revolution—fortunately, we believe, for his reputation—was suddenly brought to a close. His career as an exile was (as is generally the case) one of hardship and insignificance. He remained in England till forced to leave by the "alien bill," when he sailed for the United States (Feb., 1794), where he lived for more than a year. After the fall of the terrorists he procured the revocation of his banishment, and in March, 1796, re-entered Paris, having paved the way for a favorable reception by a series of the most adroit and judicious intrigues. We may first note, *en passant*, that in private life he continued to play the rôle of a gay Lothario.

Talleyrand attached himself to the *cercle constitutionnel* that gathered round Mme. de Staël, and so dexterously did he comport himself, that in 1797 he was named minister of foreign affairs in place of C. Delacroix. The rise of Bonaparte was a phenomenon which so penetrating a politician as Talleyrand could not overlook. He cultivated the friendship of the young gen. with a sagacious assiduity, keeping him constantly *au courant*, when away from Paris, of the situation of parties, and became his confidant in those designs, the execution of which resulted in the overthrow of the directory, Brumaire 18 (q.v.), 1799. After this *coup d'état* the subtle finesse of Talleyrand was constantly in requisition. He divined, with a sort of miraculous cleverness, the ideas of Bonaparte, and his whole policy was directed to consolidate the power and authority of his master. In all the diplomatic negotiations that followed the victories of France under the consulate he had the principal part; but Bonaparte thoroughly understood his man, and Talleyrand was quite conscious, as M. Thiers remarks, that he could never impose on his superior. It was he who proposed the kidnapping of the duke d'Enghien (q.v.); and it was by his instructions that the crime was consummated, in spite of the vehement opposition of Josephine, whose honest indignation led her to denounce him as a *maudit boiteux* (cursed cripple). Talleyrand took an active part in preparing the way for the establishment of the empire (1804); and when in the following year England, dreading a French invasion, formed a powerful European coalition against France, it was by the ingenuity of Talleyrand that it was partly broken up. To him, as much as to Napoleon, was owing the organization (1806) of the famous *confederation of the Rhine* (q.v.), which so effectually served the ambitious designs of the emperor. In conducting the negotiations that brought about this confederation he exhibited a truly Machiavellian art. Napoleon was not ungrateful. Talleyrand received the principality of Benevento, which he held as an imperial fief.

When the views of the emperor in regard to Spain became apparent, Talleyrand, who for more than a year had rather fallen into disfavor with Napoleon, came forward with a plan of his own, which, however, was not adopted; but his presence at the interview between Alexander and Napoleon at Erfurt (1808) proved that his influence was as yet undiminished. The ill success of the Spanish war (at first) induced Talleyrand to pronounce against it, and occasioned violent invectives on the side of his sovereign, to which the accomplished cynic (who retained to the last the manners of the old noblesse) only replied by the sarcasm: "*Quel dommage qu'un si grand homme soit si mal élevé!*" (What a misfortune that so great a man should have been so badly educated!). Talleyrand declared in favor of the Austrian marriage; but already the *entente cordiale* between him and Napoleon was ruptured, and he began to look forward to a future in which his own schemes might be hostile to those of the emperor. In a word he was meditating treachery against the power by which he had risen. The victories of Wellington in Spain, and the reverses of Napoleon in Russia and Germany, widened the breach between them, and Talleyrand now only waited the decisive moment in which to ruin the cause of his master. He became the center of a group of Parisian malcontents, whose influence grew with the advance of the allied armies, and finally communications were opened up with the latter and with the Bourbons. It was Talleyrand who dictated to the senate the terms of the deposition of Napoleon; and on the restoration of the Bourbons he became minister of foreign affairs in the first government of Louis XVIII. He was also head of the French legation in the celebrated congress of Vienna; but after the battle of Waterloo a coldness sprang up between him and the Bourbons, and he was relieved of all his offices. Henceforth his career is uninteresting to the student of history. He caballed to regain power, but in vain; and during the reigns of Louis XVIII. and Charles X. he was merely a discontented senator, who never lost an opportunity of injuring the court and the government. After the July Revolution, Louis Philippe employed him as ambassador at the English court, where he contrived to bring about a friendly feeling between the new monarchy and the English government. During the brief remainder of his life nothing externally notable occurred. He died at Valençay, May 17, 1838. Talleyrand was neither a wise, nor a great, nor a good man; but he was infinitely cunning, dexterous, and supple. He had a larger share than most men of what Carlyle calls "vulpine understanding;" and if this world had had nothing but knaves and fools in it, the policy and principles of Talleyrand might have enjoyed a perpetual triumph; but there were forces in the world, both intellectual and moral, of which he took no account, but which took account of him, and, with all his amazing cleverness, dropped him into obscurity and disgrace. Talleyrand was an 18th c. skeptic, over whom the revolution had exercised little influence, while France, and indeed all Europe, had been roused into earnestness by the outburst; and when the ideas of political liberty began their swift, irresistible march,

this *diable boiteux* inevitably lagged behind, and sank out of sight. Talleyrand has left *Mémoires*, which were first published in Dec., 1890. For estimates of his character and policy, see the *Mémoires Politiques* of Lamartine; the *Histoire de Dix Ans* of Louis Blanc, where Talleyrand is rigorously criticised; the *Mémoires* of Guizot, where he is handled with equal severity and justice *Notices et Portraits*, by Mignet; and *Vie Religieuse et Politique de Talleyrand* (Par. 1838), by L. Bastide.

TALLICOO NAH OIL. See CARAPA.

TALLIEN, JEAN LAMBERT, a French revolutionist, was born at Paris in 1769, and first became notable in the beginning of 1792 as the editor of a Jacobin journal, called *L'Ami des Citoyens*, meant to be a friendly rival of Marat's *Ami du Peuple*. From this date his influence over the lower orders of the city steadily increased. He was conspicuous in the events of August 10, and in consequence received the appointment of secretary to the *Commune Insurrectionnelle*. He promoted and afterward defended the massacres of September; and on account of his unscrupulous zeal, was elected to the convention by the department of Seine-et-Oise. There he became the apologist if not the advocate of Marat, denounced the minister Roland, urged with savage emphasis the condemnation of Louis XVI., and was rabidly eager for the ostracism and annihilation of the Girondists (q.v.). Toward the close of 1793 he was sent to Bordeaux, charged with the mission of destroying every trace of the party he hated. His career in the south-west was a mixture of reckless cruelty and shameful vice. To the odious tyrannies of a proconsul he added the luxurious profligacy of a satrap. Fortunately for his countrymen, a passion which he conceived for one of his victims, Madame de Fontenay (*née* Cabarrus), led him to pause in his bloody course. He was called to Paris to account for this singular change in his disposition, satisfied his associates (by paroxysms of patriotic vehemence) that it meant nothing particular, and on March 22, 1794, was chosen president of the convention. Robespierre, however, had found out the sort of man that Tallien was. He hated him for his insincerity and immorality, felt instinctively that he could not be trusted, denounced him severely in the convention, and on June 14 got his name erased from the list of members at the Jacobins. Tallien recognized his danger, and taking advantage of the reaction against the terrorists (though himself one of the basest of the set), already beginning to show itself in France, he dexterously rallied the Dantonists, Hebertists, and others against the rigorous government of Robespierre, St. Just, and Couthon, and brought about the events of the 9th Thermidor (July 27, 1794), which caused the fall of the triumvirate. Tallien now became for a short time one of the most notable and influential men in France; lent his aid to suppress the revolutionary tribunal and the Jacobin club, and drew up the accusations against Carrier, Le Bon, and others of the terrorists! But France could not long tolerate this affectation of virtue on the part of one so infamous; his past life was perpetually held up to scorn and reproach; and finally, on May 20, 1798, he was forced to leave the council of five hundred. Henceforth his career is pitifully insignificant. He accompanied Bonaparte to Egypt as *savant* (?), quarreled with Gen. Menou, and on his return to France, was captured by an English cruiser, and brought to England, where the whig opposition was stupid enough to make a hero of him (1801). Soon after he returned to France, and was contemptuously dismissed as consul to Alicante by Talleyrand, outlived (in utter obscurity) the empire of Napoleon, and died at Paris, Nov. 16, 1820, supported in his last days by the heirs of the monarch for whose death he had inhumanly clamored. His wife (1775-1835) was the daughter of the Spanish minister, Count Cabarrus, and was previously married to the Marquis de Fontenay, with whom she fled from Paris in order to avoid the terrors of the revolution. It was at this time that she was seized by the authorities at Bordeaux, and that Tallien, falling in love with her, procured her release. She was afterward divorced from the marquis and became Tallien's wife after the overthrow of Robespierre. Under the Directory her salon was one of the most brilliant in Paris. While Tallien was absent in Egypt, she was in turn divorced from him and married, in 1805, Count de Caraman, afterwards Prince de Chimay.

TALLMADGE, BENJAMIN, 1754-1835; b. N. Y.; graduated Yale college, 1773; principal of a high school at Wethersfield, Conn.; entered the continental army; became lieut., adjt., and col. of a Connecticut regiment, 1776; surprised and captured 500 tory marauders at Lloyds' Neck, L. I., Sept. 5, 1779, without losing one of his men; planned and led the expedition which took fort George, Oyster bay, and destroyed the British stores on Long Island, 1780; was in some of the principal battles of the war, had charge of Maj. André until the execution of his sentence; was one of Washington's military family, and conducted his secret correspondence; was a successful merchant after the war, and a member of congress, 1801-17. His *Memoirs* were published by his son.

TALLMADGE, FREDERICK AUGUSTUS, 1792-1869; b. Conn.; graduated at Yale college, 1811; studied law at Litchfield, and was there admitted to the bar. He practised with great success in New York, where he held the offices of recorder, superintendent of police, and clerk of the court of appeals. He was a state senator in 1836, and about the same time a judge of the supreme court of errors. At the "Astor place riot" of 1849 he showed great firmness in restoring order.

TALLMADGE, JAMES, LL.D., 1778-1853; b. N. Y.; graduated at Brown university, 1798; practised law, but gave his attention chiefly to agriculture; was for some time private secretary of Governor George Clinton, and in the war of 1812 commanded the troops that defended New York; was a member of congress, 1817-19, and to a bill for the organization of Missouri into a state, he offered an amendment restricting slavery to the region w. of the Mississippi; was a member of legislature, 1824; lieutenant governor, 1826-27. In 1836 he visited Europe, and introduced American machinery into Russia.

TALLOW. See OILS AND FATS.

TALLOW, MINERAL. See MINERAL TALLOW.

TALLOW TREE, the name given in different parts of the world to trees of different kinds which produce a thick oil or vegetable tallow, or a somewhat resinous substance, which, like tallow, is capable of being used for making candles. Tallow tree of Malabar (*vateria indica*) is a very large tree of the natural order *dipterocarpaceæ*. It has leathery leaves of 4 to 10 ft. long, and panicles of white, fragrant flowers, with five petals. The stem is often 16 ft. in circumference. By incisions in the stem, east Indian copal is got; and by boiling its seeds, there is obtained a firm, white, vegetable tallow, which, as it has no unpleasant smell, is particularly suitable for making both candles and soap.—The tallow tree of China (*stillingia sebifera*) belongs to the natural order *euphorbiaceæ*. The capsules are internally divided into three cells, each containing a nearly hemispherical seed, which is covered with a beautifully white vegetable tallow. This the Chinese collect for the manufacture of candles, in order to which, the capsules and seeds are crushed and boiled, and the fat skimmed off while in a melted state. To give it a firmer consistency, wax is added to it, in the proportion of three parts to ten of the vegetable tallow. Linseed oil is also added. The candles made of it are beautifully white. This tree has been introduced into North America, is cultivated about Charleston and Savannah, and is almost naturalized in the maritime parts of Carolina. It presents a very beautiful and remarkable appearance at the approach of winter, when the leaves become bright red, and the pericarps falling off, leave the white seeds suspended by threads.—The name tallow tree is sometimes given in North America to a species of Candleberry (q.v.).—The tallow tree, or BUTTER AND TALLOW TREE of Sierra Leone, is *pentadesma butyracea*, of the natural order *guttifera*, the fruit of which furnishes a solid oil.

TALLY (Fr. *tallier*, to cut), the name given to the notched sticks which, till a recent period, were used in England for keeping accounts in exchequer, answering the double purpose of receipts and public records. They were well seasoned rods of hazel or willow, inscribed on one side with notches indicating the sum for which the tally was an acknowledgment, and on two opposite sides with the same sum in Roman characters, along with the name of the payer and the date of the transaction. Different kinds of notches, differing in breadth, stood for a penny, a shilling, a pound, £20, £100, and £1000. The tally was cleft through the middle by the deputy-chamberlain with knife and mallet, so that each piece contained one of the written sides, and a half of every notch; and the one-half was retained by the payer as his receipt, while the other was preserved in exchequer. At the union of England and Scotland, a store of hazel rods for tallies was sent to Edinburgh, but never made use of. Act. 23, Geo. III. c. 83 abolished the use of tallies in exchequer, and the old tallies were ordered to be destroyed by 4 and 5 Will. IV. c. 15. The destruction of the houses Parliament by fire in 1834 is supposed to have arisen from the over-heating of the flues in which the discarded tallies were being burned.

TALLY-HO, is an English hunting cry used to urge on the hounds when the fox is viewed; the full cry being *ta-a-ly ho! tally ho!! tally ho; go-ne away, go-ne away*, followed by a peculiar scream that no words could imitate. This cry is thought by some authorities to be a corruption of the French expression *à l'ui, ho! ho! à l'ui*, given by Dame Juliana Berners (q.v.) in her *Book of Hunting* as a hunter's cry of the fifteenth century; but its more probable origin may be traced to the Norman hunting cry, *Tailis an*, "to the coppice," used when the game was making for cover. The term "Tally Ho" was first applied to American coaching (see Coaching), in the year 1876. In amateur coaching in England, it is customary to give each coach a name, as "Defiance," "Wonder," "Tally Ho," "Comet," etc. During the year mentioned, Delancey A. Kane, Esq., of New York City, introduced into this country the first amateur coach, running from New York to Pelham, and called it the "Tally Ho." This coach met with great popularity among New Yorkers and gave an impetus to coaching in all parts of the country; thus the term "Tally Ho" came soon to be the general name for all four-horse coaches of this description in America.

TALLYS, THOMAS, composer, b. about 1510-20; d. in London, Nov. 23, 1585. He achieved great proficiency in organ playing, and was organist at Waltham Abbey for many years. About 1542 he was appointed gentleman of the Chapel Royal and served under Henry VIII., Edward VI., and queens Mary and Elizabeth, and was organist to Elizabeth. In 1575-76, he obtained, with William Byrd, letters patent, giving the exclusive right for twenty-one years of printing music and ruled music paper. The first work printed under this patent was their *Cantiones quæ ab argumento Sacre vocantur quinque et sex partium* (London, 1575), containing 34 motets, by Tallys and Byrd, the work being

a beautiful specimen of typography. About this time he composed his famous song of forty parts, originally written to Latin words, but adapted to English about 1630. Tallys's compositions consist of church music, *Order of Daily Service*; *Full Cathedral Service*; *Order for Morning Prayer with the Litany* *Noted*, all of which have been edited in this century, Te Deums, chants, hymns, motets, responses, etc. His MSS. are in Oxford, Cambridge, and the British Museum. He has been called the father of English cathedral music. See *Grove's Dictionary of Music and Musicians*.

TALMA, FRANÇOIS JOSEPH, an eminent French tragedian, was the son of a dentist, and was b. at Paris, Jan. 15, 1763. He made his *début* as an actor in 1787 at the Comédie Française, where he played the part of Séide in *Mahomet*. He achieved considerable success, but apparently not enough to excite any very high anticipations of his future career, and for upward of a year he figured only in secondary characters. The first thing that induced the public to notice him attentively was an innovation in the matter of costume when playing the part of Proculus in the tragedy of *Brutus*. Previously, actors had worn the garb of their own country, and even their own time; and Roman senators stalked about the stage dressed as Parisian "swells" of the 18th century. The absurdity of this fashion forcibly struck Talma, who set himself to amend it, and in the part referred to appeared in the green-room clothed in a Roman toga, greatly to the astonishment of the company, one of whom (Louise Contat) exclaimed: "Good God! look at Talma; how ridiculous he is! Why, he has quite the air of an ancient statue!" The compliment was as exquisite and as just as it was unintentional. Henceforth, a rigorous accuracy in costume became a point with Talma; but his first grand triumph in acting was won, Nov. 4, 1789, when he played Charles IX. in Chenier's piece of that name. During the revolution he was in the zenith of his popularity, and made peculiarly his own such characters as Abdelazis, in *Abdelazis et Zuléma*; Othello; Néron, in *Epicharis et Néron*; Pharan, in *Abufar*; and Egisthe, in *Agamemnon*. Exceedingly arrogant and choleric, he was often at strife, either with the public or with some of his fellow-actors. Talma was a favorite with Napoleon and Louis XVIII. Some of his later characters were among his best, as Marigny, in *Les Templiers*; Leicester, in *Marie Stuart*; Sylla; Oreste in the *Clytemnestre* of Soumet; Leonidas; and Charles VI. He died Oct. 19, 1826.

TALMAGE, THOMAS DE WITT, D.D., b. N. J., 1832; graduated at New York university, 1853; studied theology at New Brunswick, and in 1856 became pastor of the Reformed church in Belleville, N. J.; in 1859 received a call to the Reformed church in Syracuse, N. Y.; and from 1862 to 1869 was settled in Philadelphia. In the latter year began his connection with the Brooklyn Central Presbyterian church, over which he is still pastor. The original "Tabernacle" was erected in 1870, and destroyed by fire in 1872. In 1874 a new building of brick and stone and of Gothic style, with a seating capacity of 4600, was dedicated. This was destroyed by fire in 1889, but rebuilt. Mr. Talmage has published *The Almond Tree in Blossom* (1870); *Crumbs Swept Up* (1870); *Abominations of Modern Society* (1872); *Sports that Kill*; *Every-day Religion*; *From the Pyramids to the Acropolis* (1892); *From Manger to Throne* (1894), and other writings. He was for several years editor of *The Christian at Work*. In 1879 charges of falsehood and dishonorable business conduct were brought against Dr. Talmage before the Brooklyn presbytery. He was acquitted, and the decision was sustained. In 1894, the Tabernacle was for the third time burned, after which Dr. Talmage resigned the pastorate.

TALMUD (from Heb. *lamad*, to learn)—i.e., study, by way of eminence—is the name of the fundamental code of the Jewish civil and canonical law, comprising the Mishna (q.v.) and the Gemara (q.v.), the former as the text, the latter as the commentary and complement. We have spoken under HALACHA and HAGGADA of the gradual development of this "oral," or, chronologically speaking, post-Mosaic code. We have also there mentioned the older collections upon which the Mishna was framed, and finally redacted in the form in which we now possess it. The oldest codification of Halachoth, or single ordinances, is due to the school of Hillel (q.v.). Simon ben Gamaliel the patriarch (166 A.D.) and his school carefully sifted the material thus brought together; and in the following generation, through Jehudah Hanassi (219 A.D.) and his disciples, the work was brought to its close in six portions (Sedarim), 63 treatises (Mesichtoth), and 524 chapters (Perakim), which contain the single Mishnas. A summary of its contents is given under MISHNA. But besides this authoritatively compiled code, there were a number of other law collections, partly anterior to it, and not fully embodied in it, partly arising out of it—as supplements, complements, by-laws, and the like—partly portions of the ancient Midrash (q.v.); partly either private text-books composed by the masters of the academies for their lectures or enlargements of the existing Mishna. All this additional legal material was collected, not rarely together with the dissensions which begot it, under the name of *Boraitoth*, by Chia and his school, in the succeeding generation. Not to be confounded with them, however, are the collections of *Toseftas* or *Great Mishnas*, which, commenced at the time of Jehudah Hanassi himself, and continued after his death by Chija and Hoshaja, embody much of what has been purposely left out in the concise Mishna; that only embraced the final dicta and decisions. Such "additions" we possess now to 52 treatises, forming together 383 perakim, or chapters. All these different sources of the "oral law"—finally redacted before the end of the 3d c., though probably not committed to writing until 550 A.D.—belong to the period of from about 30 B.C. to about 250 A.D. This great mass of legal matter, although apparently calculated to provide for every case, if not for all times, was yet found insufficient. The

dicta of later masters, the decisions of the courts, the discussions on the meaning and purport of special traditions, the attempts at reconciling apparent contradictions in the received material, the amplifications or modifications of certain injunctions rendered necessary by the shifting wants and conditions of the commonwealth—all these and a number of other circumstances made a further codification peremptory.

We must not omit to state here, that this Mishna (Mathneisin), although it contained nothing but what were indigenous laws and institutions, was yet not a little influenced—if the very fact of its redaction was not indeed caused—by the spirit of the times. At Berytus, at Alexandria, at Rome, the legal schools were then in their most vigorous stage of development, and everywhere system and method were being introduced into what till then had been a vast complex of traditional and popular institutions, decrees, and decisions. The Mishna, in all respects, fulfilled the conditions reasonably to be demanded from such a text-book as it was intended to form; it was clear, concise, complete, and systematic, and moreover, composed in as classical a Hebrew as still could be written in those days of decadence of the “sacred language.”

The further development of this supplementary, oral, or second law, in fact, rather an exegesis thereof, together with the discussions raised by apparent contradictions found in the individual enactments of the Mishnic doctors, is called Gemara Discussion, Complement, or, according to another explanation, Doctrine. Whatever the original meaning of the root (*gamar*), it certainly allows of all these significations. This Gemara contains, apart from the Halacha (q.v.), which is generally written in Aramaic, also a vast number of non-legal, chiefly Hebrew, fragments—homiletic matter, tales, gnomes, legends, and the like—called Haggada (q.v.).

There are two Talmuds, the one called the Talmud of the Occidentals, or the “Jerusalem” (Palestine) Talmud, which was closed at Tiberias, and the other, the “Babylonian” Talmud. The first of these now extends over 39 treatises of the Mishna only, although it once existed to the whole of the first five *Sedarim* or portions. Its final redaction—falsely attributed to R. Jahanan (died 279)—probably belongs to the end of the 4th c. A.D.; but the individual academies and masters through whom it received its completion cannot now be fixed with any degree of certainty. There is less discussion and more precision of expression in this than in the second or Babylonian Talmud, emphatically styled “our Talmud,” which was not completed until the end of the 5th c., and which makes use of the former. As the real editor of the Babylonian Talmud, is to be considered Rabbi Ashe, president of the academy of Syra in Babylon (365–427 A.D.). Both the Mishna and the Palestine Gemara had, notwithstanding the brief period that had elapsed since their redaction, suffered greatly, partly by corruptions that had crept into their (unwritten) text through faulty traditions, partly through the new decisions arrived at independently in the different younger schools—of which there flourished many in different parts of the Dispersion—and which were at times contradictory to those arrived at under different circumstances in former academies. To put an end to these disputes, and the general confusion arising out of them, which threatened to end in sheer chaos, R. Ashe, aided by his disciple and friend Abina, or Rabina (abbr. from Rab Abina), commenced the cyclopean task of collecting anew the enormous mass of Halachistic material which by that time had grown up. The method he pursued was simple enough. His disciples met twice a year at Syra, in spring and in autumn. At the spring gathering, he gave out all the paragraphs of one treatise; and the disciples had the task to find out until the autumn meeting what opinions the different schools had pronounced on the special points thereof. He then investigated the whole critically, and put it into shape according to a certain order. This process took him, with the assistance of ten secretaries, no less than thirty years; and another thirty years were spent by him in the revision of the work, with which he proceeded in the same manner as he had done with the compilation itself. The final close of the work, however, is not due, as generally stated, to R. Jose, his successor at the academy (died 475), but to the school of the Saburaim at the end of the 5th century.

The Babylonian Talmud, as now extant, comprises the Gemara to almost the whole of the 2d, 3d, and 4th *Sedarim* (portions), further to the first treatise of the first, and to the first of the last order. The rest, if it ever existed, seems now lost. The whole work is about four times as large as the Jerusalem one, and is 36 treatises, with the commentaries generally added to them in our editions (Rashi and Tosafoth), fill 2,947 folio leaves. The language of the Talmud is, as we said, Aramaic (western and eastern), or “Chaldee,” closely approaching to Syriac. The minor idiomatic differences between the two are easily accounted for by the different time and place; but the additional matter—quotations and fragments from older Midrash and Gemara collections, Haggada, etc.—is, as before stated, principally written in Hebrew.

The masters of the Mishna (Tanaim) and of the Gemara (Amoraim) were followed by the Saburaim (see above). The code of the oral law had come to a close with the second named; and not its development, but rather its proper study, elucidation, and carrying into practice, was the task of the generations of the learned that followed. Apart from this, the Aramaic language itself began to die out as the popular language, and required a further study. The Saburaim no longer dared to contradict, but only opined on the meaning and practicability of certain enactments, and undertook the task of inculcating and popularizing the teachings laid down by their sires: apart from bestowing proper care upon the purity of the text itself, and adding some indispensable glosses. Their activity was at its height in the 8th c., when Karaism (see JEWISH SECTS), which utterly

denied the authority of the Talmud, sprang into existence. Respecting, however, this authority of the Talmud itself, there has never been anything approaching to a canonicity of the code, or of a reception of it as a binding law-book by the whole nation. The great consideration in which it was always held is owing partly to its intrinsic value, and to the fact of its becoming the basis of all further development of Jewish literature (it being undeniably the most trustworthy receptacle of the traditional Jewish law), and partly to a prosecution against the Jews in the Persian empire at the time of Jesdegerd II., Firuz, and Kobad, who closed the schools and academies for a space of nearly 80 years, during which this book was the sole authoritative guide of public conscience, and remained endowed with its importance even when the schools were restored. The best commentaries of the Mishna are by Maimonides and Bartenora; of the Babylonian Talmud by Rashi (q.v.) and the *Tosajists* of France and Germany. An abstract of the Talmud for practical (legal) purposes by Maimonides (q.v.) is called *Mishne Thorah*. The Mishna was first printed at Naples, 1492; the Talmud of Jerusalem at Venice about 1523. The Babylonian Talmud was first published at Venice in 1520. It is generally printed in twelve folios, the text on the single pages being kept uniform with the previous editions, to facilitate the references. No translation of the Gemara has ever been carried further than a few single treatises. The complete Mishna, on the other hand, has been translated repeatedly into Latin, German, Spanish, etc., by Surenhus, Rabe, Jost, and others. We must refrain, in this place, from attempting a general characterization of the Talmud, a work completely *sui generis*. It will assuredly some day, when properly investigated, prove one of the most important records of humanity. Nothing can give even an approximate idea of the immensity of material, historical, geographical, philological, poetical, that lies hidden in its mounds. A contribution to the records of fanaticism may also be found in the "exoteric" history of the Talmud, which was, albeit utterly unknown save by a few garbled extracts, prohibited, confiscated, burned, and generally prosecuted and inveighed against by emperors, popes, theologians, and fanatics generally, from Justinian down almost to our own day, as perhaps no other book has ever been. In our own times, however, its value begins to be recognized by great scholars, not merely as the only source of the knowledge of Judaism, but as the chief source—next to the gospels—even for the history of the origin and early days of Christianity; a notion long ago hinted at by eminent divines like Lightfoot and others. See also JEWS, MIDRASH, MISHNA, HALACHA, HAGGADA; and an important essay in the *Literary Remains* of Em. Deutsch, author of the above article.

TALPIDÆ. See MOLE.

TALUS, a term employed in geology, to designate the sloping heap which accumulates at the base of a rock or precipice, from fragments broken off by the weather, or materials in any way carried over it. The term is also applied to the slope of a wall which diminishes in thickness as it rises.

TAMA, a co. in e. central Iowa; drained by Iowa river and Wolf creek; crossed by the Burlington, Cedar Rapids and Northern, and the Chicago and Northwestern railroads; 720 sq. m.; pop. '90, 21,651, chiefly of American birth, with colored. The surface is in great part prairie; oats, wheat, hay, corn, and pork are the staples. Co. seat, Toledo.

TAMANDUA, a species of the genus *myrmecophaga* or ant-eater (q.v.). The great ant-eater or *M. jubata* of Linnæus, is called tamandua by the Portuguese, but ant-bear by the English and Spaniards. The proper tamandua, so called by the Portuguese of Brazil, is the *M. tamandua* of Cuvier, and is much smaller than the great ant-eater, being about the size of a large common cat, and its head is not so disproportionately long, although it has much resemblance, and the same kind of snout and nostrils. Its length, from the root of the ear to the muzzle, is 5 inches. The greatest circumference of the head, just in front of the ears, is a little over 8 inches. The conformation of the extremities, the number of toes, before and behind, are in all respects the same as the great ant-eater, but it differs in having a prehensile tail, which is covered with short hair, as is also the body, while the great ant-eater has long, shaggy hair, and a bushy tail. The eyes of the tamandua are very small, as are also the round ears. The legs are short and robust. There are several varieties, chiefly distinguished by differences of color. It is a native of the thick forests of tropical America, and is said never to be found on the ground, but exclusively in trees, where it lives upon ants, honey, and it is said, even bees. When going to sleep it hides its muzzle in the fur of its breast, places its belly on a limb, and wraps the whole around with its tail. The female, as is the case with the great ant-eater, has two pectoral mammæ and bears but a single cub at a birth, which she carries about on her shoulders for the first three or four months. It has a strong, disagreeable odor, which is perceptible at a great distance, especially if the animal is irritated. It is called *fourmillier* by the French, and little ant-bear by the English.

TAMAQUA, a borough in Schuylkill co., Pa.; on the Little Schuylkill river, and the Central of New Jersey and the Philadelphia and Reading railroads; 16 m. n.e. of Pottsville, the co. seat. It has a high school, national and state banks, electric lights, water-works supplied by gravity, several foundries and machine shops, powder, flour, and planing mills, and weekly newspapers, and has large interests in important coal mines in the vicinity. Pop. '90, 6054.

TAMARACK. See LARCH.

TAMARA SPICE, a favorite mixture of condiments used by the Italians. It consists of powdered cinnamon, cloves, and coriander seeds in equal parts, and half the same quantity of aniseed and fennel-seed powdered.

TAMARIN, *Midas*, a genus of South American monkeys, small and beautiful, with short muzzle, prominent forehead, long nails, which, except on the hinder thumbs, are formed like claws, the tail longer than the body, not prehensile, and covered with hair so as to resemble the tail of a squirrel. The **SILKY TAMARIN** or **MARAKINA** (*M. rosalia*), is the best known of the genus. It is of a golden yellow color, with fine silky hair, of which it is exceedingly careful, to keep it free from stain. It is often brought to Europe, but is very tender, and seldom lives long. It is a very gentle and playful creature. The hair of the head and neck is elongated, so as to form a wig or mane.

TAMARIND, *Tamarindus Indica*, a beautiful tree, of the natural order *leguminosæ*, suborder *Cæsalpinieæ*, a native of the East Indies, but now very generally cultivated in warm climates. Only one species is known (*T. Indica*), a spreading tree, 30 or 40 ft. high, with alternate pinnate leaves, which have from 12 to 15 pair of small leaflets, and fragrant flowers, with three petals, the pods brown and many-seeded, as thick as a man's finger, and about six in. long. The pods are filled with a pleasant, acidulous, sweet, reddish-black pulp. It is brought to Europe, mixed with seeds and fibers, in the form of a mass resembling jam, from the East and West Indies, and the Levant. Tamarinds are generally preserved by throwing hot syrup on the ripe pulp; but a better method is to put alternate layers of tamarinds and sugar in a stone jar, the color and taste being thus more like those of the fresh pulp. The wood of the tamarind tree, and especially of its roots, is a cabinet wood of much beauty, but of extreme hardness, so that it is wrought with difficulty.—The pods of some other trees of genera allied to *Tamarindus* are filled with a similar pulp, which is used in the same way, as the tamarind plum of India (*dialium Indicum*), and the brown and velvet tamarinds of Sierra Leone, species of *codarium*. See *illus.*, **TEA**, ETC.

On chemical analysis, tamarind pulp is found to contain citric, tartaric, and malic acids; potash, sugar, vegetable jelly, etc. As a salt of copper is a common adulteration, a piece of polished iron (a knife, for example) should be plunged into the pulp, and left in it for an hour, when, if copper be present, it will be deposited on the iron. Tamarind pulp is refrigerant and gently laxative; and in combination with more active remedies, is often employed in the diseases of children. It is used in India as a cooling article of food, and a kind of sherbet is also formed from it; it is also an excellent addition to curries. Tamarind tea is made by infusing tamarinds in boiling water; when cold, it forms an agreeable and cooling drink in inflammatory or febrile disorders. Tamarind whey is prepared by boiling one ounce of tamarinds with a pint of new milk, and straining: this also is an excellent cooling drink in similar cases.

TAMARISK, *Tamarix*, a genus of plants of the natural order *tamaricaceæ*. This order contains rather more than forty known species, all natives of the warmer parts of Europe and Asia, and of Africa, generally growing in arid situations. Some of them are herbaceous, others are shrubs or small trees, with rod-like branches, scale-like leaves, and small flowers in close spikes or racemes. The calyx has four or five segments; the corolla four or five petals; the stamens are hypogynous, equal in number to the petals, or twice as many; the pistil has three styles; the fruit is a one-celled capsule, with numerous hairy seeds. The **COMMON TAMARISK** (*T. Gallica*) grows in sandy places in the countries near the Mediterranean, and has been naturalized in some places on the southern coast of England. It sometimes attains a height of 30 feet. The twigs seem to possess tonic properties, and their medicinal virtues were once in high repute. The ashes of this and some other species of the genus contain much sulphate of soda.—The **ORIENTAL TAMARISK** (*T. orientalis*) is one of the few trees to be seen in the Arabian and African deserts, with the sands of which it seems to struggle more than any other tree or shrub. Its leafless appearance accords with the surrounding desolation. It is called *atlé* or *ethel*, and its wood is used both for fuel and for many economical purposes.—Galls are found on some species in India, and are valued both for medicinal use and for dyeing. *T. mannifera*, perhaps a variety of *T. Gallica*, yields the kind of manna (q.v.) known as Mt. Sinai manna.—The **GERMAN TAMARISK** (*myricaria Germanica*) belongs to another genus of this order.

TAMATAVE, a t. on the e. coast of Madagascar, in lat. 18° 10' s.; long. 49° 28' 30" e. pop. about 15,000. The town is approached through narrow channels formed by coral reefs; is surrounded by palisades, and is the principal port on the island. The dwellings of the natives are of simple construction, with thatched roofs. The principal trade is from the interior; its exports are india rubber, cattle, swine, tobacco, rice, raw silks, mats, woods, baskets, and hides.

TAMAULIPAS, a state in e. Mexico, bounded on the n. by Texas, on the e. by the gulf of Mexico, on the s. by Vera Cruz, and on the w. by Nuevo Leon and San Luis Potosi, drained by the Rio Grande del Norte, the Santander, the Tampico, the Fernando, and other streams; 32,128 sq. m.; pop. '95, 204,206. Capital, Ciudad Victoria.

TAMBERLIK, ENRICO, tenor singer, was born at Rome in 1820, appeared first in Naples in 1841, and visited various parts of Europe, taking leading tenor parts with great success. He also traveled in North and South America. In 1869 he established a manufactory of firearms at Madrid. He died at Paris, March 14 1889.

TAMBOUR (Fr. *tambour*, drum), a frame upon which muslin or other material is stretched for embroidering. The tambour frame originally was made round. Tambour-work was extensively employed, for the decoration of large surfaces of muslin, etc., for curtains and similar purposes; but pattern-weaving has been brought to resemble it so closely, that it is being rapidly superseded.

TAMBOURINE, a very ancient musical instrument of the drum species, much used by the Biscayan and Italian peasants at their festivities, and sometimes introduced into orchestral music where the subject of the piece is connected with a people who use it, as the Basques, gypsies, or peasants of the Abruzzi. It is composed of a piece of parchment, stretched on the top of a hoop furnished with little bells, and is sounded by the hands, fingers, or elbow. When sharply struck by the hand, the tambourine has not much effect, unless used in numbers.

TAMBOV, a province in the s.e. of Great Russia, bounded on the e. by the governments of Penza and Saratov. Area, 25,710 sq. m.; pop. '93, 2,900,646. The southern districts are hilly; the interior is a somewhat elevated plateau, with a gradual slope toward the north. Several lakes are found in the n. of the government and the principal streams are the Tsna, an affluent of the Moksha, and the Moksha, which is itself an affluent of the Oka.

TAMBOV, capital of the government of the same name, on the Tsna, 750 m. s.e. of St. Petersburg. It was founded in 1636 under the czar Michael Theodorovitch, and served as a fortress against Tartar invasion. It is regularly built, and, though the houses are mostly of wood, there are several important institutions, as the college, a theological seminary, a high school for women, the military hospital, etc. Tambov is the seat of considerable manufacturing trade. Pop. '94, 36,243.

TAMBURINI, ANTONIO, b. Italy, 1800; made his début as a singer at Bologna in 1818. He soon gained a high reputation in Italy, and increased it in London and Paris, where he appeared in 1832. He had a powerful baritone voice, and was a good actor. He sang for several seasons in Bellini's *Puritani*, with Grisi, Lablache, and Rubini. His best part was "Don Giovanni." He retired from the stage in 1854, and took up his residence in France. He d. 1876.

TAMERLANE. See **TIMÜR**.

TAMIL' (more properly spelled *Tamir'*, but erroneously written *Tamul*, and erroneously termed by the earlier Europeans "the Malabar") is the name of the language earliest cultivated of all the idioms which the Rev. R. Caldwell designates as Dravidian—this term comprising, according to him, besides the Tamil, the Telugu; Canarese; Malayalam, or Malayârma; Tul'u, or Tul'uva; Toda, or Tuda, or Tudava; Kôta; Gônd; and Khond, or Kund, or Ku. "The Tamil language," this learned author says in his *Comparative Grammar of the Dravidian or South-Indian Family of Languages*, "is spoken throughout the vast plain of the Carnatic, or country below the Ghauts, from Pulicat to cape Comorin, and from the Ghauts, or central mountain-range of southern India, to the bay of Bengal. It is also spoken in the southern part of the Travancore country, on the western side of the Ghauts, from cape Comorin to the neighborhood of Trivandrum; and in the northern and north-western parts of Ceylon, where Tamilians commenced to form settlements prior even to the Christian era, and from whence they have gradually thrust out the Singhalese. All throughout Ceylon, the coolies in the coffee-plantations are Tamilians; the majority of the money-making classes even in Colombo are Tamilians; and ere long the Tamilians will have excluded the Singhalese from almost every office of profit and trust in their own island. The majority of the domestic servants of Europeans, and of the camp-followers in every part of the presidency of Madras being Tamil' people, Tamil' is the prevailing language in all military cantonments in southern India, whatever be the vernacular language of the district; hence, at Cananore, in the Malayâla country; at Bangalore, in the Canarese country; at Bellary, in the Telugu country; and at Secunderabad, where Hindustani may be considered as the vernacular, the language which most frequently meets the ear in the bazaar is the Tamil'. The majority of the *Klings*, or Hindus who are found in Pegu, Penang, Singapore, and other places in the further east, are Tamilians. . . . Including Tamilians resident in military stations and distant colonies, and the Tamil'ian inhabitants of s. Travancore and northern Ceylon . . . the people who speak the Tamil' language may be estimated at *about ten millions*." "Tamil' includes two dialects, the classical and the colloquial, or the ancient and the modern, called respectively the Shen-Tamil' and the Kod'un-Tamil'. The former is the language of poetry and of the ancient inscriptions; it contains fewer words borrowed from the Sanskrit than the colloquial Tamil', and among these chiefly such as express abstract ideas of philosophy, science, religion, and technical terms of the more elegant arts; and, in general, it so considerably differs from the colloquial Tamil' that it is almost unintelligible to the unlearned Tamil'ian. Of all the Indian languages, Tamil' has the most imperfect alphabet. The latter consists of 12 vowels—viz., *a, â, i, î, u, û, e, ê, o, ô, âi, and aû*—and of 18 consonants—viz., *k, ch, t, t, p, R, ng, n, n', n, m, a final*

n, y, r, l, v, r', l'. Compared to the Devanāgarī alphabet of Sanskrit, it is deficient therefore in the vowels *r'i, r'i,* and *l'i,* though it possesses a short *e* and a short *o*, which the Devanāgarī has not; it has but one sound for *k, kh, g, gh;* for *ch, chh, j, jh;* for *t, th, d, dh;* for *p, ph, b, bh.* It is destitute, moreover, of the Sanskrit aspirate *h,* of the Sanskrit sibilants, *s, s',* and *sh,* and of Answara and Visarga. Of combined consonants, which abound in the Devanāgarī alphabet, it admits only the junction of the nasal and the mute, as *n-t, n'-t',* etc.; doubled nasals, as *n-n, m-m,* etc.; doubled surds, as *k-k, ch-ch,* etc.; also *t'k, t'p, Rk, Rch, Rp, yy, ll, vv,* and *nR,* of triple consonants, only *r'nd* and *gnd.* If Sanskrit derivatives, therefore, are Tamilized, various devices are resorted to in order to separate Sanskrit groups of consonants. Thus, Sanskrit *pṛa* becomes Tamil' *pīra;* Sanskrit *kr'ishn'a* becomes Tamil' *kirut't'ina-n* or *kit't'ina-n* (*t't* instead of *sh*).

The earliest history of the Tamil' country is still involved in obscurity. From evidence afforded by the language, Dr. Caldwell has drawn a sketch which would tend to show that the un-Aryanized Tamil'ians had "kings," who dwelt in "fortified houses," and ruled over small "districts of country;" that they had "minstrels," who recited songs at festivals; but that they were without "hereditary priests," without "idols," and ideas of "heaven, hell, soul, or sin;" yet that they acknowledged the existence of God, whom they styled *kō,* or king, and erected to his honor a temple which they called *kō-il,* or God's house. Their chief worship, however, seems to have consisted in bloody sacrifices which they offered to "the devil." Dr. Caldwell further shows that they were acquainted with the ordinary metals, except tin and zinc, and with the planets known to the ancients, except Mercury and Saturn; that they had medicines, hamlets, towns, ships, and practiced the necessary arts of life, such as cotton-weaving and dyeing, though none of the arts of the higher class, as painting, sculpture, etc.; that they knew no astronomy, and were ignorant of philosophy and grammar. The earliest civilization of the Tamil'ians is traditionally attributed to the influence of successive colonies of Brahmans from upper India; and the leader of the first colony is said to have been the Rishi (q.v.) or saint *Agastya,* a personage who plays an important part in Brahmanical legends. He is called the first king of the Pāndiya kingdom, which was situated near the southern extremity of the peninsula; and by the majority of orthodox Hindus he is believed to be still alive, though invisible to ordinary eyes. His era is supposed to belong to the 6th c. B.C.; though, like all other ancient Hindu dates, this date, too, cannot be fixed with any degree of certainty. Whether the Vedic worship (see VEDA) was ever known in the Tamil' country may be matter of doubt; the worship introduced by the Brahmans seems, on the contrary, to have been that based on the incarnations of Vishn'u (q.v.) and S'iva (q.v.), and therefore to belong to an advanced stage of Hinduism. Vaishn'avas, S'aivas, and S'āktas (see INDIA) are the now prevalent sects of the Tamil' country; for the Jainas (q.v.), who flourished in the Pāndiya kingdom, probably from the 8th or 9th c. to the 12th or 13th after Christ, were finally expelled from it; and only a few adherents of this sect may now be met with there.

The oldest Tamil works are, however, those written, or claimed to have been written, by the Jainas; and it is a remarkable fact that at any period of Tamil' literature few Brahmans have contributed anything to it that may be deemed worthy of preservation. The finest composition which Tamil' possesses is the *KuRai'* of Tiruvalluvar, "a work consisting of 1330 distichs or poetical aphorisms, on almost every subject connected with morals and political economy." Dr. Caldwell holds that it is not later than the 9th c. after Christ. A commentary on this work by Parimelaraṅgar is the most classical production which has been written in Tamil' by a Brahman. Besides the *KuRai'*, the following works are said to have received the sanction of the Madura college, which, according to tradition, founded by Vamsa S'ekhara for the cultivation of the Tamil' language and literature, was then probably the most celebrated seat of learning in all Hindustan. Their names are: *Naladiyar, Nanmanikkadikai, Iniyavai Narppatu, Inna Narppatu, Kar Narppatu, Kallavali Narppatu, Tokai, Tirikadukam, Asara Kovai, Pala Moli, Siru Pansa Mulam, Mutu Moli Kanji,* and *Elati.* For a list of other and later works written in Tamil', both mediæval and modern, embracing the topics of religion—Protestant theology, Roman Catholic theology, Hinduism, and books published by Mohammedans—jurisprudence, philosophy, science, arts, literature, philology, geography and history, periodicals and newspapers, see the very useful *Classified Catalogue of Tamil'-printed Books, with Introductory Notices,* compiled by John Murdoch (Madras, 1865); and for learned purposes, the invaluable *Comparative Grammar of the Dravidian or South-Indian Family of Languages,* by Rev. R. Caldwell (Lond., 1856).

TAMMANY, SOCIETY OF. Societies bearing this name in honor of a Delaware chief who died in the latter part of the 18th c., were about that time established in Philadelphia, New York, and other cities; but that organized in New York, May 12, 1789, was the only one that survived and still exists. This society, originally charitable, became diverted to political uses; and, in the hands of the democratic party, grew to be the recognized head of that organization, and to occupy a position in local elections which, ultimately, became apparently impregnable. The connection of many of its members with the "Tweed ring" scandal brought it into disrepute, though it regained much of its former power as the memory of that incident died away. The political struggle of 1880, and again of 1884, sapped its strength, but only for a time.

The Tammany society made its headquarters for many years in a building which occupied the site of the New York Sun building on Park row. It eventually erected its present building in East Fourteenth street, where its meetings take place in a commodious public hall, a smaller room in the structure being used as a German theater. The society has a committee in every assembly district in the city, and a central committee, numbering more than 2000 members. The latter committee controls the nominations, and, to a large extent, the party-vote in the city, and, to some degree, throughout the state.

TAMMERFORS, a t. in the s. of Finland, 250 m. (direct line) w.n.w. of St. Petersburg. It is situated on a rapid which connects two lakes, and affords motive-power to an extensive cotton mill employing a large number of hands. There is also a large flax mill, a fine stocking manufactory, and a paper mill. Pop. (1895), 22,169.

TAMMUZ, a word which occurs once in the Bible—viz., Ezek. viii. 14: "And behold, there sat women weeping for Tammuz." The derivation of the word is as problematic as is the meaning itself. The Vulgate (all the other versions give the word unchanged—thereby confessing the universal ignorance on the subject) has Adonis, and this has indeed been accepted as the most credible explanation of this strange name. It probably means the Phenician god Adonis, whose chief temple and worship was at Byblus, but who at an early period had been introduced into Syria, Cyprus, and Greece, where he was connected with Aphrodite. His festivals were partly the expressions of joy, partly of mourning. In the latter the women gave themselves up to the most unmitigated grief over the "lost Adonis," shaved off their hair, and sacrificed their chastity in his temples. The days of mourning were completed by a solemn burial of an image of the god. This period was followed by a succession of festive and joyful days, in honor of the resurrection of Adonis. The river Adonis (Nahr Ibrahim) (see PHENICIA), which once a year "ran purple to the sea" from the Lebanon, was supposed to be tinged by the blood of the god; and a vessel sent off from Alexandria, and carried by the tide to Byblus, used to inform the mourners by letter that he had been found again. There is no doubt that the different phases of the year, or rather the disappearance and reappearance of the enlivening rays of the sun, and their influence upon all nature (see OSIRIS), were symbolized in these originally poetical, afterward licentious and fanatical rites. The time of the year at which these feasts were celebrated has given rise to much dispute. Most probably, they took place at the summer solstice; and the designation of a Hebrew month as Thamuz—which falls about our August—seems further to favor this opinion.

TAMPA, city and co. seat of Hillsboro co., Fla.; on Tampa bay, the Hillsboro river, and the Florida Central and Peninsular and the Plant system railroads; 30 miles e. of the gulf of Mexico. It is a port of entry, with a fine harbor; is principally engaged in the manufacture of cigars; and has electric lights, electric street railroads, waterworks supplied from springs, national banks, convent of the Holy Names, female seminary, public and private schools, numerous hotels, and daily, weekly, and monthly periodicals. Pop. '90, 5532.

TAMPA BAY, on the w. coast of Florida; an inlet from the gulf of Mexico; 40 m. long, and varying from 6 to 15 m. in width, the n. part being divided into old Tampa and Hillsboro bays. Its entrance is protected by a line of keys, or low islands, and it forms an excellent harbor. It contains a number of small islands, and fish and turtle in great abundance.

TAMPAN, a tick (q. v.) of s. Africa, remarkable for its very poisonous bite, found in Angola and the country southward from it, and described by Livingstone in his *Travels*. It attacks by preference the parts between the fingers or toes. It attains the size of a pea, and when it has satiated itself with blood, is of a dark-blue color, and its skin so tough, that it cannot be burst by squeezing with the fingers. The first effect of the bite is a mingled sensation of pain and itching, which ascends the limb until it reaches the abdomen, and soon causes either violent vomiting and purging, or fever. The tingling sensation lasts for a week.

TAMPICO, or Santa Anna de Tamaulipas, a sea-port of Mexico, in the state of Tamaulipas, on the Panuco, near its mouth in the gulf of Mexico. Its streets are broad and regular, and among other institutions it contains a custom-house. The harbor, formerly dangerous, has been improved so that vessels drawing 24 feet can enter. There are a number of exports and the trade is constantly increasing. Pop. '89, 8000.

TAMPION, the wooden plug placed in the mouth of a piece of ordnance to preserve it from dust and damp.—In naval gunnery the tampion is the wooden bottom for a charge of grape-shot.

TAM-TAM, an Indian musical instrument, resembling the tambourine (q. v.), but larger and more powerful, and oval instead of round. It has been occasionally introduced into orchestral bands.

TAMUS. See BRYONY.

TAMWORTH, a municipal borough and market town, partly in the county of Stafford, partly in that of Warwick, at the confluence of the Tame and Anker, 13 m. n.e. of Birmingham. Of the ancient church the transepts are Norman; the remains of the ancient castle, to which modern additions have been made, are in various styles. Brickmaking,

brewing, dyeing, wool-stapling, and manufactures of tapes and small wares are carried on. There is a bronze statue to the late Sir Robert Peel, erected in 1852. Pop. '91, 6614.

TANAGER, *Tanagra*, a genus of birds of the finch family *fringillidae*, having a conical beak, triangular at the base; the upper mandible notched toward the tip, and its ridge arched. The species are numerous, and the Linnæan genus has been divided into a number of genera, all of which possess the characters just given, and popularly receive the name tanager. All of them are American, and most of them belong to warm regions; but some visit more northern parts of America as birds of passage. Many of the tanagers are birds of very beautiful plumage, and many have good powers of song. The **ORGANIST TANAGER** (*T. or euphonia musica*) is particularly famous for its rich full tones.

TANAKA FUJIMARO, b. in the province of Owari, Japan, about 1843. During the revolution of 1868 was one of the leaders in the cause of progress. He was made vice-minister of education in 1871, and visited America and Europe on an educational mission. On his return to Japan he zealously devoted himself to perfecting a plan of national education by which nearly 3,000,000 Japanese youth of both sexes now attend public-school. In 1876 he again visited the United States to observe the system of education, representing Japan's educational progress at the Centennial exposition. On his return to Japan he established in Tokio a museum of education to which American schools and educators largely contributed. In 1879 he was made minister of justice.

TANANARIVA'. See ANTANANARIVA.

TAN-BALLS. A useful way of utilizing the spent bark of the tanner's yard has been adopted in many parts of England: it consists in pressing the bark into balls or lumps, which harden on drying, and serve for fuel.

TANCRED, a Sicilian prince, the son of Eudes, a Norman baron, and of Emma, the sister of Robert Guiscard (see GUISCARD), was one of the celebrated heroes of the first crusade, and was born after the middle of the 11th c. A.D. Some chroniclers profess to detail the events of his early life, describing him as the most accomplished youth of his time in athletic and military exercises, and of a wisdom far surpassing that of men of mature years, and as a partisan of his cousin Bohemond (q.v.) in the quarrel with their uncle, Roger (q.v.) of Sicily. But the first authentic information respecting him is that he raised a large body of men in Apulia and Calabria, and joined Bohemond, then on his way to the first crusade. The two cousins landed in Epirus, and first one and then the other made their submissions to the Greek emperor, Alexis. Tancred's exploits on the way to Syria; his quarrel with Baldwin for the possession of Tarsus, and his subsequent chivalrous forbearance to, and rescue of, his rival; his wondrous valor before Antioch, where he killed no fewer than 700 infidels, transmitting the heads of 70 to the pope, and receiving a corresponding number of marks of silver in return; his vigorous repulse of the first sortie by the infidels from Jerusalem; his sad and lonely vigil on the mount of Olives; and his gallantry at the storming of the sacred city, are all detailed by the numerous chroniclers of this epoch, in their usual style of extravagant laudation, but with a harmony which speaks favorably for their correct appreciation of his character. He was one of the claimants of the throne of Jerusalem, and was pacified by Godfrey (q.v.), the successful competitor, with the gift of some towns in Palestine, and the principality of Galilee or Tiberias. A brief quarrel with Baldwin, after Godfrey's death, petty combats with the infidels, and occasional wars with the other Christian princes who had settled in Syria and Palestine, occupied the remainder of his life, which was brought to a close at Antioch in 1112. Besides his own principality, he governed that of Antioch, belonging to his cousin Bohemond, from 1100. The fiery and energetic, but at the same time pious, sagacious, and forbearing chief whom the chroniclers present to us has been considerably toned down by Tasso in his *Jerusalemme Liberata*.

TANEY, a co. in s. Missouri, adjoining Arkansas; drained by White river and several creeks; 660 sq.m.; pop. '90, 7973, chiefly of American birth, with colored. The surface is rough, heavily wooded, and moderately fertile; corn, wheat, hay, and pork are the products. Copper and lead are found. Co. seat, Forsyth.

TANEY, ROGER BROOKE, LL.D., 1777-1864; b. Md.; graduated at Dickinson college, Penn., 1795; studied law, and in 1799 was admitted to the bar. He practised in Calvert co. and Frederick, removing to Baltimore in 1822. He was attorney-general of the state in 1827, and in 1831 President Jackson made him attorney-general of the United States. Two years later he was nominated to succeed Duane as secretary of the treasury, but on account of his opposition to the U. S. bank the appointment was not confirmed by the senate. The senate also refused, 1835, to confirm his appointment to the supreme court bench, but two years later he succeeded Chief-Justice Marshall and ably sustained the high reputation for legal profundity and acumen which the supreme court had gained under his immediate predecessor, though the events of the war have overthrown many of the positions then taken. Many most important decisions on constitutional questions were given by him, the most noted being that in the "Dred Scott" case (q.v.). This decision, with the accompanying expression of opinion, had much to do with the discussions and animosity which resulted in war. When in the spring of 1861 application was made to Taney for a writ of *habeas corpus* in the case of a Baltimore citizen who had been arrested by a U. S. officer on a charge of treason, he at once granted it,

denying the right of the president to suspend the *habeas corpus* act. A memoir of Taney's life, in part an autobiography, was published, 1872, by Prof. Samuel Tyler. A bronze statue of him, executed by Rhinehart for the state of Maryland, stands in the city of Annapolis.

TANGANYIKA, a lake of eastern central Africa, lying between lat. 3° and 9° s. Long. of center, 30° e.; surface, 2,710 feet above the sea; length, 400 m.; breadth, from 10 to 50 miles. It was discovered by Speke and Burton in 1858. In 1871 Livingstone confirmed Burton's conclusion, that the Rusi Zi flows into its n. extremity. Cameron surveyed the s. and w. coasts in 1874, and discovered an outlet, the Lukuga, on the w. side. In 1876 Stanley satisfied himself that this channel, which he proved to communicate with the Lualaba or upper Congo, is generally dried up in certain parts of its course. Area, 12,170 sq. m. See Peters, *Deutsch-Ostafrikanische Schutzgebiet* (1895).

TANGENT. See TRIGONOMETRY.

TANGHIN, *Tanghinia venenifera*, or *cerbera tanghin*, a tree of the natural order *apocynaceæ*, a native of Madagascar. The fruit is a drupe, of which the kernel is so deadly a poison, that although not larger than an almond, one kernel is sufficient to destroy twenty people. It was used in Madagascar as an ordeal for the discovery of guilt or innocence, and with the general result of the death of those subjected to it. A little of the powdered kernel was placed on the tongue of the suspected person, and he was obliged to swallow it. Only those recovered whose stomachs quickly rejected the dose. The progress of Christianity and civilization in Madagascar has led to a discontinuance of the use of this ordeal. A similar poison-ordeal is used in some parts of Africa. See ORDEAL and ERYTHROPHLÆUM.

TANGIER, a sea-port of Morocco, on a small bay or inlet of the strait of Gibraltar, 38 m. s.w. of the town of that name. It is a small, ill-built town, situated on two hills; the houses—with the exception of the residences of foreign officials—being, as a rule, miserable edifices, and the streets being narrow and dirty. The town is surrounded by old walls and protected by several forts. It has an extensive shipping trade—the annual value of the entering and clearing cargoes being, according to recent accounts, above \$4,000,000. Tangier was taken by the Portuguese in 1471, ceded to the English in 1662, and held by them for 22 years. Pop. estimated at 20,000.

TANGIPAHOA, a co. in s.e. Louisiana; bounded on the n. by Mississippi, on the s. by lakes Pontchartrain and Maurepas; drained by the Tangipahoa river; traversed by the Chicago, St. Louis and New Orleans railroad; about 780 sq.m.; pop. '90, 12,655, inclu. colored. The surface is flat. The soil is sandy, but fertile in some parts. The principal productions are corn, rice, potatoes, and cotton. Co. seat, Amite City.

TANGLE, the common name of *laminaria digitata* and *l. saccharina*, two species of sea-weed, natives of the British shores, growing on rocks in deep water. The stem is woody, the frond leathery, flat, and without a midrib. The woody stems are sometimes used for knife-handles, the blade being stuck in when the handle is soft, and held fast by its shrinking as it dries. The young stalks form an article of food and are nutritious, owing apparently to the large quantity of gelatinous matter which they secrete. They are also used for feeding cattle. *L. potatorum*, a large species, supplies the aborigines of Australia with instruments, vessels, and food.

TANIS. See ZOAN

TANIS, the Tyrian name of the goddess Astarte (q.v.).

TANISTRY, an ancient Celtic custom of succession, which is generally described as devolving the right to inherit lands or honors on the oldest and worthiest of the blood. The tanist, or righdomna, was the heir-apparent of the monarchy, whom it was the practice to appoint during the lifetime of the sovereign; and there is no doubt that the nearest to the original stock was held to have a preferable claim, as contended by Bruce in his claim to the Scottish throne. The practice of electing a successor was also applied to the inheritance of land, and to succession to ecclesiastical offices.

TANJUR, more commonly written TANJORE, an important town of India, in the presidency of Madras, 180 m. s.s.w. of the city of that name, in the midst of an extensive plain, on one of the branches of the delta of the Kaveri. The town comprises two forts and several suburbs. The former are so connected that they may almost be regarded as one. The smaller of the two is a parallelogram in shape, and 600 yards in extreme length. It is joined on the north to the larger fort, which is circular in shape, and 1100 yards in greatest diameter. The walls of both are lofty and strong, and are surrounded by a ditch cut out of the solid stone. The principal edifices of Tanjur are the great pagoda, esteemed the finest specimen of a pyramidal temple in Hindustan (see INDIAN ARCHITECTURE), and the palace of the rajah. Silks, muslins, and cottons are manufactured. Pop. '91, 54,390. The province of Tanjur, of which the town of the same name is capital, has an area of 3,654 sq.m., and contained, in 1881, 2,000,000 inhabitants.

TANK-WORMS. The mud in Indian tanks has been found to abound in *filaria*, some of which closely resemble the guinea-worm infesting the human body. Although there is no positive evidence, there is extreme probability that these tank-worms are the origia

of the guinea-worm. Dr. Carter, who has had much personal observation of the guinea-worm in India, "argues, and apparently with good reason, *no tank-worm, no guinea-worm*. Persons who bathe in water in which the former is found may expect to have the latter." Mr. Bastian, who has written an excellent paper on the anatomy of the guinea-worm, states that there is an undoubted anatomical relation between it and the tank-worm. The real difficulty in the theory is that these tank-worms are widely diffused, while the guinea-worm is restricted in its localization.

TANNAHILL, ROBERT, was b. on June 3, 1774, at Paisley, where his life was almost entirely passed in the humble occupation of a weaver. Very early he exhibited a taste for poetry, and out of his constant study of the works of Burns, Ferguson, and Ramsay, the ambition was developed in him of emulating these favorite authors. His poetry soon became known, and procured him a local celebrity, which on the publication, in 1807, of a collection of his pieces (*Poems and Songs*; new and larger ed., with a memoir of the author, Glasgow, 1838), was ratified by a wider acceptance. But while his modest fame was extending itself, his life had an abrupt termination. He was found one morning (May 17, 1810) drowned in a canal near Paisley; and there seems almost no reason to doubt that his death was that of the suicide. A morbid melancholy which seems to have been inherent in his nature had gradually been growing upon him, and clouding his life with hopeless gloom. He died at the age of 36.

As a song-writer, Tannahill continues to be remembered; and some few of his best pieces have established themselves as part of the musical repertory of the Scottish people. He has a genuine lyrical gift, much tenderness of sentiment, and a true eye and feeling for the simple effects of nature with which he was familiar. Of the force and passion of Burns, he has nothing; but in grace and sweetness, Burns himself has scarcely perhaps surpassed certain of his happier passages.

TANNER CREEK, a magisterial dist., Norfolk co., Va. Pop. '90, 4966.

TANNHÄUSER, the subject of one of the most attractive German legends of the middle ages, is a knight who, in the course of his travels, comes to Venusberg (q.v.), and enters the cave-palace, to behold the wonders of the lady Venus and her court. After having lived there for some time in every kind of delight, his conscience smites him. Invoking the Virgin Mary, he obtains leave of absence, and makes a pilgrimage to Rome, to pope Urban, to seek, through confession and penance, remission of his sins, and escape from damnation. But the pope, who happens to have a wand in his hand, tells him that he can as little obtain God's mercy as that dry wand can become green again. Thereupon Tannhäuser departs in despair, and returns to the lady Venus in the mountain. Three days afterward, however, the wand begins to sprout and bear green leaves; and the pope immediately sends out messengers to every country, but in vain—Tannhäuser can nowhere be found. Such is the story as told in the popular ballad once common all over Germany, and even beyond it, and sung in the district of Entlibuch as late as the year 1830—the best version of which is in Uhland's *Alte hoch- und niederdeutschen Volkslieder* (Stuttg. 1845). In the preface of the *Heldenbuch*, it is further added, that "the faithful Eckhart"—a character in German heroic legends—sits before the mountain, and warns the people of its dangers. In this shape, the story may be traced as far back as the 14th c.; but the substance of the legend is much older, and goes back to the days of German paganism. Some traditions connect it with the Heselberg or Hørselberg, near Eisenach, in which the lady Holle or Holda (see BERCHTA) held her court, who, on her part again, seems to be identical with Freyja, the Scandinavian Venus. The peculiar mythological meaning of the saga, which has numerous points of contact with many other German traditions, has, however, never yet been thoroughly inquired into. Grimm sees in it a touching portrayal of the regret that lingered in the popular heart after the departing paganism, and of the sternness of the Christian priesthood in regard to it. Compare Kornmann, *Mons Veneris* (Fkf. 1614); Grässe, *Die Sage vom Ritter Tannhäuser* (Dres. and Leip. 1846). In later times, the saga has been put into poetical form, among others by Tieck, and made use of by R. Wagner in an opera. This idea of subterranean palaces in which the king or queen of dwarfs, pigmies, fairies, and so forth, held their court, seems to have been universal. Everywhere, stories are told of men being enticed to enter, and finding it difficult or altogether impossible ever again to obtain their liberty. See THOMAS THE RHYMER. The visit of Ulysses to the isle of Calypso, and that of Circe, appear to be only modifications of the same idea.

About the middle of the 13th c., and contemporary with Pope Urban IV. (Urban IV., 1261-65), there lived in reality in Germany a Bavarian knight named Tannhäuser, who, as Neidhart relates, after returning from the wars, resided as minnesinger (q.v.) at the court of the Austrian duke Frederick II. the quarrelsome. At the duke's death, and after having wasted his substance in dissipation, he resided partly with duke Otto II. of Bavaria, and partly led a wandering life. Tannhäuser has composed fine spirited ballads, which, however, show the decay that had already set in in the minnesinger's art. Tannhäuser's memory was held in high regard by the meistersingers, who also preserved one of his measures; and it is quite possible that this Tannhäuser may have been introduced into popular fiction, and have had his name worked into a myth, in which there is some resemblance to his actual fortunes; in which process, however, that old myth became transformed into the more modern saga. The poems of Tannhäuser are published partly in the second part of the *Minnesinger* (published by Von

der Hagen, Leip. 1838), and part.y in the 6th vol. of Haupt's *Zeitschrift für Deutsches Alterthum* (Leip. 1848).

TANNIC ACID. or **TANNIN.** Under these synonymous terms, chemists include a number of solid non-nitrogenous substances, consisting of carbon, hydrogen, and oxygen, some of which are crystalline, and others amorphous, and possessing no smell, but a well-marked astringent taste. They are soluble in water and alcohol, the solutions being acid, and yielding precipitates with most metallic oxides. A solution of gelatine is also precipitated by a solution of any of the tannic acids, and the gelatinous tissue in raw hides is by an analogous process converted into leather. See **GALLOTANNIC ACID.** None of these acids are volatile; and when exposed to the action of heat, they decompose, and yield the so-called pyro-acids. The persalts of iron yield bluish-black or green precipitates with the tannic acids.

The members of this group are widely diffused throughout the vegetable kingdom. "The bark and leaves of most forest trees, such as the oak, the elm, the willow, the horse-chestnut, and the pine—and of many fruit trees, such as the pear and plum, contain tannin in notable quantity. The wood and bark of many shrubs, such as the sumach and whortleberry, and the roots of the tormentilla and bistort, are also powerfully astringent, owing to the presence of one of the forms of tannin. Coffee and tea, as well as Paraguay tea, likewise contain a modification of this principle. All these bodies, except coffee, precipitate the persalts of iron of a bluish-black color; or, if a free acid be present, the solution assumes a dark-green color."—Miller's *Organic Chemistry*, 2d ed. p. 400. The variety of tannin, or tannic acid, occurring in catechu and kino, produces a green precipitate with the persalts of iron; while that occurring in matricaria, rhatany, and the common nettle, produces a gray precipitate. The principal members of this group are—1. *Gallotannic acid*, or *tannic acid*, $C_{14}H_{10}O_8$ (in the ordinary acceptation of the word), which is mainly obtained from the gall-nut, and has been described in a special article; 2. *Moritanic acid*, $C_{13}H_{10}O_6 + H_2O$, obtained from fustic (*morus tinctoria*); 3. *Quinotannic acid*, $C_{14}H_{10}O_8$, obtained from cinchona bark; 4. *Quercitannic acid*, from oak bark; 5. *Mimotannic acid*, $C_{21}H_{15}O_8$, from catechu; and 6. *Kinotannic acid*, from kino; to which some chemists add a variety occurring in coffee and Paraguay tea, to which the term *caffotannic acid* is given.

TANNING. See **LEATHER.**

TANSY, *Tanacetum*, a genus of plants of the natural order *composite*, sub-order *corymbifera*, allied to *artemisia* (q.v.), and having hemispherical heads of flowers, with the florets all tubular, the receptacle naked, the pappus a slight membranous border. The species are pretty numerous, and are natives of the temperate parts of the old world. COMMON TANSY (*T. vulgare*) is a native of Britain and of continental Europe, growing in fields and by roadsides, river-banks, etc. It has long been generally cultivated in gardens. It is now naturalized, and pretty common in many parts of North America. It is a perennial, from two to four feet high, with great abundance of deep-green, bipinnatifid, inciso-serrate leaves; the flowers in terminal corymbs, yellow, and rather small. The leaves and flowers have a strong aromatic smell and a bitter taste. The young leaves are used for flavoring puddings, cakes, omelets, etc. The plant is also tonic and anthelmintic, and *tansy tea* is an old popular medicine. Some curious old customs still linger in many parts of England connected with the use of *tansy cakes* and *tansy puddings* at Easter, which was originally intended to represent the use of bitter herbs at the paschal feast. In some parishes of the counties of Devon and Dorset the clerk carries round to every house a few white tansy cakes as an Easter offering after divine service on Good Friday, and receives a gratuity from each householder. In former times both ecclesiastics and laics played at ball in the churches for tansy cake at Easter-tide. The highest dignitaries took part in this, and began the ball-playing, which went on during the antiphone, and was accompanied with dancing. After the ball-playing was over, all retired for refreshments; and a gammon of bacon was a standard dish, to signify abhorrence of the Jews. A tansy pudding was an essential part of the feast.—See Chambers's *Book of Days*.

TANTALUM (symb. Ta, new equiv. 182) is a very rare metal, discovered in 1802 by Ekeberg in the Swedish minerals known as tantalite and yttrotantalite. It is so closely allied to columbium or niobium that Wollaston regarded the two metals as identical, a view which was generally adopted till Rose disproved it. As it is of no practical importance, it is unnecessary to enter into any details regarding it.

TANTALUS, a genus of birds of the family *ardeide*, resembling storks in their feet and bill, except that the ridge of the bill is rounded, and its tip gradually curved downward, and slightly notched on each side; a portion of the head, and sometimes of the neck, is bare. The AFRICAN TANTALUS (*T. ibis*) was long regarded as the ibis (q.v.) of the ancient Egyptians, but it is rare in Egypt, and belongs chiefly to Senegal. It is much larger than the true ibis. The AMERICAN TANTALUS, or WOOD IBIS (*T. loculator*), is as large as a stork, but more slender, white, with black quill and tail feathers, the naked skin of the head and neck black. It is found both in North and in South America. In the United States it chiefly inhabits the swampy districts of the south.

TANTALUS, a character noted in Greek mythology for the punishment he suffered in the lower world. He is said to have been the son of Zeus by Pluto, and some accounts describe him as king of Argos or Corinth. Various reasons are assigned for his undergoing the severe punishment which he did, the most common being that he divulged the divine counsels of Zeus, which the latter had communicated to him as secrets. In the lower world he was afflicted with an insatiable thirst, and had to stand up to the chin in a lake, the waters of which receded whenever he tried to drink of them. Clusters of fruit hung over his head, which eluded his grasp whenever he endeavored to reach them, his mind at the same time being kept in a state of constant terror lest a huge rock, suspended above his head, and ever threatening to fall, should crush him. Tantalus, or rather the punishment which he suffered, has supplied the English language with the very significant verb, "tantalize." Tantalus was the father of Pelops, Broteas, and Niobe.

TANTIVY is a hunting term denoting "at full speed." It is formed to resemble in sound the note from a hunting-horn. "To ride *tantivy*" is to ride at full speed.

TANTRA (from the Sanskrit *tan*, to believe, to have faith in; hence, literally, an instrument or means of faith) is a name of the sacred works of the worshippers of the female energy of the god S'iva. See S'ÂKTAS. A Tantra is said to comprise five subjects—the creation and destruction of the world, the worship of the gods, the attainment of all objects, magical rites for the acquirement of six superhuman faculties, and four modes of union with spirit by meditation. A variety of other subjects, however, are introduced into many of them, while some are limited to a single topic, as the mode of breathing in certain rites, the language of birds, beasts, etc. They always assume the form of a dialogue between S'iva and his wife, in one of her many forms, but mostly as *Umâ* (q.v.), or *Pârvatî*, in which the goddess questions the god as to the mode of performing various ceremonies, and the *mantras*, or prayers and incantations to be used in them. These he explains at length, and under solemn cautions that they involve a great mystery, on no account whatever to be divulged to the profane. The efficacy of these *mantras* is deemed to be all-powerful, and, according to some Tantras, that of the faith in these revelations of S'iva so great, as to free a believer from the consequences of even the most atrocious sins. The followers of the Tantras profess to consider them as a fifth Veda (q.v.), and attribute to them equal antiquity and superior authority. Though such an antiquity, or even one approaching the age of the four Vedas, is entirely imaginary, the question of their date is nevertheless involved in obscurity. As Tantras are referred to in some of the *Purân'as* (q.v.), they must have preceded these; but as, on the one hand, the age of the *Purân'as* themselves is merely conjectural, and as there probably existed older *Purân'as* than those we possess now; and, on the other hand, as there might likewise have been older Tantras, from which the works now so called were compiled, the circumstance that Tantras are quoted by some *Purân'as* would not throw much light on the date of those now extant. It seems more significant, however, that the oldest known author of a glossary of classical words, Amarasinha (see *lexicography*, under SANSKRIT LITERATURE), should have omitted from among the meanings he assigns to the word *tantra*, that of "a sacred book;" whereas the later commentators on his work do not fail to supply this omission, which certainly would have been an extraordinary one had Tantras existed at the time of Amarasinha. If, then, this negative evidence has the value which it seems to have, the Tantras would, at all events, be later than the first centuries of the Christian era. The works of this class are very numerous, and it is to be regretted that Sanskrit philology, which has already investigated, more or less profoundly, nearly all the branches of Sanskrit literature, should hitherto have almost entirely neglected this particular branch of it.

TANTUM ERGO, the hymn uniformly sung in the Roman Catholic church at benediction with the holy sacrament. These are the first words of the penultimate strophe of the hymn *Pange Lingua*. The *Tantum Ergo* is the most popular of all the eucharistic hymns of the Roman Catholic church.

TANZIMAT, or TANSIMAT, the plural of the Arab word *tansim*, generally signifies "regulations," but in a special sense denotes the organic laws established by the Hattî-Sherif of Gulhane, in accordance with which the administration of the Turkish empire is carried on. These organic laws, the first attempt at constitutional government in Turkey, were published by Sultan Abdul-Medjid in 1844, and treat of—1st, the political organization of the empire, and the powers and jurisdiction of the chief officials and higher courts; 2^d, administration and finance; 3^d, justice; 4th, military affairs. But the tanzimat was a dead letter, or nearly so, except in connection with the army; so that on Sept. 7, 1854, the sultan found it necessary to publish a new ordinance, in which the complete carrying out of the tanzimat in all respects was commanded; and a commission was appointed to see that this was done.

TAORMINA (anc. *Tauromenium*), a t. on the e. coast of Sicily, province of Messina, situated on a narrow ledge of rock, 900 ft. above the sea, about 31 m. s.w. of Messina. It consists mainly of a single street, more than a mile in length, is surrounded by a Saracenic wall, has numerous convents and churches, many picturesque palaces and mansions built in the middle ages, and numerous relics of antiquity, among

which are very fine supulchers, an aqueduct, tessellated pavements, remains of a "Nau-machia" and of a theater, the last reckoned one of the most splendid ruins in Sicily, and commanding a view of almost unparalleled magnificence. Taormina has some trade in wine and hemp, and a pop. '81 of 2388.

Ancient *Tauromenium* was built after the destruction of Sicilian Naxos in 403 B.C., but the exact date is uncertain. It rapidly attained prosperity; but its history during the Greek and Roman period presents no striking features.

TAOS, a co. in northern New Mexico, bordering Colorado and having the main chain of the Rocky Mountains for its eastern boundary; 2300 sq.m.; pop. '90 9868. It is drained by the Rio Grande. Co. seat, Taos.

TAPAJOS, an important river of Brazil, and an affluent of the Amazon, is formed by confluence of the Arinos and the Juruena, both of which rise in the south of the province of Matto Grosso. After a northward course of upward of 1100 m. in length the Tapajos falls into the Amazon, about 20 m. below the town of Santarem. In lat. about 7°30' s., it has a fall of 30 ft.; but the interruptions to the navigation, which is said to reach to within a short distance of the source of the river, are few. A portage of only 18 m. separates the upper waters of the Tapajos from those of the Paraguay.

TAPE-GRASS, a popular name for *vallisneria spiralis*. See VALLISNERIA.

TAPESTRY (Fr. *tapisserie*), a kind of carpet-work for decorating walls and furniture. The art of working tapestry is extremely ancient, but we have little information about it until the time of the Saracens, who revived it, and brought it into notice. They, in all probability, only used tapestry as drapery or curtains for the courts of their houses; its use as a covering for walls seems to have been an invention of the Flemings previous to 1606, at which date it was introduced into France by Henry IV., who engaged Flemish artists to teach it. At that period, so generally was its origin attributed to the Saracens that it was called *Sarrazinois*. The oldest piece in existence is that described under the name of the BAYEUX TAPESTRY (q.v.). At first, the Saracenic tapestries were only ornamented with flowers and geometric figures; but the Flemings aimed higher, and sought to enrich them with historic subjects of the highest order; and so important did this art become, that the most eminent masters in painting, from Raphael downward, bestowed their greatest efforts upon cartoons to serve as copies for the tapestry-workers, of which the celebrated Raphael cartoons, formerly at Hampton Court, now in a gallery especially designed for them in the Kensington museum, are illustrations (see CARTOON). After its first introduction into France by Henry IV. at the beginning of the 17th century, the art of making tapestry does not appear to have made much progress until the middle of that century, when a small establishment founded by the brothers Canaye on the premises formerly occupied by Jean Gobelins, a dyer of wool, was commenced, and was afterward carried on by a Dutchman named Gluck and his assistants with such success, that it was suggested by Colbert, the minister of Louis XIV., that it should be taken under the king's patronage; in consequence of which the establishment was bought, and constituted a royal manufactory in 1667, under the management of M. Lebrun, who was the first director. A royal carpet-manufactory had been previously established in 1615; this was called La Savonnerie, from the previous use of the buildings for the manufacture of soap. The Savonnerie and the Gobelins were both carried on with great spirit by successive sovereigns, and were formed into one establishment in 1826, when the works of the Savonnerie were removed to the Gobelins, where this most interesting work is now carried to great perfection, and also at a minor establishment at Beauvais, in the department of Oise, where it is, however, worked in a different style and manner. At the Gobelins, a series of threads are arranged vertically in a frame like the warp of a loom, and the workman stands behind the frame, the pattern being placed behind him for reference. To produce the design, he has a number of wooden needles threaded with wool and silk of the colors required, and these are passed through the upright warp-threads, and brought back, so that each thread becomes covered with the necessary color; and such is the extreme nicety with which this is done, and such the delicacy and multiplicity of the shades of color employed, that but little difference can be detected between the tapestry picture and the painting from which it was copied. At Beauvais, the warp is placed horizontally, and the workman stands over it; this renders it necessary to cut off the ends on the upper surface, which is avoided in the other plan of working from behind. The Beauvais is, however, a style intermediate between tapestry and carpet-work, and the roughness of surface so produced has a good effect. Much fine tapestry was employed in former times in decorating the palaces and mansions of Great Britain, in many of which it is still seen in great beauty. The modern works of the Gobelins were distributed as presents by the late imperial government of France. They are not produced in great numbers, and are of great money value. The number of artists employed is about 120.

TAPEWORM is a word popularly used in a vague sense to designate any worm of the group *cestoidea* (see CESTOID WORMS). According to Dr. Cobbold, upward of 250 distinct forms of cestoid worms have been described, of which probably somewhat less than 200 may be regarded as really good species. These he divides into the three families of (1) *taniadae*, or true tapeworms; (2) *bothriocephalidae*, and (3) *tetrarhynchidae*. For the natural

history of the tapeworms generally, we must refer to the article CESTOID WORMS. We will here only remind the reader of the following points necessary for the due understanding of this article, and that every tapeworm passes through several distinct phases during its life-history. "In the ordinary colonial or tapeworm condition," says Dr. Cobbold, "it has been termed the *strobila* (Van Beneden). The separate joints of which the strobila is composed are denominated *proglottides*, or zooids. The anterior segment forms the *head*, and remains barren, those of the neck and front part of the body being sexually immature during the process of strobile-formation. The mature proglottides at the caudal end are capable of realizing an independent existence, and the eggs which they contain develop the six-hooked embryos, or *proscolices* (Van Beneden), in their interior. These latter become metamorphosed into *scolices* or nurses, representing the well-known cysticercal state, which, in its sterile or aborted condition, forms the common *hydatid*."—*Entozoa*, p. 105. During the greater part of their existence, the tapeworms are parasitic animals, the mature proglottides and eggs being free only during a comparatively short interval. They are mostly restricted in their distribution to the vertebrate animals, comparatively few of the invertebrates (excepting the cuttle-fish) appearing to harbor them in their adult condition, although the tapeworm larvæ, nurses, or *scolices* probably abound in various invertebrate groups. In the human body, no less than ten species of tapeworm occur, viz., eight *true tapeworms*, and two species of *bothriocephalus*; and as four distinct species have been found in the Barbary ape, it is obvious that errors of diet, due to civilization, are not the cause of these parasites. Among the animals with which we are most familiar, the species are plentiful in the common dog (and in true carnivora generally), in rats, and mice. The typical ruminants are almost constantly invested both by mature and immature forms; while the larger pachyderms, and solidungulates (the horse, ass, etc.), harbor only a few adult forms; but only larvæ appear to be known in swine. These worms appear to be as abundant in granivorous birds as in carnivorous hawks, owls, etc. In the water-birds generally, the adult worms are very abundant, their larvæ existing in the food of such birds, in fishes, mollusks, etc. In reptiles, these worms are extremely rare, although other parasitic worms abound; while in fishes they are very abundant both in the adult and larval forms.

The *teniada*, or *true tapeworms*, may be distinguished from the other families of the order *cestoidea* (cestoids or tapeworms in the popular sense) "by the possession of a small distinct head, furnished with four simple oval or round suckorial disks (suckers), and commonly also with a more or less strongly pronounced rostellum (proboscis) placed at the summit in the median line. This prominence, when largely developed, becomes retractile, and when not in use, is lodged within a flask-shaped cavity, lined by a sheath, and supplied with special muscles; it is also very frequently armed with a single or double crown of horny chitinous hooks, there being occasionally as many as five or six separate circular rows of these organs. Attention to the number, relative size, and disposition of the hooks is often sufficient to determine the particular species. In nearly all cases the reproductive orifices are situated at or near the margins of the joints which are bisexual."—Cobbold, *op. cit.*, p. 109. The eight true tapeworms occurring in man are—(1) *Tenia solium*, Linnaeus; (2) *T. mediocanellata*, Küchenmeister; (3) *T. acanthotrias*, Weinland; (4) *T. flavopuncta*, Weinland; (5) *T. nana*, Von Siebold; (6) *T. elliptica*, Batsch; (7) *T. marginata*, Batsch; (8) *T. echinococcus*, Von Siebold.

The common *tapeworm*, *tenia solium*, derives its Linnæan title from the idea that it is always a solitary worm. Although this is commonly, it is not by any means always the case: Küchenmeister has several times found two or three together, and cases are recorded in which 30 and even 40 worms have been expelled from one patient. The full-grown tapeworm (strobila) has been known from the earliest times, and is described by Hippocrates, Aristotle, and Pliny; but its organization and mode of development have only been properly understood during the last few years. The segments of which it is composed vary in size, and number from 800 to 1000, the earlier immature ones being extremely narrow, and the sexually mature joints commencing at about the 450th segment. From 10 to 35 ft. may be regarded as representing its ordinary length; its breadth at about the widest part being one-third of an inch. The head, which is seldom seen in the tapeworms exhibited in our museums, although the evacuation of the head with the rest of the worm is not very rare, is very small and globular (about the size of a pin's head), with black pigment ingrained in it. On examining it with a low magnifying power, it displays four circular sucking disks, in front of which is a conical proboscis, armed with a double crown of hooks, from 23 to 28 in each circular row. The head is succeeded by a very narrow neck, nearly half an inch in length, which is continued into the anterior or sexually immature part of the body, in which traces of segmentation first appear in the form of fine transverse lines, which are gradually replaced by visible joints. These joints or segments represent the body, and each mature segment contains both male and female organs of generation; and in addition to these structures, the entire series of joints is traversed by a set of vascular canals constituting the so-called aquiferous system, which consists of two main channels, one passing down on either side of the worm, and both being connected by transverse vessels, which occur singly at one end of every joint. It is only in the alimentary canal of man or some other animal that a tapeworm of any kind can attain to sexual maturity; and in all of these the eggs are fecundated before being discharged. The expulsion of the eggs may take place in any of

the following ways: First, the mature segments separate from each other, and passing out of the body, either with the ordinary evacuation of the bowels or independently, become decomposed, and set free the enclosed eggs. The single joints thus discharged undergo violent contraction after being expelled, which led to their being formerly mistaken for a distinct species of worm, to which the title *vermes cucurbitini* was applied, from their resemblance to a pumpkin seed. There is a figure in Aitken's *Medicine*, 3d ed. vol. i. p. 815, showing the joints of a *tænia mediocanellata* (which will be presently described) of the natural size, in various stages of contraction; and on examining the recently discharged excrement of a constipated dog, the same phenomenon may be very frequently observed. Secondly, the eggs may be discharged through the genital pore by pressure from any cause. It is only thus that we can account for the occasional (but very rare) coexistence of a *cysticercus cellulosa* (the embryo of the worm) and an adult tapeworm in the intestinal canal of the human subject—an association which constitutes one of the most serious dangers which the matured worm can inflict upon its host, and one of the strongest indications for its removal. Thirdly and lastly, the mature joints sometimes appear to undergo disintegration within the intestine, and to liberate the eggs; but the conditions under which this disintegration occurs are unknown. In reference to the ultimate fate of the embryos *in ovo*, that are liberated in the intestinal canal, Dr. Cobbold has informed the author of this article in a private communication, that, in his opinion, they do not migrate in the living host, except when by regurgitation they occasionally get into the stomach, when, after their shells have been dissolved by the gastric juice, the young organisms commence their wanderings. The mature segments are usually expelled from the human bowel at the rate of six or eight a day. Their vitality is prolonged by moisture, which favors the distribution of the liberated eggs over grass and other vegetables, or in water, which may be used as food or drink by animals. For a full description of the eggs we must refer to Dr. Cobbold's work. It is sufficient here to remark that, in their mature condition, they "present a globular figure, and are easily recognized by their remarkably thick shell, which surrounds the six-hooked embryo. They present an average diameter of $\frac{1}{16}$ of an inch, the shell itself measuring about $\frac{1}{100}$ of an inch in thickness. After a while, by accident as it were, a pig coming in the way of these embryos, or of the proglottides, is liable to swallow them along with matters taken in as food. The embryos, immediately on their being transferred to the digestive canal of the pig, escape from the egg-shells, and bore their way through the living tissues of the animal, and having lodged themselves in the fatty part of the flesh, they there rest to await their further transformations or destiny. The animal thus infected becomes measled, its flesh constituting the so-called measly pork. In this situation the embryos drop their hooks, and become transformed into the *cysticercus cellulosa*. A portion of this measled meat being eaten by ourselves, either in a raw or imperfectly cooked condition, transfers the cysticercus to our own alimentary canal, in which locality the cysticercus attaches itself to the wall of the human intestine, and having secured a good anchorage, begins to grow at the lower or caudal extremity, producing numerous joints or buds to form the strobila or tapeworm colony."—Cobbold, *Entozoa*, p. 221. In its fully mature stage the *measle* presents the appearance of an elliptical hydatid, varying in size from that of a pea to that of a small kidney-bean, the average diameter being one-third of an inch. On dissecting or breaking up a measle it will be seen that the great vesicular portion constitutes the bladder-like caudal extremity of the cysticercus, while the head, neck, and body can be drawn out so as to exhibit a vermiform character.

In the article GENERATIONS, ALTERNATION OF, it was stated that the group of phenomena included in that term would be further illustrated in the history of the tapeworm. From what has been already shown it appears that "we have a simple alternation of generation in which the immediate product of the proglottis (or sexually matured zooid individual) is a six-hooked brood; by metamorphosis the latter becomes transformed into the cysticercus, having a head with four suckers, and a double crown of hooks; and by gemmation the latter gives rise to a whole colony (strobila) of individuals, the greater part of which are destined to become sexually mature—zooid individuals or proglottides. It will be observed, therefore, that the product of a single ovum is, in the first instance, a single non-sexual embryo; in the second phase, it becomes a non-sexual cysticercus (these two phases together constituting the protozooid); in the third change it gives off, by budding, numerous gemmules, most of them destined to be sexually mature individuals (or deuterozooids), in this way resembling their original parents. The relation and nature of these developmental changes may be further simplified by placing the various life phases in a tabulated form as follows:

- | | |
|----------------------------------------------------------------------|---------------|
| (a.) Egg in all stages. | } Protozooid. |
| (b.) Six-hooked embryo = proscœlex. | |
| (c.) Resting larvæ, or <i>cysticercus (telæ) cellulosa</i> (scolex). | |
| (d.) Immature tapeworm. | |
| (e.) Strobila, or sexually mature <i>tænia solium</i> . | |
| (f.) Proglottis (cucurbitinus) = free segment = deuterozooid. | |

—Cobbold, *Entozoa*, pp. 221, 222.

How long a tapeworm can naturally exist in an intestinal canal is not known; but there is doubtless a period at which the parasite spontaneously separates from the intes-

tinal mucous membrane of its host—a period probably coinciding with the shedding and non-renewal of the cirlet of hooks. When this separation occurs, the whole length of the worm is expelled, in the same manner as if the parasite had been first killed by the administration of a vermifuge medicine. From this history of the structure and life-history of this organism, which applies with slight difference in minor points to all other tapeworms, we proceed to describe the injurious effects which the worm in its adult and larval stages produces on man, and the precautions which should be taken to prevent its entrance into the system; while the discussion of the means of expelling it when it has once found a lodgment in the intestinal canal, will be postponed to the article on VERMIFUGES.

The common tapeworm may cause disease, and even death, by its aggressions, either in the adult or in the larval stage of its existence. A mature tapeworm in the intestinal canal may give rise to a series of anomalous symptoms, including “vertigo, noises in the ears, impairment of sight, itching of the nose and anus, salivation, dyspepsia and loss of appetite, colic, pains over the epigastrium and in different parts of the abdomen, palpitation, syncope, the sensation of weight in the abdomen, pains and lassitude in the limbs, and emaciation.”—Davaine *Traité des Entozoaires*, etc., p. 103. Many cases are on record in which hysterical fits, chorea, epilepsy, convulsions of various kinds, and even mania, have been induced by the irritation excited by this parasite, and have ceased at once on its removal. But distressing as these symptomatic phenomena may be, their injurious effects are trifling as compared with the troubles which follow the deposition and growth of the larval form within the body, especially when the cysticerci find a home in the more important vital organs. There are at least a hundred cases on record in which the cysticercus has caused death by its development within the human brain. In the present state of our knowledge, it is impossible to diagnose these cases; and even if a correct diagnosis were possible, nothing could be done in the way of treatment. Epilepsy, with or without mania or imbecility, is commonly, but not invariably present in these cases. “Cysticerci,” says Dr. Cobbold, “may develop themselves in almost any situation in the human body, but they occur most frequently in the subcutaneous areolar, and inter-muscular connective tissue; next, most commonly in the brain and eye, and lastly, in the substance of the heart and other viscera of the trunk.”—*Entozoa*, p. 226. The adult form of the worm enters the system as the cysticercus of mealy pork, and to eat raw or underdone mealy pork is an almost certain means of introducing this parasite into the body. It is satisfactory to know that the temperature of boiling water is quite sufficient to destroy the vitality of the measles; and that in ordinary salted pork, and in hams, they are destroyed by the action of the salt in the one case, and of the combined salt and smoke in the other. Sausages, into which it is to be feared mealy pork too often find its way, are rendered safe if they are cooked till no pink, raw-like, fleshy look can be seen in their center. Butchers are especially liable to tapeworm, in consequence of their touching and cutting mealy pork, and then accidentally transferring the cysticercus by the hand, or even by the knife to the mouth, and by indiscriminately using the same knife for various meats, both butchers and cooks may readily disseminate the infection over various articles of food. The larval worm may gain access into the human body by our swallowing the mature eggs of the tapeworm. Those who, as students of this department of natural history, handle fresh tapeworms, are perhaps especially liable to this misfortune; but, says Dr. Cobbold, “our neighbors, who devour choice salads, also run a certain amount of risk, not only as regards this entozoon, but as respects several others. The vegetables may be manured with night-soil containing myriads of tapeworm eggs, or they may be watered with fluid filth into which these eggs have been cast. In such cases, one or more tapeworm ova may be transferred to our digestive organs, unless the vegetables are carefully cleansed before they appear on the table. In the same way, one perceives how fallen fruits, all sorts of edible plants, as well as pond, canal, or even river water, procured from the neighborhood of human habitations, are liable to harbor the embryos capable of gaining an entrance to our bodies. It thus becomes evident also how one individual suffering from tapeworm may infect a whole neighborhood, rendering the swine mealy, these animals in their turn spreading the disease far and wide.” Such a person may also prove dangerous—even fatal to his neighbors directly (without the intervention of a pig), by ejecting mature proglottides, from which thousands of eggs may escape, some of which may readily come in contact with human food or drink, make their way into the stomach, and from thence get into the circulation, and finally to the brain, where they cause convulsions and death. The most remarkable case on record of what may be termed a *mealy man*, is one described, in 1864, by Delore, in the *Gazette Méd. de Paris*, and quoted by Dr. Cobbold. He died at the age of 77, from pulmonary catarrh, old age, and fractured neck of the thigh-bone; and on examining his body after death, no less than 2,000 cysticerci were found, of which 111 occurred in the nervous centers.

The tapeworm that ranks next in importance to the *tania solium* is the *tania medio-canellata*, which was first established as a distinct species by Küchenmeister only a few years ago. It exceeds the *T. solium* both as regards length, breadth, and the thickness of the individual segments; the head is also somewhat larger, abruptly truncated at the crown, destitute of a proboscis and a hook-apparatus—hence this species has been described as the *hookless tapeworm*—but furnished with very large sucking-disks, sur

rounded by much dark pigment, which gives the head a blackish appearance. The specific name of *mediocanellata* has reference to an interesting and almost specific character in connection with the water-vascular system, into which we have not space to enter. Leuckart has proved by experiment that the measles or cysticerci which produced this worm are to be found in the muscles and internal organs of cattle. He administered proglottides of *T. mediocanellata* to three calves, a sheep, and a pig. In the two last-named animals they produced no effect, as was shown by their post-mortem examination; while in the calves they produced a kind of leprosy, which has since been characterized as "acute cestoid tuberculosis," and which proved fatal if too large a dose of eggs was administered. On examining one of these animals after its restoration to health—48 days after the eggs were swallowed—he found numerous cysticercus-vesicles, larger and more opalescent than those of the pig, lodged in the muscles; and as the heads of the contained cysticerci exhibited the distinctive peculiarities presented by the head of the adult worm, "we are supplied with the most unequivocal evidence that man becomes infested with this second form of tapeworm by eating imperfectly cooked veal and beef." Hitherto the two above-described species have commonly been included under *T. solium*, from want of due examination, especially of the head. Dr. Cobbold believes that their respective frequency will ultimately be found pretty well on a par, though probably the *T. solium* will maintain a slight ascendancy, in consequence of the relative cheapness of pork. "Admitting occasional exceptions," he observes, "the hooked worm infests the poor, and the hookless worm the rich. This circumstance accords with the fact, that the lower classes subsist chiefly upon pork, while the wealthier prefer mutton, veal, and roast beef."—*Entozoa*, p. 243. It gives rise to the same symptoms as the *T. solium*.

The next five tapeworms infesting man may be passed over without notice, as being of very rare occurrence. *Tenia acanthotrias* is only known from a single case, in which, in the larval stage, it was found in the muscles of a woman. The last species we shall describe, the *T. echinococcus*, is, in its larval condition, probably more fatally injurious to the human race than all the other species of entozoa put together. In its mature (strobila) condition, in which it is found only in the dog and wolf, it seldom exceeds the fourth of an inch in length, and develops only four segments, including that of the head. The final segment, when sexually mature, equals in length the three anterior ones, and contains as many as 5,000 eggs. The proscœlex or embryo forms large proliferous vesicles, in which the scolices or larvæ (known also as acephalocysts, echinococci, echinococcus heads or vesicles, pillbox hydatids, etc.) are developed by gemmation internally. The eggs develop in their interior a six-hooked embryo, and these embryos are introduced into our bodies with food or water into which the eggs have been carried. "With an especial liking for the liver," says Dr. Cobbold, "they bore their way into this organ, or are carried along the circulating current to other organs. In these situations they sooner or later become transformed into simple vesicular, bladder-like bodies, commonly called acephalocysts or hydatids." Instead, however, of displaying the head, neck, and body of a cysticercus, the vesicle retains a globular figure. Its growth is slow, and many months elapse before echinococci are developed within our bodies, after we have swallowed the proper tapeworm eggs and their contained embryos. There have been great differences of opinion among physiologists as to the mode of development of these echinococci; but the following is probably the current view: The inner surface of the vesicle presents after a time slight papillæ or prominences, which, as they enlarge and become oval, are eventually scoleciform, and contain a cavity filled with a limpid fluid. This scolex-like development produces in its interior a brood of scolices or echinococcus heads, or, in other words, becomes gradually transformed into the so-called "brood-capsules" of helminthologists. It is almost impossible to explain the nature of these brood-capsules, with young echinococci in their interior, without the aid of such diagrams and illustrations as are given by Cobbold in his chapter on *T. echinococcus*. In the fully developed state the echinococci vary from $\frac{1}{80}$ to $\frac{1}{100}$ of an inch in diameter. The rostellum supports a double curve of hooks, those in the smaller row varying in size from $\frac{1}{140}$ to $\frac{1}{175}$ of an inch, while those of the larger series are from $\frac{1}{80}$ to $\frac{1}{175}$ of an inch. Below the hooks are four suckers, and the general appearance of the body is finely granulated, from its containing calcareous particles. It often happens that the discovery under the microscope of a few of these little hooks at once decides the nature of an otherwise mysterious tumor. Of 373 cases of the parasite occurring in man, collected by Davaine (who devotes more than one-third of his *Traité des Entozoaires* to this subject, 165 affected the liver, 40 the lungs, 30 the kidneys, 20 the brain, and 17 the bones, while the remainder were spread over other parts; and of 136 cases collected by Cobbold, 51 affected the liver. No less than 35 of these 51 cases recovered. "Four of them were complete natural cases; two others being also temporarily cured in the same. All the rest were cured by surgical operations." It is impossible to state with accuracy the degree of prevalence of hydatids in this country, or the extent to which it proves fatal. In Iceland this disease is endemic to such a degree that about one-sixth of the population are affected with it. It produces a long illness, terminating with a painful death, and no means of cure have yet been discovered. Its prevalence in that island may be rationally accounted for. Firstly, every peasant has, on an average, six dogs, all of which are probably infested by the

mature tapeworm; and secondly, there being only six legally authorized medical men, the great majority of the population (over 10,000 persons, scattered over 1500 sq. m.) are in the hands of quacks, whose principal treatment consists in the administration of fresh dog-excrement. Our authority for this astounding specimen of homeopathic treatment is Leuckart, whose admirable popular essay, *On the Newest Discoveries regarding Human Intestinal Worms, and their Importance in Relation to Hygiene*, in the *Conversations Jahrbuch* (1863), is deserving of the most careful study. For an excellent abstract of the remarkable series of experiments—extending from 1851 to the present day—by which the relationship between the so-called cystic worms and the cestoid worms was established, we may refer the reader to Aitken's *Science and Practice of Medicine*, vol. i.; while for the subject of tapeworm generally, the highest authorities are the works of Küchenmeister and Siebold, translated by the Sydenham society; Davaine's *Traité des Entozoaires*; Weinland's *Essay on the Tapeworms of Man*; Lueckart's *Das Menschlichen Parasiten* (Leipzig, 1863-76); and Cobbold's *Entozoa* (1864), a work equally remarkable for the vast amount of original research which it contains, and for the beauty and correctness of the illustrations.

Tapeworms, although rare among horses and cattle, are common in dogs and sheep, causing irritability of the bowels, and an unthrifty appearance. For dogs no remedy answers so well as powdered areca nut, of which 30 grains suffice for a dog weighing about 20 lbs. It is best given after 10 or 12 hours' fasting, in a little soup or milk, and should be followed in a few hours by a dose of castor oil. Neither areca nor any of the approved remedies used in men, prove effectual in sheep; and one of the best prescriptions for them consists of 40 drops of oil of turpentine, a dram of powdered green vitriol, and an ounce of common salt, given mixed in a little milk or gruel, or, where their bowels are confined, in linseed oil. A daily allowance of linseed cake and sound dry food should likewise be given with the grass or roots, and pieces of rock-salt left within the animal's reach. See illus., WORMS, ETC., vol. XV.

TAPIO'CA. See MANIOC and CASSAVA.

TAPIR, *Tapirus*, a genus of *pachydermata*, of the section *ordinaria*; having a bulky form, with moderately long legs; the fore-feet four-toed, the hind-feet three-toed; the skin thick, the hair short; the tail very small; the neck thick; the ears short; the eyes small; the muzzle elongated; the nose prolonged into a short, flexible proboscis, which, however, does not terminate in an organ of touch and prehension, like that of the elephant; 6 incisors, 2 canine teeth, and 14 molars in each jaw, the molars separated from the canine teeth by a wide interval. The best known species is the AMERICAN TAPIR (*T. Americanus*), which is about the size of a small ass, and is common in almost all parts of South America, its range extending as far s. as the strait of Magellan, although it suddenly ceases to be found at the isthmus of Darien. Its color is a uniform deep-brown, but the young are beautifully marked with yellowish fawn-colored stripes and spots. The skin of the neck forms a thick rounded crest on the nape, with a short mane of stiff hair. The tapir inhabits deep recesses of the forest, and delights in plunging and swimming in water. It feeds chiefly on young shoots of trees, fruits, and other vegetable substances, but is ready to swallow almost anything that comes in its way. Pieces of wood, clay, and pebbles are often found in its stomach. It sometimes commits great ravages in cultivated grounds; a large herd of tapirs sallying forth from the forest by night, trampling and devouring all that they find in the fields. The tapir is a very powerful animal, and, protected by its thick hide, forces its way through the forest where almost no other quadruped can. When assailed by the jaguar it seeks to get rid of him by rushing through thick underwood, and if it can reach water is often successful by plunging in and diving. It is inoffensive, never attacking man; but when hard pressed by dogs makes a violent resistance, and inflicts severe bites. It is very easily tamed, and becomes extremely familiar; but its large size makes it a troublesome pet. Its hide is useful, and its flesh is eaten, although rather dry.—The MALAYAN TAPIR (*T. Malayanus* or *Indicus*) is found in Malacca, Sumatra, etc. It is larger than the American tapir, and its proboscis is rather longer in proportion. The neck has no mane. The color is glossy black, except the back, rump, and sides of the belly, which are white. The colors do not pass gradually one into another, but the line of separation is marked, giving the animal a very peculiar appearance. The habits of this species are very similar to those of the American tapir, and it is equally capable of domestication. The young are striped and spotted as in that species.—A third species is found in the mountainous parts of South America.

The remains of tapirs have been found in miocene and subsequent strata. In all about 12 species have been determined. Tapir-like animals are common in eocene beds. Ten species of *paleotherium* (q. v.) have been described. *Lophiodon*, of which 15 species have been observed, differs from *paleotherium* in the structure of the teeth of the lower jaw—and from other peculiarities in the same organs, *coryphodon* (containing three species) has been separated from both genera.

The tapir is a remarkable exception to the generalization deduced from the comparison of the later tertiary mammals with those living in the same districts at the present day, viz., that there is a close correspondence between the fauna of the two periods. The pliocene and post-pliocene bears, hyenas, tigers, elephants, etc., of Europe and Asia

are represented by living species of the same or nearly allied genera. The recent sloths, armadillos, and prehensile-tailed monkeys of South America were preceded by closely related forms in the later tertiary period; as were also the marsupials of Australia. Several species of tapirs have been found in Europe, but they have left no representatives nearer than eastern Asia and South America. See illus., MAMMALIA, vol. IX.

TAPPAN, ARTHUR, 1786-1865; b. Mass.; received a common school education; was clerk in a hardware store in Boston, 1800-7; removed to Montreal, Canada, but after the breaking out of the war (1812) he established himself in New York in the dry-goods importing business in 1814, where he was greatly prospered. He was one of the founders of the American tract society, and gave liberally for its first building; aided in establishing and endowing Lane Theological Seminary (Presbyterian), Cincinnati; founded a professorship in Auburn Seminary; erected Tappan Hall, Oberlin; established with his brother Lewis the *Journal of Commerce*, New York, 1828. A vigorous opponent of slavery, he established at his own expense the *Emancipator*, 1833; originated the New York city anti-slavery society; was appointed president of the American anti-slavery society formed in Philadelphia, contributing to it for some time \$1,000 per month; failed in 1842 and went into bankruptcy, giving up all his personal property. He was afterward connected with the "mercantile agency" established by his brother. He left a high reputation for integrity, earnestness, and benevolence.

TAPPAN, BENJAMIN, 1773-1857, b. Mass.; brother of Arthur and Lewis; at first a copper-plate engraver and printer. After giving considerable attention to portrait-painting he studied law, and was admitted to the bar. In 1803 he was a member of the legislature of Ohio, whither he had removed in 1799. He served in the war of 1812 as an aid-de-camp to Gen. Wadsworth. He was afterward for several years presiding judge of the 5th Ohio circuit. In 1833 he became U. S. district judge for Ohio. He was U. S. senator, 1839-45. He was connected with the democratic party till 1848, when he became a free-soiler. He published in 1831 a volume of *Reports* of cases in the court of common pleas.

TAPPAN, DAVID, D.D., 1752-1803; b. Mass.; graduated at Harvard college, 1771; studied theology two years; became pastor of the Third Church (Congregational), Newbury, Mass.; Hollis professor of divinity in Harvard college, 1792, in which position he remained till his death. He published about 30 sermons and addresses, and after his death appeared *Sermons on Important Subjects*; *Lectures on Jewish Antiquities*.

TAPPAN, HENRY PHILIP, D.D., b. N. Y., 1805; graduated at Union college, 1825; studied theology two years at Auburn seminary; assistant pastor of the Reformed church, Schenectady, N. Y.; pastor of a Congregational church, Pittsfield, Mass., 1823-31; professor of mental and moral philosophy in the university of New York, 1832-38; taught a private school for several years in New York; chancellor of the Michigan university, 1852-63; elected corresponding member of the French Imperial Institution, and president of the American Association for the Advancement of Education. He published *A Step from the New World to the Old*, the results of his inquiry into the working of university education in England and Prussia; *Review of Edward's Inquiry into the Freedom of the Will*; *The Doctrine of Will Determined by an Appeal to Consciousness*; *The Doctrine of the Will Applied to Moral Agency and Responsibility*; *Elements of Logic*; *Illustrations of Personages of the Nineteenth Century*; *Treatise on University Education*. His three works on the will were republished in Glasgow. He d. 1881.

TAPPAN, LEWIS, 1788-1873; brother of Arthur and Benjamin; b. Mass.; was a merchant and cotton manufacturer in Boston; removed to New York in 1827; joined his brother Arthur in establishing the *Journal of Commerce*, of which he was sole proprietor, 1828-31. He took a decided stand against slavery, and for his abolition sentiments and efforts his house was sacked by a mob in 1834; failed in the financial disaster of 1837; established a "mercantile agency." He was active in anti-slavery and benevolent associations; was treasurer and president of the American Missionary Association, founded mainly through his efforts, and one of the early members of Plymouth Church, Brooklyn. He published a *Life of Arthur Tappan*.

TAPPAN BAY, or TAPPAN SEA, reaches from a point about 24 m. n. of New York for a distance of 12 m., being an enlargement of the Hudson river. Its greatest width is 4 m., and it lies between Rockland and Westchester counties, N. Y.

TAPPING is an operation which is most commonly performed on the abdomen, but occasionally on the chest and head. Tapping of the abdomen gives great relief when the abdomen becomes inconveniently distended with fluid contained in the peritoneal sac, or, in the case of the female, in an ovarian cyst. A small incision is then made about 2 in. below the navel, through which the cutting surfaces of the trochar—the instrument used in this operation—are passed. By arrangements, into which we need not enter, the fluid escapes through this instrument. The wound made by the trochar in the abdomen will, in ordinary cases, heal in a few days.

Tapping of the chest is an operation which is occasionally required for the relief of empyema and other effusions in the cavity of the pleura. Tapping of the head has been occasionally found successful in hydrocephalus. Tapping of the pericardium has been

practiced in cases of pericardial dropsy, but it is an operation not to be recommended under any circumstances.

TAPTI, a river of the British presidency of Bombay, India, rises in the Saugur and Nerbuddah territories, in lat. about $21^{\circ} 46'$ n., flows w. through Scindhia's dominions and the districts of Candesh and Surat to its mouth in the gulf of Cambay, 17 m. below the town of Surat. It is 457 m. in length; but can hardly be said to be navigable, for even small vessels of from 40 to 50 tons burden cannot ascend higher than Surat.

TAR is a complex, strong-smelling, dark-colored substance of oily consistency obtained in the destructive distillation of peat, wood, coal, bones, and other organic substances. Its composition varies, depending upon its source and the conditions of its manufacture. Wood-tar is often the chief object of the process that yields it, but the other tars are by-products, obtained in industries carried on primarily for other purposes. Peat-tar is produced in the manufacture of illuminating gas or charcoal from peat; coal-tar comes from the gas or coke furnaces; while bone-tar has its source in the bone-black industry. The tar from bones is especially rich in compounds containing nitrogen, while wood-tar contains least of the ammonia and other nitrogenous constituents, but most, in comparison with other tars, of oxidized products like acetic acid and wood alcohol.

BONE-TAR, the least in commercial importance, is a rank-smelling liquid known as Dippel's oil, used chiefly for lubricating purposes. A number of pure substances have been isolated from it, among them the pyridin bases—pyridin (C_5H_5N), picolin (C_6H_7N), lutidin (C_7H_9N).

WOOD-TAR, when made as a by-product in the manufacture of gas from wood, is collected much like coal-tar. But it is commonly made from the resinous roots and wood of various pines in Scotland, in the north of Europe, and largely in South Carolina and Georgia. The wood is heaped into a conical stack upon a surface depressed at the centre, covered with earth and fired. The tar runs to the centre, from which a drain pipe conveys it to receptacles outside. This process causes the waste of the illuminating gases, much of the wood-naphtha and pyroligneous (or acetic) acid; so that the process is economically conducted in retorts with reference to saving all the products, the illuminating gas being used as fuel to heat the retorts. This tar is largely used for water-proofing, preservative, and antiseptic purposes, and for the manufacture of some black pigments. Among the compounds which have been separated from it are the solids, paraffine ($C_{25}H_{52}$), naphthalene ($C_{10}H_8$), cedricet ($C_{16}H_{16}O_6$), pyrene ($C_{16}H_{10}$), chrysene ($C_{18}H_{12}$); and the liquids, toluene (C_7H_8), xylene (C_8H_{10}), cymene ($C_{10}H_{14}$), creosote, a mixture, acetic acid ($C_2H_4O_2$), and wood naphtha (CH_4O). Wood-tar, under the name of *Pix liquida*, has place in the Pharmacopœias, U. S. and Br., and in doses of one or two grains is looked on with perhaps increasing favor as a remedy in diseases of the mucous membrane of the respiratory passages. Bishop Berkeley's commendatory essay on the use of tar-water in diseases of the chest and kidneys is often quoted (see Chambers' *Book of Days*, vol. i., p. 108).

COAL-TAR has come into great commercial importance within a few years, and an indefinite number of useful compounds are made from it. The products of distillation of coal may be briefly divided into four groups—the volatile products used after purification for illumination; the products dissolved by water, consisting chiefly of compounds of ammonia; the insoluble products condensed in water constituting the *tar*, and the coke and gas carbon remaining in the retorts. The vapors from the hot retorts are led directly into a large pipe carrying water—the hydraulic main—and here the tar condenses to a liquid and is conducted to a reservoir. It is afterwards subjected to distillation in iron retorts, with gradually increasing heat, and separated into fractions of different boiling points. It is out of the question in small space to give all the fractions, or even allude to the different methods employed; but the following, partly from Roscoe, will give a general idea of the processes and products:

The *first burnings* amount to about 2 to 4 per cent. of the tar and contain carbon disulphide, paraffines, benzine, etc., and some ammonia water. The receiver is changed at 110° C. The next product is the *light oil* or *crude naphtha* containing benzine (C_6H_6), toluene (C_7H_8), xylene (C_8H_{10}) and similar compounds of higher boiling point, and constituting 7 to 8 per cent. of the tar. The light oil floats on water and comes over between 110° and 210° C., though in some works a middle oil is taken between 170° and 230° C. From 210° to 400° C. comes the *heavy* or *dead oil* (which sinks in water), some 25 per cent. of the tar. The dead oil contains carbolic acid (phenol, C_6H_5O), naphthaline ($C_{10}H_8$), anthracene ($C_{14}H_{10}$), anilin (C_6H_7N). And there is left in the retort a black substance, becoming brittle on cooling—the *pitch*.

These various fractions are further split by subsequent distillation with reference to commercial demands. The light oil is distilled to secure in the distillate all the benzine; the product, which contains much of the toluene also, is used in the manufacture of anilin dyes. The dead oil may be separated into *carbolic oil*, *creosote oil*, and *anthracene oil*. The carbolic oil is used for the manufacture of carbolic acid and naphthaline, the latter being a solid used in the manufacture of dyes. The creosote oil is used also for naphthaline, or, entire, for preservative purposes. From the anthracene oil is obtained the valuable solid anthracene used in the manufacture of alizarin dyes. The pitch is

used for pavements, acid-proof varnishes, and lamp-black. In order to soften it, it is melted with the residues from the carbolic and creosote oils. These are but a few of the constantly increasing uses of the coal-tar products. Within a few years many medicines and antiseptics have been prepared from it, such as saccharin, acetanilid, antipyrin, pyrrrol, cresol. Its greatest application, however, is in the manufacture of a great variety of brilliant dyes.

TARA, or **TARO**, *Colocasia macrorrhiza*, a plant of the natural order *aracea*, of the same genus with the coco (q.v.), or eddoes, and cultivated for its roots, which are a principal article of food in the South Sea Islands. The roots are 12 to 16 in. long, and as much in girth. They are washed to take away their acidity, which is such as to cause excoriation of the mouth and palate. They are cooked in the same way as bread-fruit, the rind being first scraped off. A pleasant flour is made of tara.

TARA FERN, *Pteris esculenta*, a species of brake (q.v.), the root (rhizome) of which was one of the principal articles of food of the New Zealanders, before the settlement of New Zealand by British colonists. This fern comes to perfection only in good soils, and there the plant is ten ft. high. Plants three years old furnish the best roots, which are about an inch in circumference. The root, being dug up, is cut in pieces about 9 in. long, and placed in stacks, carefully protected from rain.

TARANTELLA, an Italian dance, deriving its name from Taranto. It is written in 6-8 time, constantly increasing in speed, and alternating in the major and minor. The dancing of the Tarantella was thought to be a remedy for curing a strange kind of insanity, the effects of the bite of the *Lycosa tarantula*, the largest of European spiders. A disease called Tarantism prevailed in Italy during the 15th, 16th, and 17th centuries, but it is not certain that it was caused by the bite of the spider. Bands of musicians traveled throughout the country to play the music, which was the only effective medicine. Few of the songs used to cure Tarantism exist. Jones's *Maltese Melodies* (London, 1805); Stafford Smith's *Musica Antiqua* (1812), and Mendel's *Lexicon* contain a few specimens. Many modern composers have written Tarantellas which bear little resemblance in rhythm and style to the early melodies. Among the most noted are by Thalberg and Heller, for the pianoforte, and a vocal Tarantella, *La Danza*, by Rossini. Auber has introduced it into *La Muette di Portici*, and Mendelssohn in his *Italian Symphony*. See N. Perotto, *Cornocopia* (Venice, 1480); A. Kircher, *Magnes* (Rome, 1641); Hermann Grube, *De Ictu Tarantulae* (Frankfort, 1679); Serao, *Della Tarantella* (Rome, 1742); Vergari, *Tarantismo* (Naples, 1839); and Engel, *Musical Myths* (London, 1879).

TARANTISM may be defined a leaping or dancing mania, originating in, or supposed to originate in, an animal poison. The name is supposed to be derived from the ground-spider, *tarantula* (q.v.), which conveyed the poison into the human body by its bite. The gesticulations, contortions, and cries somewhat resemble those observed in St. Vitus's dance, and other epidemic nervous diseases of the middle ages, with which tarantism was contemporaneous; but the affection differed from these in its origin, in the cachexia present, in the elegance of the movements of the victims, in their partiality for red colors, bright and luminous surfaces, their passion for music, and in their restoration depending upon the use of instrumental or vocal music as a remedy. Although the sufferers were subjected to extraordinary treatment, such as being buried up to the neck in earth, the success of music was so universal and invariable, that a class of tunes, it is said, was composed, called *tarentella*, to be employed in the cure of the tarantati. These have lingered long after the extinction of the malady, and may still be heard in the wilder districts of Italy. While it is highly probable that the physical symptoms were due to the bite of spiders, the mental disturbances and muscular *agitation* should be traced to the secondary effects of these upon the nervous system and imagination. It appeared in various parts of Italy, but was most prevalent in Apulia, where the insects abound. No age or class appears to have been exempt, for we read of a philosophic bishop who allowed himself to be bitten by a tarantula, dancing, etc., as fast and furiously as the peasantry.

TARANTO (anc. *Tarentum*), a town of s. Italy, in the province of Lecce, is situated on a rocky islet, formerly an isthmus, between the Mare Piccolo (Little Sea), an extensive harbor on the e. or landward side of the town, and the Mare Grande (Great Sea), or gulf of Taranto, on the west. The harbor is one of the finest in the country, the entrance being between Cape San Vito and the island of San Pietro. The largest vessels can enter safely. The principal buildings are a cathedral, dedicated to St. Cataldo, a native of Raphoe in Ireland, who was first bishop of Taranto; a fine episcopal palace; a castle and fortifications, erected by Charles V., and commanding both seas; and two hospitals. The streets are as narrow and dark as those of an oriental city. Taranto has manufactures of velvets, linens, and cottons, but little commerce. The Mare Piccolo, however, is still famous (as of yore) for its immense abundance of shell-fish, and a considerable portion of the population derives its subsistence from the oyster and mussel fisheries. Pop. '81, 33,942; according to later estimates about 40,000.

Ancient Tarentum, however, was a far more famous and splendid city than its modern representative. Founded by a body of Spartan emigrants about 708 B.C., it grew and prospered for centuries in happy obscurity. Its territory was not perhaps very fertile, but its pasturage was of the finest, and its olive groves were unsurpassed. Yet it

was not these things that ultimately made it the sovereign city of Magna Græcia; this rank it attained through the supreme excellence of its harbor (the Mare Piccolo), ample and secure beyond all the other harbors of lower Italy. Gradually it became the chief emporium of the Græco-Italian trade, and long after all the rest of the colonial cities in Magna Græcia had fallen into decay, Tarentum was "blooming alone" in undiminished prosperity. We may pass over its earlier history, noticing only the fact, that in the 4th c. B.C., it had for its *strategos*, or general (seven times), the philosopher and geometer Archytas, under whom it became the headquarters of the Pythagorean sect, and was honored with a visit from Plato, who was the guest of Archytas during his residence there. But while in the very acmé of its greatness, it provoked a quarrel with Rome (q.v.), 281 B.C., in which, though aided by the gallantry of Pyrrhus (q.v.), king of Epirus, it was utterly crushed, after a struggle of less than ten years; and though its natural advantages hindered it from sinking into such absolute insignificance as other cities of Magna Græcia, it was never after a place of great importance. Under the empire it was quite overshadowed by Brundisium on the Adriatic, but rose again during the Gothic wars, and passed into the hands of the Saracens and Greeks, from the latter of whom it was wrested by Robert Guiscard, the Norman, in 1063. Since then, it has shared the fortunes of the kingdom of Naples. Few relics of the classic Tarentum are extant, the chief being bits of an amphitheater, a circus, and traces of some of the temples.

TARAN'TULA, *Lycosa tarantula*, a species of spider, of a genus to which the name wolf-spider is often given, a native of the s. of Europe. It derives its name from the city of Taranto, in Italy, where it is very plentiful. It is one of the largest of European spiders, of a somewhat elongated shape, with rather long legs. It is one of those spiders which seek their prey by hunting. Its bite is much dreaded, and has been supposed to cause the disease called *tarantism* (q.v.).—Several species of spider nearly allied to the tarantula are found in different parts of the s. of Europe. One of them (*lycosa narbonensis*) frequents dry uncultivated grounds in the s. of France, and makes a little pit in the ground, near the entrance of which it sits watching for prey. The prey is carried into the pit to be devoured. A spider called tarantula is common in Texas.

TARARE, a thriving and important manufacturing t. of France, in the dep. of Rhône, stands at the foot of mount Tarare, one of the highest summits of the Beaujolais range, 22 m. n.w. of Lyons. Formerly unimportant, it is now a rich and flourishing town, the inhabitants of which are engaged in the manufacture of muslins, cloth, silk, and merino fabrics, and in embroidering and bleaching. The muslins of Tarare are famous for their fineness. See TARLATAN. Pop. '91, 11,783.

TARASCON, a t. of France, in the dep. of Bouches-du-Rhône, 8 m. n. of Arles. The church of St. Martha dates from the year 1187, and is so called after Martha, the sister of Lazarus, and the patron saint of the town. Woolen and silk fabrics, and brandy and vinegar, are manufactured. The town acquired considerable note, and of a sort that was displeasing to its inhabitants, it is said, by Daudet's well-known *Tartarin de Tarascon*. Pop. '91, 6597.

TARAX'ACUM, or dandelion (q.v.) root, is employed to a considerable extent in medicine. The roots should be gathered in August and September, when the juice is most abundant. There is no very satisfactory analysis of this juice, but it is said to contain mannite, resin, sugar, gum, caoutchouc, and a crystallizable matter termed *taraxicine*, on which its active properties probably depend. This medicine may be prescribed with advantage in the form of extract, decoction, or juice in chronic diseases of the liver, and in certain forms of dyspepsia and skin-disease which are accompanied by derangement of the biliary organs. In very large doses, it has a diuretic and slightly aperient action.

TARAZO'NA, a t. of Spain, in the province of Saragossa, 43 m. n.w. of the city of that name, on the Queyles, a tributary of the Ebro. It stands on a wind-blown plain, exposed to bleak winds from the Sierra de Moncayo on the s., and from the Pyrenees on the north. It contains a cathedral with a slender brick spire and rich interior, a bishop's palace, and a Moorish *Alcazar*. Pop. '87, 8538, mainly engaged in agriculture.

Tarazona is the ancient *Turiaso*; and here a few Roman troops routed a Celtiberian army. It became a municipium under the Romans; and under the Goths, by whom it was fostered, it became famous for its steel.

TARBAGATAI', a military frontier district of Chinese Turkestan; also the name of a range of mountains forming the boundary line between this district and the Russian province of Semipolatsk. Area of the district, about 25,500 sq.m.; pop. about 64,000. The population is largely nomadic. The mountains reach a height of about 10,000 ft.

TARBES, a t. in the s. of France, capital of the dep. of Hautes-Pyrénées, stands on the left bank of the Adour, 23 m. e.s.e. of Pau. It is a station on the *Chemin de fer du Midi*, and the center of communication with all parts of the Pyrenees, the lofty line of which bounds the prospect on the south. The modern cathedral and the museum are the principal and indeed the only notable buildings. The manufactures include paper, flax, woollens, and machinery. Tarbes is the seat of an active general trade. Pop. '95, 25,087.

Tarbes dates from the time of the Romans, and its bishopric was founded in the year 420.

TARDIGRADA. See SLOTH.

TARE, *Ervum*, a genus of plants of the natural order *leguminosæ*, sub-order *papilionaceæ*, distinguished from *vicia* (see VETCH), to which it is nearly allied, by a capitate stigma, downy all over. It contains only a few species of weak climbing plants, natives of the temperate parts of the Eastern Hemisphere. One of these is the LENTIL (q.v.).—Two (*E. hirsutum* and *E. tetraspermum*), generally known by the name of TARE, are common in cornfields and hedges in Britain. They have very small flowers and pods; the leaves are pinnate, and the leaflets small. They afford nourishing food for cattle, but the quantity is so small that they are not worthy of cultivation, and are chiefly known as a nuisance in cornfields. A species of tare (*E. sativum*), with an upright branching habit, is cultivated in some parts of Europe for its herbage, which is used for feeding cattle. The bulk of herbage is small, but its nutritious character is thought to compensate for this. The leaves have from 8 to 14 pair of leaflets. The plant thrives well in poor sandy soils.—It is not supposed that the tare of the New Testament has any affinity to these plants: it is doubtful what it is, but it appears not improbable that it is the DARNEL (q.v.).

TARE AND TRET, certain deductions usually made from the gross weight of goods. *Tare* is the weight of the box, cask, bag, or wrapping in which the goods are contained; and the amount is obtained either by weighing the empty package itself, by taking an average of a few similar packages of equal size, or by mutually agreeing upon a certain proportion of the gross weight. The remainder, after deducting the tare, is the *net weight*. Another deduction, at the rate of 4 lbs. for every 104 lbs., or $\frac{1}{26}$ of the net weight, is then made, as an allowance for waste through dust, etc., and is called *tret*. Some other allowances of minute magnitude as draft, cloff, etc., are occasionally made after tret, but they are falling into disuse.

TARGET (root uncertain, but the word, in some form, found in all European languages), in its modern sense, is the mark for aiming at in practicing with the cannon, rifle, or bow and arrow. In its more ancient meaning, a target or targe was a shield, circular in form, cut out of ox-hide, mounted on light but strong wood, and strengthened by bosses, spikes, etc. Of modern targets, the simplest is that used for archery (q.v.). With regard to rifle targets, the spread of the volunteer movement and the numerous rifle-matches have caused ranges to be constructed over the whole country. The necessities are: a butt, artificially constructed or cut in the face of a hill, to prevent wide balls from scattering—a marker's shot-proof cell, near the targets—and a range of such length as can be procured. The sizes of targets used by the British army are as follows: for firing up to 300 yards, the target is 6 ft. high by 4 ft. broad, with a circular bull's eye 1 foot in diameter, and a center of 3 feet. Up to 600 yards, the target is 6 ft. square; bull's eye, 2 ft. diameter; center, 4 feet. Up to 800 yards, the target is 6 ft. by 8; bull's eye, 3 ft. in diameter; and center, 5 feet. The marker signals the "hits" from his box, denoting a bull's-eye by a red-and-white flag, a center by a blue flag, and an outer by a white flag. If he show a red flag, it is to cease firing while he inspects the target. In scoring, the outer counts 2; center, 3; and bull's-eye, 4. A red flag should fly on the butt during the whole time of practice, to warn passers-by to keep off the range. The targets used by the National Rifle Association at Wimbledon are not the same as those used by the army. According to the Wimbledon regulations of 1876, the target for the distance of 200 yards had a circle of 40 in. diameter, divided into the circular bull's-eye 8 in. in diameter, a center of 16 in. diameter, an "inner" of 28 in., the rest of the 40 in. being accounted "outer." On the target for 500 and 600 yards, the circle of 70 in. falls into a bull's-eye of 22 in. diameter, center 38 in., inner 54 in., and the rest outer. The rectangular frame for 800, 900, and 1000 yards distance had a circular bull's-eye of 3 ft. in diameter, a center 4 ft. 6 in., a square inner of 6 ft., the remainder of the target counting as outer. Of the ordinary Wimbledon targets for successive years, that for 200 yards distance is divided into a bull's-eye 8 in. in diameter; "inner," 1 foot; "magpie," 2 ft.; and outer, the remainder of the target 4 ft. square. At 500 and 600 yards, the bull's-eye is 2 ft. in diameter; the inner, 3 ft.; the magpie, 4 ft.; and outer, the rest of the target of 6 ft. square. At 800, 900, and 1000 yards, the bull's-eye is 3 ft. diameter; inner, 4½ ft.; magpie, 6 ft. square; and outer, the rest of the target of 12 ft. by 6 feet.

Previous to the inaugurating of the Wimbledon meeting in 1860, all targets were circular, and made of iron. From that year till 1873 inclusive, they were square iron plates; but in 1874 targets of canvas stretched on an iron frame were introduced.

TARGOWITZ, or TARGOWICZA, in Russia, a small t. in the government of Kief (q.v.), on the borders of Kherson, was the scene (May, 1792) of a confederation ("plot" as the patriots had it) of the five Polish nobles (Potocki, Branecki, Bzeureski, and two others of little note) who were adverse to the constitution of May 3, 1791. They were incited to this traitorous conduct toward their country by Catharine II., and after their conduct had been fully unveiled, they were declared traitors to their country, and only escaped death by precipitate flight to Russia, where they were munificently rewarded for

the treason which had given the czarina a pretext for executing the second partition of Poland (q.v.).

TARGUM (Chaldee, from *tirgem*, a word of uncertain origin, designating to translate, explain), the general term for the Aramaic versions of the Old Testament, which became necessary when, after and perhaps during the Babylonian exile, Hebrew began to die out as the popular language, and was supplanted by "Chaldee," an idiom, or rather a family of idioms, on which we have spoken under **SHEMITIC LANGUAGES**.

The origin of the Targum itself is shrouded in mystery. The first signs of it—as an already fixed institution—have been found by some in the book of Nehemiah, and according to tradition, Ezra and his coadjutors were its original founders. However this be, there can be no doubt that its beginnings belong to a comparatively early period. The Mishna (q.v.) contains a number of strict injunctions respecting it, and also respecting a certain guild of meturgemans (whence dragoman) or interpreters, who had sprung up as professional followers of those learned men who, at a previous period, had volunteered their services in the translation and paraphrastic interpretation, both activities, as we said, implied by the term. At first, and indeed for many centuries, the Targum was not committed to writing, for the same reason that the "oral law" itself was not at first intended ever to become fixed as a code for all times. In the course of time, however, both had to yield to circumstances, and their being written down was considered preferable to their being utterly forgotten, of which there was no small danger. Yet a small portion only of the immense mass of oral targums that must have been produced, has survived. All that is now extant are three distinct targums on the Pentateuch, a targum on the prophets, targums on the Hagiographa, viz., on Psalms, Job, Proverbs, the five "Megilloth" (Song of Songs, Ruth, Lamentations, Esther, Ecclesiastes), two targums on Esther, one on Chronicles, one on Daniel, and one on the apocryphal pieces of Esther. The most important of the three Pentateuch targums is the one named after Onkelos (q.v.), probably a corruption of Akylas, whose Greek version had become so popular that this Chaldee version was honored with being called after it. In its present shape, this translation dates probably from the end of the 3d or beginning of the 4th c. A.D., although snatches of it were collected and written down more than a hundred years earlier. We have spoken of its language and its general character already under **ONKELOS**, and may here briefly state that it is composed in an Aramaic closely resembling that of Daniel, and that it is as excellent a translation "for the people," which it meant to be, as can well be conceived. Occasionally, when the subject imperatively demands it, it introduces some paraphrastic by-work, and it only deviates from the text where the divine dignity would have appeared to suffer in the eyes of the multitude by a literal interpretation. Its value for exegetical purposes is no less great than it would be for linguistic and antiquarian purposes, were it more explored with that view than has been the case as yet.

The two other Targums on the Pentateuch, hitherto known as Targum Jonathan ben Uzziel, and Targum Jerushalmi, are merely recensions of one and the same version—the name of the first recension being merely a perpetuated error of a single scribe—which owes its origin to Palestine or Syria (Onkelos being of Babylonian origin), and cannot well have been redacted before the 7th c. A.D. There is no doubt that originally this "Jerusalem Targum" embraced the whole of the Old Testament, as did the Babylonian; but nothing has survived beyond these two recensions of the Pentateuch, the first complete, the second in a fragmentary condition: the former probably intended as an emendation of Onkelos, chiefly in the direction of homiletic paraphrase and legendary lore, and the latter as a further emended emendation of single portions. As a version, this Targum is of small importance; but it is invaluable as a storehouse of allegories, parables, sagas, and the like popular poetry of its time. Its language and grammar are exceedingly corrupt; it abounds, moreover, with foreign—Greek, Latin, Persian, and Arabic—terms; and its general use lies more in the direction of Jewish literature itself, as well as of archaeology and antiquities of the early Christian centuries, than in that of a direct interpretation of the Bible text itself. The Targum on the prophets is generally and erroneously ascribed to Jonathan ben Uzziel, an eminent master of the law at the time of Hillel the elder; the fact being that, except one spurious Talmudical passage, in which mention is made of his having translated the Prophets, this Targum is everywhere else, from the Talmud down to the authorities of the 10th c. A.D., ascribed to one R. Joseph, president of a Babylonian academy in the 4th century. And it would indeed seem as if this statement was completely in accordance with the real facts—if not the writing, but the collection and final redaction of this Targum is ascribed to him. Respecting the nature of this version, it may be said that, while being tolerably literal in the first—historical—books, it gradually becomes a mere frame-work of Midrash (q.v.) or Haggada, which it introduces at every turn and at great lengths. It further contains historical bits, disguised, or rather typified, and some lyrical pieces of rare poetical value. In language and general manner, it resembles Onkelos, with which it is of one growth, place, and date, and of which it forms only a kind of continuation.

To the same Joseph "the Blind" to whom the redaction of the foregoing Targum is probably due, is further ascribed a Targum on the Hagiographa. But between him

and the Hagiographical Targums lie, at the least, 600 years; their date being approximately given as about 1000 A.D. Certain distinctions between the different books must further be made. The Targums on Psalms, Job, and Proverbs were probably contemporaneous compositions due to Syria. The two former are made more paraphrastic than the last, which resembles closely the Syriac version. The paraphrase on the five "Megilloth"—a very late production indeed—is principally a collection of more or less poetical fancies, traditions, and legends, to which the single verse in hand merely seems to furnish the key-note. There is, we need not add, but very little to be found in them of what originally must have formed the Targum on these books; nor is there the slightest hint to be found as to who was the real author or editor of their present form. That it was one man's work, is probable enough, from a certain unity of design and style noticeable in all of them. Their dialect lies somewhat between the e. and w. Aramaic. The Targum on the book of Chronicles—almost unknown until the 17th c.—also belongs to a late period, and was probably composed in Palestine. There are some useful philological, historical, and chiefly geographical hints to be gleaned from it, but nothing more; least of all can it be used exegetically. A Persian version of a Targum on Daniel (unedited) is all that has been discovered on that book as yet. It was probably composed in the 12th c., the influence of the early Crusades being plainly visible in it. On the paraphrase of the apocryphal pieces of Esther, we shall not dwell here, any more than on the scanty fragments of a "Palestinian Targum" that are found either interspersed in the general (Babylonian) Targum, or as independent pieces. It seems probable that more of this Palestinian version will come to light some day, as authorities of a few centuries back still quote from it rather largely. At present, however, their quotations are nearly all that remains.

Very little—we might say, next to nothing—has been done as yet to utilize this most important branch of Aramaic literature; in fact, not even an attempt at anything like a critical edition has been made, although it would be difficult to find a more corrupt text than that offered by the MSS. and single printed portions. Some parts have been done into Latin, English, German, etc. The ed. pr. of Onkelos is dated Bologna, 1482; that of the Targum on the Prophets, Leiria, 1494.

TARIFA, a seaport t. of Spain, in the province of Cadiz. It is the most southern town of Europe, is surrounded by tower-embattled walls, and communicates by a causeway with a small island, on which stand a fortress and light-house. The town is the most thoroughly Moorish in Andalusia; it is quadrangular in shape, and its streets are narrow and dark. Tunny and anchovy fisheries are actively carried on. Pop. '87, 13,206.

Tarifa, the Carthaginian *Josa*, and the Roman *Julia Traducta*, received its present name from the Moors, who are said to have called it after Tarif (=Tarik?) ibn Malik, who landed there to reconnoiter previous to the conquest of the country. See MUZA; RODERIC. It was successfully defended in 1812 by 2,500 troops (mostly British) against a French force of 10,000 men, under Victor and Laval.

TARIFF, in the United States, is a word oftenest used to denote the schedule of duties or imposts levied by act of Congress upon goods brought into the country from abroad. The traditional explanation of the origin of the word is that which identifies it with the name of the town Tarifa in Spain, which was itself called after the Berber chief Tarif ibn Malik. Here while the Moors held Spain, all vessels passing through the Straits of Gibraltar, at the narrowest part of which the town was situated, were compelled to stop and pay such duties as were imposed by the lords of the place. Hence the term *tariff* passed into the languages of different European peoples.

A tariff may be levied upon foreign goods for any one of three purposes: (1) simply as a means of augmenting the revenues of a government, in which case it is only one of the various forms of taxation (see TAX); or, (2) as a means of retaliating upon foreign governments for similar restrictions imposed by them, in which case it becomes, as M. de Laveleye says, an instrument of warfare serving a temporary purpose and designed in the end to secure commercial reciprocity (q.v.); or, (3) as a means of fostering artificially, particular industries by protecting them wholly or in part against foreign competition. These three forms of tariff and tariff-legislation will be discussed in detail in a subsequent portion of this article.

GENERAL HISTORY OF TARIFF LEGISLATION. A tariff for the purpose of revenue seems to have been usual among many of the civilized nations of antiquity. In the regal period of Jewish history transit duties were imposed upon foreign goods; and a tax upon foreign merchandise was one of the numerous sources of income that the public treasury possessed. Among the Greeks, especially the Athenian Greeks, a tariff was regularly resorted to as a means of revenue. This tariff was laid upon both exports and imports, and an additional tax was collected from vessels engaged in foreign traffic, for the use of the harbors in which they anchored. The regular export and import duty at Athens was two per cent., though in time of war, when the state was in pressing need of large sums of money, this tax was often considerably augmented. Thus, during the Peloponnesian War, a duty of five per cent. was collected upon all the imports and exports of the states subject to Athens; while Alcibiades collected a tariff of ten per cent. from the vessels that passed in and out of the Euxine Sea, a fortified custom-house being established at Chrysopolis (B.C. 410). This tax was known as *dekate*, and the custom-house *dekateutèrion*.

Import and export duties were also regularly levied by the Roman state, and for the same general purpose as that which led to their imposition in Greece. The name for this tax used by the Latin writers is *portorium*, a name applied likewise to transit duties and bridge tolls. The Roman *portorium* dates back to very early times, for we read in Livy (II.9) that Valerius Publicola exempted the plebeians from the tax at the time when Rome was threatened with an invasion by Porsena, which must have been earlier than B.C. 500. Velleius Paterculus says that Caius Gracchus greatly increased the list of dutiable articles, as did also the censors, M. Æmilius Lepidus and M. Fulvius Nobilior. In the provinces as well as in newly conquered countries, duties were likewise collected by Roman officials known as *portitores* and *publicani*, and the sums were transmitted to the Roman treasury. In some cases, however, the central government, as a particular favor, allowed the subject state to make its own customs laws, stipulating only that Roman citizens should be exempted from paying them. In B.C. 60 all *portoria* were abolished by the Lex Cæcilia so far as concerned the ports of Italy; but Julius Cæsar soon after restored them. Augustus Cæsar still further increased the number of dutiable commodities, and a long list of those that under the later emperors were subject to the payment of a duty is given in the Digest of Justinian. The custom-house officers had the right to search the persons of those arriving from abroad, and smuggling appears to have flourished in ancient as in modern times. Goods "declared" by the traveler to the custom-house officers were known as *scripta*, and those not so declared were styled *in-scripta*. The latter, if found, were liable to confiscation. The rate of duty at Rome seems generally to have been five per cent., but under the later emperors the very large duty of 12½ per cent. (*octava*) is mentioned as the ordinary tax on imports.

After Rome and Roman territory were overrun by the barbarians, the latter gradually adopted the notions of public policy, including the theory of finance, that had prevailed in the fallen state. In the Dark Ages, the feudal lords individually claimed and exercised the right of imposing transit duties levied on all goods that passed by or through his possessions. Hence, says a recent writer, "the rivers and high-roads were fairly lined with custom-houses and toll-gates." When feudalism gave way to monarchy and a strong central government, the kings merely transferred to themselves the rights that had previously been exercised by the barons. They, too, set custom-houses at all their frontiers, and even on the boundaries of their own different provinces. So universal did these duties, local and national, become, that every continental nation was covered with a net-work of customs lines. Various cities also had their local customs-duties, of which the *octroi* collected at Paris to-day is a survival.

In England we first hear of a tariff for revenue under King Ethelred in or about the year 980. At that time, duties on ships and goods were levied and ordered to be paid at Billingsgate, London. They were first acknowledged as a part of the king's revenue in the reign of Edward I., who received them by regular grant from Parliament, if we accept the assertion of Sir Edward Coke, quoted by Blackstone. But wool, skins, and leather were taxable at the royal pleasure, these being the "hereditary customs" of the crown, known in the law-Latin as *custuma antiqua*. Subsequently under the same king, special duties to be paid by foreign merchants only, were levied (*custuma nova*), being protective in their nature and not merely for revenue. The duty on ordinary goods in this reign was sixpence in the pound, which was raised to one shilling (five per cent.) under Richard II., reduced to sixpence and again raised to eightpence, and finally fixed at the shilling rate, where it remained as late as the ninth year of the reign of William III. (1697). The king also had the right of *prisage*, i.e., of taking from every wine-importing vessel of 20 tuns, two tuns for the royal use. These and other duties were originally granted "for the defense of the realm," and especially for the protection of traffic on the high seas, and were at first given for a fixed period, but to Henry VI., Edward IV., and their successors, for life, until the reign of Charles I. whose unconstitutional levy of these duties without grant of Parliament formed one of the grievances against him. On the restoration of Charles II., the duty was again granted for life, and under William and Mary it was made perpetual and assigned to the payment of the national debt.

In 1663 (under Charles II.), a regular tariff was first established with a book or schedule of rates, which formed the basis of the mode of levying customs-duties for the next century and a half. In 1787 Mr. Pitt proposed the abolition of all the duties then existing, and the substitution of a specific duty on each article, amounting, as nearly as possible, to the aggregate of all the various duties then payable. In fixing the final schedule, it is said that 3000 resolutions were passed by the Houses of Parliament. The act that embodied the results was known as the Consolidation Act. A second important consolidation took place in 1825, when 450 statutes on the subject of the tariff were consolidated and compressed into eleven.

In 1846 an entire revolution took place in England's commercial system, signalized by the abolition of the Corn Laws (q.v.). From that date begins the sway of unrestricted trade in England, one duty after another being abolished, and those that remained being lowered, until in 1891-2, her tariff imposed duties for revenue alone, and that upon less than twenty articles. On the continent of Europe the history of tariff legislation has been somewhat more varied. Restrictions upon freedom of commerce were greater and more oppressive than in England, owing to the much longer

survival of feudal tenures and feudal customs, with the concomitant multiplicity of petty sovereignties, each with his own custom-houses and tariff. In France, at one time, every county had its tolls and import taxes, but these internal restrictions upon trade were swept away at the time of the Revolution. The policy of the country with regard to imports from abroad, however, has varied. Napoleon III., by reason of his English associates, was in theory a free-trader; but France has never fully adopted the free-trade doctrine as held in England. In Germany, the great number of local imposts were gradually abolished by the Zollverein (q.v.), which was established in 1833 by the adhesion of Württemberg and Bavaria to the commercial league formed between Prussia and the Hesses, and now comprising not only all German states, but Luxemburg and a small district of Austria south of Kempfen in Bavaria. The policy of the old Zollverein was one of much liberality regarding the taxation of imports, but in 1880, in accordance with the views of Prince Bismarck, a strictly protective system was inaugurated, designed especially to benefit the agricultural interest. Upon Bismarck's fall in 1890, other influences prevailed, and in 1891 the strictness of the protective regulations was relaxed by admitting Austria-Hungary to a partial membership in the commercial union of the German states, and by considering the removal of the prohibitive duties upon foreign grain and other food products.

HISTORY OF TARIFF LEGISLATION IN THE UNITED STATES. The earliest tariff in the history of the United States was that settled by the first national Congress and approved by President Washington, July 4, 1789. It is interesting to note that the preamble of the act establishing it, states that one of its objects is "the encouragement and protection of manufactures," at this early period laying down a principle afterwards adopted as the tenet of a political party. In 1817, at the beginning of President Monroe's administration, Congress abolished the internal taxes that had been made necessary by the cost of the war of 1812; and in his message the President recommended the imposition of a protective tariff pure and simple. A temporary duty had in 1816 been laid upon cottons and woolens, and this, in deference to the desire of the President, was continued for a period of seven years. The rise of the party of Loose Construction (q.v.), headed by Henry Clay, was favorable to the principle of protection, for the Strict Constructionists held that Congress could only impose a tariff for purposes of revenue, and not for the purpose of fostering particular industries. In 1819, a protective tariff bill passed the lower house, but was rejected by the Senate. The election as Speaker, in 1820, of John W. Taylor, of New York, a declared high-tariff man, gave great encouragement to the Eastern manufacturers, and signalized the increasing influence of the protectionists, though in 1822 the Strict Constructionists were able again to defeat bills embodying the protective principle. In 1824, however, the friends of that principle secured a working majority in Congress, and after a prolonged debate adopted a bill whose essential principle was the exclusion from the American market of such foreign goods as competed with those manufactured in this country. This bill divided the members of Congress on sectional lines—the East, being a manufacturing district, voted almost solidly for the bill, while the South, being agricultural, opposed it, and the Southern members violently denounced it as unconstitutional and unjust, as favoring the interests of one section of the country at the expense of the interests of another section.

In 1827, a convention held at Harrisburg, Penn. (July 30), discussed at length the principle of protection. Only four of the slave-states sent delegates. The result of the convention was a petition addressed to Congress praying for an increase of duties on certain articles then manufactured in the United States, a request which the Secretary of the Treasury brought into general notice in his report of the following December. By this time a strong party had been founded to support the protective system, or the "American System," as it was popularly called. The famous "Tariff of 1828," established by Congress after a debate of six weeks, was the immediate result of this party's propaganda. This went further than any act had previously done in the direction of a prohibitive tariff. The chief articles on which protective duties were laid were woolen and cotton fabrics. At that time the value of the cotton goods annually imported from Great Britain was fully \$8,000,000, and that of woolen goods about the same. The exports to Great Britain, on the other hand, of rice, raw cotton, and tobacco (the chief products of the South), reached the sum of \$24,000,000 per annum. The southern producers naturally feared that if the United States should by a high tariff practically prohibit the importation of a large proportion of the British goods, retaliatory measures might lead to a diminution of the southern exports to Great Britain. It was the discontent felt at the South, with the tariff, that led to the famous nullification movement in 1832, in which year Congress, while modifying the act of 1828, distinctly recognized and retained the protective principle. A State Convention held at Columbia, S. C., on November 19, 1832, formally declared the tariffs of 1828 and 1832 to be "null, void, and no law, not binding upon South Carolina, her officers and citizens." The vigorous action of President Jackson in taking strong military measures to meet this movement by force of arms, was supplemented by an act of Congress known as "An Act for the Enforcement of the Tariff," and popularly styled in South Carolina the "Bloody Bill." But before any actual rupture between the state and the general government occurred, the so-called Compromise Tariff, introduced by Henry Clay, was passed

March 3, 1833. It provided for the gradual reduction of the existing tariff until 1842, after which year the duties on all goods were to be 20 per cent. This measure for the time, allayed the excitement in the South; but by the year 1842, it was seen that the financial consequences of the steady reduction of the tariff were extremely serious, since the government revenues had decreased to such an extent as to be less than the expenses. A new tariff was manifestly necessary, and once again the Strict Constructionists joined battle with the Loose Constructionists. The majority in Congress passed a bill which continued the duties imposed by the tariff of 1833, and provided for the division of any surplus revenue among the states. This was vetoed by President Tyler as being a violation of the compromise reached in 1833. A revenue tariff was also vetoed, because it contained the distributing clause, but on its being again passed, with this clause omitted, the President signed it (Aug. 9, 1842). In 1846 a revenue tariff that eliminated altogether the principle of protection was passed, its aim being merely to provide an adequate revenue for the expenses of the government. A still further reduction of duties was made by the tariff of 1857, which fixed them at the lowest figures shown by any tariff since that of 1816.

In 1861, the Republican party being in the ascendancy, a revolution in the financial policy of the government took place, manifested especially by the "Morrill Tariff," passed in that year, which was intended first of all to protect various American manufactures, with the question of revenue wholly a secondary one. Twice in the same year (Aug. 5 and Dec. 24) the duties were still further increased, this time in order to meet the expenses entailed by the civil war.

The exciting problems that were injected into politics by the war and by the conditions resulting from it, relegated purely economic questions to the background for many years. It was not until 1880 that the further consideration of the protective principle again became an important issue. The election of that year in part turned upon the question of the tariff. The Republicans in nominating Gen. Garfield embodied in their platform a strong declaration in favor of maintaining a scale of duties that should continue to protect American industries against foreign competition. The Democrats began to urge the expediency of modifying a tariff that had been framed to meet the conditions of a time of war, and which, as they claimed, was not merely hampering commerce, excluding the United States from the markets of the world, but fostering monopolies by preventing healthful competition. They therefore declared for "a tariff for revenue only," which was afterwards explained as a tariff that should give "incidental protection." The discussion then begun continued with renewed vigor and with a great increase of public interest. In 1882 provision was made by Congress for the appointment of a Commission to report upon the expediency of a reduction of the tariff. This reduction became a question of pressing importance, since the revenues of the government had so far exceeded its expenses as to accumulate in the Treasury a very large and increasing surplus, which, withdrawn from the channels of trade, threatened a serious disturbance of the financial system of the country. In 1882, the Tariff Commission made its report, and in accordance with its recommendations a bill was passed which did not, however, diminish the revenue as much as had been expected. In 1884, the House being democratic, debated the bill known as the "Morrison Horizontal Reduction Bill" for lowering the tariff, but by a combination between the Republicans and the democratic protectionists led by Mr. Randall, of Pennsylvania, it was defeated. The campaign of that year was largely fought out upon the tariff question, for the democratic platform, while evading the question of protection, demanded a real reduction of tariff duties, as well as legislation to check the aggression of great corporations. The election of Mr. Cleveland appeared to show that the cry of "free trade" had ceased to alarm the great body of the voters, but that they were willing to hear argument upon the questions at issue. The new president's message (Dec. 16, 1885) recommended first of all a reduction of the tariff, and in December, 1887, his message was devoted exclusively to this one topic. In it he stated that the surplus in the Treasury was nearly \$140,000,000, demanded as a remedy the immediate abolition of the duties upon wool and upon raw materials in general, and characterized the existing tariff laws as "vicious, inequitable, and illogical." In accordance with the views of this message a new tariff measure, the "Mills Bill," removing the duty on wool, and aiming at an estimated annual reduction of revenue by fully \$50,000,000, passed the House. The Republican Senate offered a substitute repealing the tax upon tobacco and reducing the duty on sugar one-half, thus securing an estimated reduction of \$65,000,000 per annum. Neither bill became law.

The defeat of the Democrats in the presidential election of 1888 was possibly due to the prominence of the tariff question, but as the majority of the popular vote was on their side, it was seen that a reform or, at any rate, a revision of the tariff was sooner or later inevitable. Therefore the Fifty-second Congress took up the matter in earnest, with the result that the famous McKinley Bill, prepared by Major William McKinley (q.v.), of Ohio, passed both houses of Congress and was signed by President Harrison (Sept., 1890). By its provisions the annual reduction of revenue was estimated to be some \$66,000,000, of which \$6,000,000 was due to a reduction of internal revenue taxes, chiefly on tobacco. It also removed the duties on sugars (if not above 16 Dutch standard), on molasses, needles, and on books printed in foreign languages; and reduced

the duty considerably on beads (ornamental), building stone (rough), pocket cutlery, dye-woods, jute, type-metal, lime, matches, cocoa mats, matting, condensed milk, cut nails, oil-cloths, whale oil, paintings by foreign artists, poultry, shoes, and statuary (marble). The bill was essentially, however, a protective bill, and many of the duties of the old tariff were enormously increased, while some articles (such as aluminium, fans, fruits, eggs, macaroni, pepper, plants, railroad ties, telegraph poles, trees for nurseries, cabinet woods, and tin ore) which the old tariff had admitted free were now taxed. The enforcement of the McKinley bill was followed by a very general rise in prices equal to the advance in the duties.

One very important feature of the McKinley bill was the section added through the influence of Mr. James G. Blaine, then Secretary of State, and known as the "reciprocity section." This provided that whenever the President shall be satisfied that the government of any country producing and exporting sugars, molasses, coffee, tea, and hides, or any such articles, imposes duties upon products of the United States which in view of the free introduction of such sugar, molasses, etc., into the United States, he may deem to be reciprocally unequal and unreasonable, he shall have the power to suspend by proclamation the free introduction into the United States of such sugars, etc., from the country in question. The history of this provision and its practical results will be found in the article RECIPROCITY. See also CUSTOMS DUTIES.

On the return of the Democratic party to power in 1893, an effort was made to carry out its promise of tariff reform. A bill framed by Mr. William L. Wilson (q.v.) passed the House, and after much amendment by the Senate became a law without the President's signature, Aug. 27, 1894. It made a considerable reduction in many duties, admitted wool free, and provided for an income tax. It was still in the main, however, a protective measure.

THEORIES OF THE TARIFF. As stated by way of introduction in this article, a tariff may be imposed solely for revenue without any reference to the protection of a home industry, or it may be imposed chiefly with reference to such protection, or it may be imposed simply to force other countries to lower their own duties in order to secure a modification of those imposed by the tariff in question. Absolute free trade (i. e., the abolition of all duties whatsoever) does not exist in any civilized country and probably never will, owing to the financial necessities of all governments, and the fact that a revenue is easily and surely obtainable from customs duties. Even in England, the government raises annually the sum of £20,000,000 from its tax upon imports. Popular usage, therefore, gives the name of "free trade" to that system which imposes a tariff simply to secure an income for the government, and aims not to protect or foster any industries, but regards a protective tariff as an undesirable and injurious interference with the natural laws of trade. As this question has played so important a part in the political and economic history of the United States, and will undoubtedly continue so to do for many years, it seems best to summarize the arguments for and against the two great systems that divide the allegiance of our economists.

PROTECTION. Protection is the name given to that policy which seeks to promote home industries of any kind by the imposition of duties upon the importation of the products of foreign industry; or by paying such bounties and subsidies to those engaged in the home industries as will give them an economic advantage over foreign producers in the home market. A protective policy to a greater or less extent is adopted by nearly all the great nations of the earth, notably by Germany, Russia, and the United States; while the opposite policy of free-trade is put into actual practice only in Great Britain. By nearly all scientific economists, both in Europe and America, however, protection is regarded as a short-sighted and unwise policy. This variance between the opinion of professed students of political economy and the practice of existing governments is a very curious fact, and gives additional interest to the reasons put forward by the advocates of protection to support and justify that policy. These arguments are, in condensed form, as follows:

(1) *The Equilibrium of Classes.* The active members of the state in its relations to industry are divisible into three classes: the agricultural class, the manufacturing class, and the commercial or trading class. Agriculture, with improved methods and by the use of modern implements, produces a surplus of the food products over and above what the producer himself needs. Hence there remains a large portion of the community not needed in the sphere of agriculture. These naturally divide themselves into (a) a manufacturing class, engaged in supplying the community with comforts, conveniences, and luxuries; and (b) a commercial class, to act as the exchangers of products between the agricultural producers on the one hand and the manufacturing producers on the other. The ideal condition of the State, economically speaking, is reached when, by the law of supply and demand, these classes are in a position of economic equilibrium, when the manufacturers and traders are sufficiently numerous to consume all the surplus the farmer produces. This state of affairs insures a division of labor; it leads the different branches of industry to lean upon one another and to recognize and feel their mutual interdependence and need of one another; and it secures to each class a market near at hand for its products or its services. But foreign interference, which competes with the native industry—which, for example, by underselling the manufactures, drives them out of employment,—disturbs this economic equilibrium, and in so doing to a great

extent deprives the farmer of a market for his goods, and the trading classes of their opportunities to effect exchanges; in other words, it diminishes the number of profitable industries and forces the whole population into some few pursuits which speedily become overcrowded. Protection, by excluding such foreign interference, tends to preserve the economic equilibrium and thus ensures the welfare of all.

(2) *The "New Country" Argument.* This line of argument is rather in support of protection as a temporary than as a permanent system, and to some extent was allowed to be reasonable by no less an authority than the late John Stuart Mill, himself in theory a free-trader. It is neatly put by Professor Robert Ellis Thompson, as follows:

"Were the world in an ideal state of harmony and equality, and were all its peoples equally strong in accumulation of industrial capacity and of capital, in intelligence, and in freedom from burdensome taxation, then the 'let-alone' policy would be the right one. But the actual world is full of inequalities and disadvantages; and experience shows that unrestricted trade between its stronger and richer, and its weaker and poorer countries, puts very great hindrances in the way of the latter. For the former, by an undue concentration of their attention and resources upon manufacturing, can produce a surplus of articles which are easy of transportation, and can be sold in those other countries cheaper than if made there. The individual buyer goes to the cheapest seller; the interest present to his mind is that of spending to the best advantage the money he has in hand. And thus the foreign competition crushes out the home production of all but the rudest and coarsest articles of manufacture, and prevents the establishment of a varied industry, unless the government interfere, as the personification of the nation and its co-ordinating power, to restore the equilibrium by discouraging these imports. Especially is this difficulty experienced in new countries, whose settlers bring with them the Old World's appreciation of modern appliances, comforts, and luxuries, while the home industries needed to supply these wants are still undeveloped. Until such a country has attained a diversified industry, advanced at nearly all points to a full equality with that of the most advanced nations, its manufacturing class are, in the absence of protection, at the mercy of their foreign competitors. If we could consider the citizens of such a country merely as purchasers and consumers of such commodities, then it might seem that they simply gained by free access to the foreign producer. But they have also to produce something to be given in exchange, and find a market for that. 'To buy in the cheapest, and sell in the dearest, market' accessible, is the unreflecting instinct of everybody; but when the former is furnished by the foreigner, it is generally found that the home producer has no 'dearest market' to sell in, but only a 'cheapest' market for that purpose also. And when he reckons up his purchases and sales, or considers his transactions as an exchange of commodities, he will find that he has lost far more than he has gained,—'far fetched is dear bought' the world over. His country may be getting its commodities for the time at cheap rates, but it is bartering for them the very power to produce such commodities—the power to create on its own soil the home-markets whose relative cheapness or dearness will be in favor of all classes."

(3) *The "Varied Industries" Argument.* It is better for a country to have many than few industries, for the following reason among others: Those who produce raw materials—cotton, wool, iron, food—must send them to the great centres of manufacture and consumption, to render them most valuable: the cotton and wool to be spun; the iron ore to be manufactured; the food to be purchased and consumed. Now if these centres of manufacture and consumption are near the sources of production, the producers save the heavy cost of transporting their produce to the point where it is to be made available. In other words, the prices of raw materials and of the manufactured goods approximate most closely in the neighborhood where they are both produced and are mutually exchanged; and hence, if the industries of a country are varied, the prices are equalized to both consumer and producer, to the mutual advantage of each class. Protection keeps in our country the manufactures and mills that take the raw material directly from the consumer, and thus prevents the wide divergence in price between the raw material and the manufactured article.

(4) *The "Independence of Foreigners" Argument.* If any nation becomes dependent upon foreign countries for its supplies of manufactures or for its raw material, a state of war which is always possible, suddenly and remorselessly cuts off the sources of supply and produces great suffering and inconvenience. In 1861-5, the cutting off by blockade of our southern ports from communication with Europe, caused intense suffering in the English manufacturing districts. (See COTTON FAMINE.) In like manner, if we were to become dependent upon Europe for our manufactures, and ourselves only to produce the raw material, a war with a great naval power would at once shut off our sources of foreign supply and produce the greatest possible inconvenience. On the other hand, at the present time, under the policy of protection, we both produce our raw material and manufacture it into goods. We are almost wholly independent of foreigners, and if a complete blockade were to shut us off from all communication with the civilized world for years, we should only miss a few of the luxuries, and scarcely know the difference in other ways. This state of affairs would, of course, not be possible for countries of limited area like England which are forced by natural conditions to look abroad for much that they consume; but the United States possess the great extent

of territory, the diversity of climate, and variety of production necessary for their own maintenance, and it is only the part of wisdom to adopt such an economic policy as will give our citizens the full benefit and enjoyment of all that nature has made available.

(5) *The "Benefit to Farmers" Argument.* If the farmer has to depend on the foreign market for breadstuffs, he is wholly at the mercy of foreign harvests and foreign conditions, as well as upon local circumstances. Moreover, he must spend a large portion of his returns in getting his goods to market. Under the operation of free-trade this would be his condition. While it is true that he would then be able to purchase manufactured articles at lower prices, his own income would not only be diminished by the transportation-tax upon his products, but it would be much more uncertain and precarious. Under a protective system, however, the farmer has, near by, communities engaged in manufacturing, who steadily purchase and consume the food that he has to sell. In other words, under protection, the American farmer has two markets for his produce, and one of them is at his very doors; while under free-trade he must largely depend upon the uncertain needs of foreign countries, and suffer the continual competition of those of his own countrymen who, being unable to engage in manufacturing pursuits, must of necessity betake themselves to agriculture. At the present time, of the wheat shipped from the West, only about one-sixth is exported to Europe, the rest being consumed in our own country. Of course if the time should ever come when our country produces only enough for its own use, then protection would be of no great benefit to the farmer, for he would in any case be certain of a market for his goods: but at the present time, and in all probability for many years to come, the production of our breadstuffs will far exceed what is necessary for home consumption.

(6) *The "Labor Market" Argument.* The diversity of industries secured by the principle of protection, is particularly advantageous to those who gain their living by manual labor, and who, as it is said, "have labor to sell." A variety of industries causes competition among the employers of labor, and this competition naturally enhances the wages paid to the workingmen. It is found to be universally true that where one industry is wholly, or almost wholly, dominant over others, there the rate of wages is a low one. In Ireland, where agriculture is almost the only pursuit, in North Belgium, and in the agricultural districts of England, wages are disproportionately low compared with the prevailing standard in the districts where manufactories are numerous. Furthermore, in agricultural communities, only the labor of able-bodied men is in much demand, and skill, ingenuity, and intelligence, unless coupled with bodily strength are underpaid and little valued. But when the industries are varied, there exists a demand for every kind of labor — for that of boys and women, as well as for that of men; and skill and dexterity are highly prized. In such communities we have all the members performing a useful part, instead of a few laboring and the rest living in idleness on the proceeds of their industry.

(7) *The Historical Argument.* History shows us that in our own national development, prosperity and activity both financial and intellectual, have invariably followed the stimulus given to manufactures by a protective tariff. Until Maine began to use her water-power and to establish mills, her people were restricted to agriculture and lumbering, and were conspicuous for their poverty and lack of progress. So, too, in the years between 1833 and 1842, throughout the whole country, money was scarce, and while food was plenty, comforts were difficult to procure, and the life of the people was crude and bare. For a variety of employment not only stimulates the general prosperity of any people, but quickens their intellectual activity by giving full play to their ingenuity, by encouraging their inventiveness and resourcefulness, and rewarding their mechanical skill. The American people have now a high place in the history of invention by the brilliant discoveries of Eli Whitney, and Fulton, and Morse, and Edison; and the direct encouragement to these discoveries was the rich reward held out to inventive genius through the spirit of protection, which, as the history of tariff legislation shows, almost from the first received the significant name of "the American System."

FREE TRADE. It must again be stated that by the term "free trade," in this country, at least, is meant not the total abolition of all customs duties, but the restriction of those duties to the single purpose of providing revenue for the government, and without regard to the protection or assistance of any native industry. The chief arguments advanced by the American advocates of free trade are as follows:

(1) *Free Trade is a Natural Right.* No one questions that the simplest and most obvious of the natural rights possessed by the individual is the right of free exchange. That right is simply a permission to make the best possible use of his experience and judgment in purchase or sale, with the object of making such means as he possesses secure to him as much as possible in the exchange that he makes. Free exchange is only one of the many aspects of personal liberty. A man by hard physical or intellectual labor earns a certain sum of money. Natural right would allow him to spend it where its purchasing power is the greatest; it would give him the power of making the best bargain possible. The system of free trade simply recognizes this natural right. It says to all: "Buy where you can buy cheapest; spend your hard-earned money where it will buy the most." On the other hand, the protective system says: "You must not be allowed to exercise your judgment and experience in buying and selling.

You must, for the benefit of a few manufacturers, buy where goods are dearest, and where you will get the least return for your money." Protection thus assumes to make a man's bargains for him, to direct the employment of his capital, and to prevent him from disposing of his labor and the fruits of it, to the best advantage.

(2) *Free Trade is Fairest to all Classes.* Protection can only be effectual by being partial. For if all classes were equally protected, the prices of all goods would rise equally, and the relative position of affairs would not be changed. If, in other words, all producers received protection, foreign trade might cease, and so far as concerns home-trade, every one would pay more than he would have given had trade not been protected. Such a system, says Prof. Thorold Rogers, prevails in Munich, so far as manufacturers go, where every artisan belongs to some guild or other, and, in consequence, all manufactures in that city are bad and dear. Protection, then, in its very essence, is protection of *some* occupations rather than *all* occupations; and by shutting out competition in these occupations, it raises artificially the prices on the products of these occupations, thus constituting a tax which must be paid by all consumers. Hence, protection establishes favored classes in the community and is in consequence essentially unfair. Free trade, on the other hand, treats all classes and all occupations exactly alike, imposing no restrictions at all.

(3) *Free Trade secures to Capital its most productive Employment.* If capital in any country flows of its own accord into any industry, it is clear that such an industry needs no protection. It is because, under particular circumstances, capital is not so advantageously employed in certain callings that the State attempts to divert capital from a more productive to a less productive channel. If protection is needed to sustain a manufacture, the very act implies that, without this assistance, the trade would be carried on at a loss; in other words, it would not be carried on at all. Tea and coffee could perhaps be cultivated in hot-houses if the legislature of any country resolved on protecting such an industry by restraining foreign importation. Of course such an act would be madness, as the produce would cost probably fifty times as much on the adoption of such means. But there is only a difference in degree between such an expedient and that of a protective duty on corn, or iron, or tin, except that, in so far as the use of these latter articles is necessary, the loss and the mischief are the greater.

(4) *Free Trade admits of a Variety of Industries, especially in the United States.* Every country enjoys a *natural protection* to its manufactures. When the article is cheap and bulky, the cost of carriage is equivalent to a prohibitive duty; when it is cheap and light, the same element of cost, amounting to a considerable percentage, is a protective impost. In the great majority of cases this charge, and similar incidents attached to foreign commerce, are abundantly sufficient to give a legitimate stimulus to home production. That "trial under a new set of conditions," if the expression means anything at all in relation to manufactures, a notion which one may reasonably take the liberty to dispute, is best satisfied when the conditions are those of remoteness from the foreign market, and uncertainty of supply or cost.

Besides, the reasons which can be alleged against the diversion of capital from more profitable into less profitable channels, which is the necessary result of protective regulations, apply with overwhelming force to young and rising nations, that is, to communities whose territory is imperfectly occupied. Such societies almost invariably suffer from a dearth of capital. The natural resources of the community are so vast, so undeveloped, so unappropriated, that most of those persons who constitute the community in question can employ every particle of capital productively and are eager to obtain more. The rate of interest in young countries is always high, for lenders are scarce, borrowers numerous. It is the height of folly, then, to starve such capital as does exist by wasting a portion of it in occupations or employments which are imperfectly productive, and which need, despite the natural advantages attached to home-production, the artificial assistance of legislative protection in order that they may exist.

There is an argument constantly alleged in favor of a protective system, which is not so much economical as political or social. It is a favorite practice, especially with the protectionist orators, and partisans in the United States, to insist that it is the duty of government to do its best to develop all industries; not so much in order that the country may be relieved from the necessity of depending on the foreign producer, as that the employments of the citizens should be as varied and the nation as self-contained as possible. We do not want, these people say, to have the whole community engaged in the production of raw materials; we want manufacturers as well as farmers, artisans as well as agriculturists. It has been already said that they must have this variety from the natural protection afforded to all countries in consequence of their distance from the foreign market. If the importation of foreign goods into the United States were wholly free, or at least if no duty were imposed on foreign products in excess of taxes at home, the Pennsylvanian or New England manufacturer would still enjoy great advantages over the foreign importer in the markets of Illinois, Missouri, and Ohio, because he is several thousand miles nearer to his customer, and can be much more easily informed of his customer's wants.

(5) *Protection, by preventing healthy competition, fosters Monopolies.* One very impor-

tant practical objection to the adoption of a protective system is the difficulty of deciding honestly what particular industries shall receive protection ; and again of determining when the protection is to cease. In 1861 our American manufactures were described as "infant industries," and protection was asked for them ; but now, in 1891, after thirty years of protection, an even higher tariff is established, although the original plant has been put in and paid for hundreds of times over, and the value of the goods manufactured is more than \$8,000,000,000 per annum, while in many foreign markets, American goods are actually underselling those of foreign producers. It is clearly manifest, and the history of American protection proves the assertion true, that in selecting the favored industries, in determining the proper amount of protection, and in prolonging the term of protection, there is room for every possible form of intrigue, of political corruption, and of sectional discrimination ; so that in the development of the system, the massing together of great interests forms a powerful means of demoralizing the legislative body whose function it is to make or modify these concessions. By reason, partly of partisan influences, partly because of misrepresentation by those most interested, and partly because of ignorance or indifference, the tariff rate has often laid a far heavier duty upon foreign products than what was necessary to prevent them from underselling the corresponding American goods. It has been made so high as to shut out any competition whatsoever, and has allowed the native manufacturer to place an unduly high price upon his wares, which the general consumer has to pay because he has no choice. Protection has often, in fact, worked to the disadvantage of the American consumer and to the benefit of the foreigner. In June, 1891, attention was publicly called to a firm of opticians in Philadelphia who were selling in London certain lenses at a price 20 per cent. cheaper than that at which they sold them in Philadelphia. Being protected by a heavy tariff, they feared no competition in the United States, and so put up their prices in selling to their own countrymen. If, after paying the cost of transportation to England, they could compete with Englishmen, they would scarcely seem to be in need of protection at home ; yet probably these same manufacturers would declare themselves ruined if a committee of Congress were to propose the abolition or reduction of the duty on these lenses. And what is true of this one industry is true of many others. American firms to-day are selling goods in Europe and in Canada at prices lower than those asked of their own countrymen. Thus, in many cases, the protective tariff protects the foreigner at the expense of the native consumer. Perhaps the most widely reaching danger of the protective principle is this : that it prevents competition and fosters the growth of the monopolies and trusts (see TRUST), which during the past ten years are overshadowing the smaller industries and concentrating enormous aggregations of capital in the hands of a comparatively few men. The social dangers resulting from this state of things are growing more and more plain with every year, and the widespread dissatisfaction that is beginning to prevail has an ominous tendency to threaten, at least remotely, the security of all capital and the sanctity of private property.

(6) *Free Trade does not lower Wages.* This is a truth that is not generally admitted by protectionists, the theory being in general that protection by raising prices, generally raises wages as well, while free trade puts everything "on a cheap basis." But wages are subject to many other laws, and it is a fact not generally known that of the different countries of Europe, England, the only free-trade country, pays its workmen the highest wages ; and Germany, where a high protective tariff prevails, pays its laborers the lowest. Furthermore, in England itself, higher wages prevail now than were paid fifty years ago under the old protective system. Again, it is a mistake to suppose, as so many do, that increasing the cost of articles by means of a tariff, increases the wages of the laborers engaged in making them. What is really increased is the profit of the manufacturer who furnishes the capital, while the workingman not only secures no more than before, but actually less by reason of the increased cost of living. Under the new McKinley tariff the cost of the following articles, that are used by every workingman, has been largely increased, while wages certainly have not risen since the tariff went into effect : blankets, brushes, buttons, clocks, cotton trimmings, cotton handkerchiefs, cotton hosiery, cutlery, eggs, felt hats, flannels, glassware, knit-goods, oatmeal, rubber overshoes, cotton thread, tinware, lamp-wicks, worsted yarns, and woolen manufactures. The result has simply been to enhance the profits of the protected manufacturer and to increase the cost of living to all other persons, the workingman included.

(7) *Free Trade is economically desirable,* for it is the natural law of the community ; it is consistent with the liberty of the individual to purchase in the most advantageous market ; it allows capital to flow into the most productive channels instead of forcing it into artificial and unnatural directions ; it does not tax the many to benefit the few ; it permits and encourages competition and prevents monopolies ; and finally it allows the complicated questions of trade and commerce to work out their own natural and simple solutions, without the unwise, interested, and often purchased interference of political bodies.

FAIR TRADE. This is a term that has of late come into vogue in England to describe a system advocated by some statesmen, and having the same meaning as the American term Reciprocity (q.v.).

TARIM RIVER. See TURKISTAN.

TARIN. See ABERDEVINE.

TARLATAN, a thin, gauze-like fabric of cotton, used for ladies' ball-dresses, etc. It is usually dyed or printed in colors. Tarare, in France, is the chief centre of this manufacture, whence it is largely exported. Switzerland alone competes with France in the production of tarlatan, but those of the latter country far surpass the former in fineness.

TARLETON, Sir BANNASTRE, 1754-1833; b. England; a lieut.col. in the army of Cornwallis during the revolutionary war. At the head of a loyalist force known as "the British legion," he inflicted considerable damage upon the Americans in the south. He massacred Col. Buford's regiment at Waxhaw creek, 1780, but was defeated the next year, near Cowpens, by Gen. Morgan, with a smaller force. He was with Cornwallis till the end of the war. He was elected to parliament in 1790, and made maj.gen. in 1817. He wrote a *History of the Campaigns of 1780 and 1781 in the Southern Provinces of North America*.

TARLETON, RICHARD, an English actor and dramatic writer of the time of Queen Elizabeth, said to have been born in Shropshire. He excelled in comic parts, and, besides, won much reputation for his extemporaneous jests, so that his name was used for many years to account for the paterfity of many current jokes, as was later the case with the name of "Joe Miller" (q.v.). A collection of these jests was made at the time, and has been reprinted in part during the last ten years in London. Many of them seem to modern taste pointless or silly, and many others simply obscene. Tarleton won the favor of the queen, who even made him a groom of the Chambers. He is known to have written at least one play, *The Seven Deadly Sins*, which has been lost. He died in 1588.

TARN, a department in the s. of France, bounded on the n. by the departments of Aveyron and Tarn-et-Garonne, receives its name from the river Tarn. Area, 2317 sq.m.; pop. '96, 339,827. The surface is in general elevated, and in the s. and s.e. are the montagnes Noires and the monts de l'Espinois, branches of the Cévennes. The principal summit, the Rock of Montalet, is 4430 feet high. The surface is well wooded, and there are extensive vineyards. The chief river, the Tarn, an affluent of the Garonne, has a course of 235 miles. Albi is the capital.

TARN. A word borrowed from the Icelandic *tiörn*, and properly applied to a small mountain lake, but in common usage given also to any dark pool or still body of water.

TARN-ET-GARONNE, a small department in the s. of France, bounded on the s.e. by the department of Tarn. Area, 1436 sq. m.; pop. '96, 200,390. The principal river is the Garonne, which flows n.w., and its affluents, the Tarn and Aveyron. The surface is marked by plateaux, about 1000 ft. in average altitude; the highest hills do not rise above 1600 feet. The climate is beautiful, healthy, and temperate. Cereals are raised in great quantities. There are manufactures of paper, silk, and soap, and much wine is produced. The department is divided into the three arrondissements of Montauban, Castelsarrasin, and Moissac. Montauban is the capital.

TARNOPOL, a t. of Austria-Hungary, in Galicia, charmingly situated on the left bank of the Sered, 73 m. e.s.e. of Lemberg. There are manufactures of leather and soap, and a considerable trade. Pop. '90, commune, 27,405.

TARNOW, a t. of Austria-Hungary, in Galicia, near the right bank of the Dunajec, a navigable tributary of the Vistula, and 47 m. e. of Cracow. It has a fine cathedral. Pop. '90, commune, 27,574.

TARPAULIN, a large sheet of the coarsest kind of linen or hempen cloth, saturated with tar to render it waterproof. It is used for covering loaded wagons, the hatchways of ships, and similar things, as a temporary protection from wet.

TARPEIAN ROCK (Lat. *Rupes Tarpeia*, or *Mons Tarpeius*), the name originally applied to the whole of the Capitoline hill (see CAPITOL), but latterly confined to a portion of the southern part of the hill, the following being the legend commonly related in connection with it. In the time of Romulus, Tarpeia (a vestal virgin), the daughter of Sp. Tarpeius, governor of the Roman citadel on the Capitoline, covetous of the golden ornaments on the Sabine soldiery, and tempted by their offer to give her what they wore on their left arms, opened a gate of the fortress to the Sabine king, Titus Tatius, who had come to revenge the rape of the Sabine women. "Keeping their promise to the ear," the Sabines crushed Tarpeia to death beneath their shields, and she was buried in the part of the hill which bears her name. Subsequently it was not unusual for persons condemned on the charge of aspiring to restore the monarchy, or of treason to the state generally, to be hurled from the Tarpeian rock—e.g., the famous Manlius, the savior of the capital during the invasion of the Gauls.

TARQUINI, CAMILLO, 1810-74; an Italian Jesuit of noble family; joined the society of Jesus in 1837, in 1850 became professor of Canon law in the Collegium Romanorum, and in 1873 was made cardinal-deacon. He published *Juris Ecclesiastici Publici Institutiones* (1862), and several monographs.

TARQUINIUS, the family name of two kings of Rome, with whose history, or rather with the legends regarding whom, the fortunes of the city are closely interwoven. The story goes that Demaratus, a Corinthian noble, emigrated from Greece, and settled at Tarquinii, in Etruria, where he married an Etruscan wife, by whom he had two sons, Aruns and Lucumo. Aruns died during his father's lifetime, but Lucumo married into one of the noblest Etruscan families. His wife, named Tanaquil, was a bold, ambitious and wise woman. By her advice, Lucumo resolved to go to Rome. He set out, accompanied by a large train of followers, and as he approached the Janiculum, an eagle swooped down, and snatching off his cap, carried it up to a great height, then descending, placed it on his head again. Tanaquil, who was deeply skilled in the science of augury, prophesied from this omen the highest honors for her husband, who was hospitably received at Rome, and soon after admitted to the rights of citizenship, whereupon he took the name of L. Tarquinius, or, according to Livy, L. Tarquinius Priscus. The Roman monarch, Ancus Marcius, appointed him guardian of his children; and on the death of the former, the senate and the citizens unanimously elected him to the vacant throne. His reign was a glorious one. Against the Latins, Sabines, and (according to Dionysius) the Etruscans, he waged successful war, forcing the whole of the twelve sovereign cities of Etruria to recognize his supremacy, and do him homage. But the works that he executed at home are even more renowned than his exploits abroad. To L. Tarquinius Priscus (*Priscus* is commonly translated the "elder;" but Niebuhr objects to this translation as involving an anachronism, and notices the fact that *Priscus* is a common cognomen among the Romans) are ascribed the construction of the magnificent *Cloaca*, or sewers (see, however, CLOACA MAXIMA), which remain uninjured to this day; the laying out of the circus Maximus and the Forum; the institution of the great or Roman games; and (some say) the building of the Capitoline temple (see CAPITOL). The legend also represents him as effecting certain political and sacerdotal changes. See ROME. Tarquinius was assassinated after a reign of 38 years, at the instigation of the sons of Ancus Marcius, who considered themselves as best entitled to the throne, and dreaded lest he should use his influence to get his favorite and son-in-law, Servius Tullius, chosen as his successor. But their crime did not avail them, for, through the dexterity of Tanaquil, Servius was elected to the vacant throne, and signalized himself not only by his military exploits, but also by great organic changes in the Roman constitution (see article ROME for an account of the "Servian reform"). Tarquinius left two sons, L. Tarquinius Superbus and Aruns, both of whom married daughters of Servius Tullius; and two daughters, one of whom married Servius Tullius himself and the other M. Brutus, by whom she became mother of L. Brutus, first consul of the Roman republic.

L. TARQUINIUS SUPERBUS, son of the preceding, having murdered his father-in-law, Servius Tullius, at the instigation of his wife, is represented in the legend as audaciously usurping the vacant throne; but as the whole drift of his legislative policy was to abolish the reforms of Servius, there can be little doubt that the real significance of this part of his career lies in the fact that it indicates a successful reaction, on the side of the patricians, against the more liberal and progressive policy of the preceding age. That the younger Tarquinius, at least, is a historical character, seems to be pretty generally allowed. The incidents of his career are so numerous and coherent, and the impress of his name and character is so deeply stamped on the national memory, that he cannot be regarded as a wholly imaginary personage. Analyze the story how we may, there will always remain a residuum of insoluble fact, not essentially at variance with the character of the tragic tradition. As far as we can gather from the ancient annals, the usurpation of Tarquinius was probably achieved by the help of an enterprising section of the nobles, who clung tenaciously to their privileges, and could not endure the constitutional recognition of the *plebs*. It does not appear that the whole of the senators connived at or even approved of Tarquinius's procedure. We are expressly told that he drove numbers of those whom he mistrusted into exile; in other words, he persecuted and banished the adherents of the Servian policy of conciliation. Like a Turkish tyrant, he surrounded himself with a body-guard—another indication of the original insecurity of his position, and strengthened himself by foreign alliance, marrying his daughter to Octavius Mamilius, prince of Tusculum. By means of subtle and unscrupulous intrigues he obtained or consolidated the Roman hegemony in Latium; offered sacrifice in the name of all the Latins at the Alban mount; fused the contingents of the latter with the Roman legion; put to death as traitors such of their chiefs as opposed him (e.g., Turnus Herdonius); and, at the head of the combined forces, penetrated into the Volscian marshes, and subdued the natives. On his return he completed the building of the capitol, which the elder Tarquinius had begun, and deposited in the vaults the Sibylline books he had curiously acquired. See SIBYL. He next conquered the town of Gabii (where many of the banished nobles had found shelter), through an elaborate stratagem, in which his son Sextus played the principal part. But his lavish expenditure both in war and peace necessitated the imposition of heavy taxes, and murmurs of discontent were heard among the people. The patience both of plebs and patricians was beginning to give way. Coincident with this state of things a fearful omen was beheld: from the altar in the royal palace crept forth a serpent, and devoured the entrails of the victim. Tarquinius sent two of his sons, Titus and Aruns, to Delphi to consult the oracle. They were accompanied by their cousin, L. Junius Brutus (q.v.), who had long feigned himself a fool in order to save his life, for Tarquinius had killed his father and brother in order to possess himself of their great wealth. On their return they found that the king had opened war upon the Rutuli, and was besieging Ardea, whereupon they joined the Roman camp. Here occurred, between Sextus and Collatinus, the famous dispute about the virtues of their respective wives, which led to the rape of Lucretia. The details of this legend are so familiar that it is unnecessary to recount them. Suffice it to say that it roused such a storm of indignation that the people of Collatia (where the shameful deed was done) rose in arms, and renounced their allegiance to Tarquinius. Brutus carried the news to Rome, and the senate, fired with a righteous anger, deposed the tyrant; finally, the army before Ardea also revolted. Tarquinius and his sons were obliged to flee, and an aristocratic republic was constituted at Rome. Three different attempts were made to restore Tarquinius by force: first, by his own Etruscan kinsmen of Tarquinii; second, by Lars Porsena (q.v.) of Clusium; and third, by his son-in-law, Octavius Mamilius, "prince of the Latian name," all of which, according to the legend, failed; and at length Tarquinius, utterly baffled and beaten, retired to Cumæ, where he died, a wretched and childless old man, for all his sons had met death before him.

TAR RAGON. See ARTEMISIA.

TARRAGO'NA, a province in n.e. Spain, part of the ancient division of Catalonia or Cataluna, lying on the Mediterranean and adjoining the provinces of Teruel, Saragossa, Barcelona, Castellon, and Lérida, drained by the Ebro and a few streams of little importance; 2451 sq. m.; pop. '87, 348,579. There is much mountainous surface, the Prades range crossing the province from n. to s.; but the valleys and lower slopes are very rich in soil and covered with vineyards, from which excellent wine is produced; other exports are brandy, cork, silk, velvet, and woolen and cotton goods. Capital, Tarragona.

TARRAGO'NA, a seaport of Spain, capital of the modern province of the same name, stands on the Mediterranean shore, at the mouth of the Francoli, 60 m. w. of Barcelona. It consists of two portions—the upper (the ancient) and the lower (the modern) towns. The former stands on a hill 720 ft. high, and is girdled with ramparts. The lower town, completely separated from the higher by a line of works, is regular and open, and is defended by two forts. The beautiful cathedral, in Gothic and Norman, and which dates from the middle of the 12th c., is the principal edifice. There is an interesting antiquarian museum, rearranged in 1868. There is a growing trade in grain, wine and oil; and fruit is largely exported. The harbor is safe for the vessels that visit Tarragona. Pop. '87, 27,255.

Tarragona, called by the Romans *Tarraco*, was founded by the Phenicians (who called it *Tarchon*, citadel), and afterward became the capital of the Roman province of Tarracensis. Among the Roman antiquities are the remains of an amphitheatre, which has been used as a quarry; a magnificent aqueduct, 96 ft. high and 700 ft. long—still in use—and near the town the tower of the Scipios, much decayed. Tarragona was taken and cruelly sacked, in June, 1813, by the French under Suchet.

TARRANT, a co. in n.e. Texas; 900 sq. m.; pop. '90, 41,142. Co. seat, Fort Worth.

TARRYTOWN, a village in Westchester co., N. Y.; on the Hudson river and the New York Central and Hudson river railroad; 27 miles n. of New York. The Hudson at this point has a lake-like expansion called the Tappan Zee, and Tarrytown, which is built on the side of a hill, commands an extensive view. It is noted as the scene of the capture of Major André and as the burial-place of Washington Irving. Sleepy Hollow is included in its precincts. The village has many objects of general interest, a Revolutionary soldiers' monument, Irving institute, Y. M. C. A., and Y. M. Lyceum libraries, national bank, manufactories of shoes, tiles, and plumbers' tools, and weekly newspapers. Pop. '90, 3562.

TARSHISH, probably the same as *Tartessus*, a city and emporium of the Phenicians in Spain, somewhere near the mouth of the Guadalquivir. It is frequently mentioned in Scripture, notably so in connection with the prophet Jonah, who took ship for Tarshish, when he sought to "flee from the presence of the Lord."

TARSIA-WORK, a beautiful kind of marquetry made in Italy. It is produced by inlaying pieces of colored wood so as to represent figures and landscapes. That of Sorrento is very celebrated; and lately, many fine pieces of this work have been made in Perugia. It is usually applied to the decoration of cabinet-work.

TARSUS, anciently the chief city of Cilicia, and one of the most important in all Asia Minor, situated on both sides of the navigable river Cydnus, in the midst of a beautiful and productive plain, and about 18 m. from the sea. It was a great emporium for the traffic carried on between Syria, Egypt, and the central region of Asia Minor. In the time of the Romans, two great roads led from Tarsus, one n. across the Taurus by the "Cilician Gates," and the other e. to Antioch by the "Amanian" and "Syrian Gates." Tarsus, judging from its name, was probably of Assyrian origin; but the first historical mention of it occurs in the *Anabasis* of Xenophon, where it figures as a wealthy and populous city, ruled by a prince tributary to Persia. In the time of Alexander the Great, it was governed by a Persian satrap; it next passed under the dominion of the Seleucidæ, and finally became the capital of the Roman province of Cilicia. At Tarsus, Anthony received Cleopatra, when she sailed up the Cydnus, with magnificent luxury, disguised as Aphrodite. Under the early Roman emperors, Tarsus was as renowned for its culture as for its commerce, Strabo placing it, in respect to its zeal for learning, above even Athens and Alexandria. It was the birthplace of the apostle Paul, who received the greater part of his education here; and here the emperor Julian was buried. Gradually, during the confusions that accompanied the decline of the Roman and Byzantine power, it fell into comparative decay; but even yet, it is—under the name of *Tarso* or *Tersus*—the most considerable place in the s.e. of Asia Minor, has a pop. of about 10,000.

TARTAN, or **PLAID**, a pattern woven in cloth, in which bands of different colors are woven or printed side by side, both the warp and weft way of the material, thus giving the well-known checkered pattern. This is probably the oldest pattern ever woven; at all events, the so-called shepherd's plaid of Scotland is known to have a very remote antiquity among the eastern nations of the world. The plaid pattern admits of a very great variety of modifications, by the introduction of different colors, and by varying the amount of each color employed. These colored plaids were in great favor in the Highlands of Scotland, where each clan wore a particular kind as its distinctive dress.

TARTAR, a mixture of bitartrate of potash and tartrate of lime (see **TARTARIC ACID**), is a deposit formed from wine, and known in its crude form as argol (q.v.). About 900 tons annually of this substance are imported into Great Britain, from the chief wine-producing countries of Europe and the cape of Good Hope.

The word *Tartar*, which gives the name to tartaric acid, is derived from the Greek *Tartaros*, hell. "It is called *Tartar*," says Paracelsus, "because it produces oil, water, tincture, and salt, which burns the patient as Tartarus does."

TARTAR, CREAM OF. See **TARTARIC ACID**.

TARTAR, FOLIATED EARTH OF, an old name for acetate of potash, in consequence of the foliated satiny masses in which that salt occurs.

TARTAR, SOLUBLE, a term applied by some chemists to neutral tartrate of potash, and by others to borotartaric acid. See **TARTARIC ACID**.

TARTAR OF THE TEETH is a deposit of salts of lime and organic matter from the saliva, and usually occurs most abundantly on the inferior incisors. If it is suffered to accumulate, it causes inflammation and absorption of the gum, and gradual loosening of the teeth. The accumulating of this substance may usually be prevented if due attention is paid to the cleaning of the teeth. "The teeth," says Dr. Druitt, "should be cleaned at least twice a day with a soft tooth-powder (precipitated chalk is best) and a little soap. The hairs of the tooth-brush should be soft, and not too closely set, so that

they may penetrate the better into the interstices of the teeth." When the tartar has accumulated to any extent, it must be removed by the *scaling instruments* of the dentist.

TARTARIC ACID. Ordinary tartaric acid, $C_4H_6O_6$, is usually seen in the form of colorless, transparent, oblique, rhombic prisms, which are not affected by the action of the air, have an agreeable acid taste, and are soluble in water and alcohol. The crystals when gently warmed become strongly electric, the opposite sides of the crystals exhibiting the opposite forms of electricity. On heating tartaric acid to about $275^\circ F.$ ($135^\circ C.$), it fuses; and at a slightly higher temperature it becomes changed, without losing weight, into an isomer, *metatartaric acid*. On further heating to about $302^\circ F.$ ($150^\circ C.$), two molecules of the acid lose one equivalent of water, and *tartralic acid*, or *ditartaric acid*, $C_8H_{10}O_{11}$, is formed. If the temperature be raised to $356^\circ F.$ ($180^\circ C.$), half the basic water is expelled, and *tartralic acid*, $C_8H_8O_{10}$, is formed; and finally, all the basic water is driven off, and *anhydrous tartaric acid*, or *tartaric anhydride*, $C_4H_4O_6$, remains in the form of a white porous mass insoluble in water, alcohol, or ether. If, however, it be allowed to remain long moist, it gradually becomes converted into crystallized tartaric acid. Finally, on distilling tartaric acid in a retort at a temperature of $400^\circ F.$ ($204.5^\circ C.$) and upward, it is decomposed into certain gases and empyreumatic oily matters, water, and acetic, pyruvic (or pyracemic) and pyrotartaric acids.

Oxidizing agents, such as peroxide of lead or nitric acid, readily act upon tartaric acid, and convert it into formic and carbonic acids; and when fused with caustic potash, it splits up into acetic and oxalic acids. It is one of the strongest of the organic acids.

This acid occurs abundantly in the vegetable kingdom both in the free and combined state. It is found as a free acid in tamarinds, grapes, the pine-apple etc.; and in combination with potash and lime in tamarinds, grapes, mulberries, and the unripe berries of mountain-ash, and in small quantity in the juice of many other vegetables. It is, however, from argol (q.v.), a product of the fermentation of grape-juice, that the tartaric acid of commerce is obtained. The details of the process may be briefly described as follows: argol, or crude bitartrate of potash, is dissolved in boiling water, and chalk is added as long as effervescence occurs. An insoluble tartrate of lime is precipitated, and tartrate of potash remains in solution. This tartrate of potash is converted by the addition of chloride of calcium into insoluble tartrate of lime and soluble chloride of potassium. The tartrate of lime obtained by these two operations, if treated with sulphuric acid, readily yields free tartaric acid in solution, with sulphate of lime as a precipitate. The filtered liquid, when cooled and evaporated, yields tartaric acid in crystals.

Tartaric acid is used in large quantity by calico-printers and dyers for the removal of certain mordants, and is much employed in medicine in the preparation of effervescing draughts and for other purposes.

Tartaric acid being bibasic, can form both acid and normal (or neutral) salts, according to the two general formulæ, $M.H.C_4H_4O_6$, and $M_2.C_4H_4O_6$, when M signifies any monad metal. The normal salts may contain (1) two similar or (2) two different protoxides, or (3) a sesquioxide, or (4) a protoxide and a trioxide; as, for example—(1) Normal potassium tartrate, $K_2.C_4H_4O_6$; (2) Sodium potassium tartrate, also called Rochelle salt, $NaK.C_4H_4O_6$; (3) Ferric tartrate, $Fe_2(C_4H_4O_6)_3$; (4) Potassio-antimonious tartrate, or tartar emetic, $2K(SbO)C_4H_4O_6 + H_2O$. The tartrates are for the most part formed by partially or entirely saturating the free acid with an oxide or carbonate, or in the case of neutral tartrates containing two oxides, by saturating a solution of the bitartrate of one oxide with the other oxide. The most important tartrates are the following:

Normal potassium tartrate, $K_2.C_4H_4O_6$, a soluble salt, which crystallizes with difficulty, and is formed in preparing tartaric acid from *bitartrate of potash*, $KHC_4H_4O_6$. This salt is prepared from argol by extraction with boiling water, which dissolves about one sixth of its weight. As it is much more insoluble in cold water, of which it requires 240 parts, it crystallizes readily as the hot solution cools. The snowy white rhombic prisms which are thus deposited constitute *cream of tartar*. When heated to redness in a covered crucible, a charred mass, consisting of carbonate of potash and charcoal in a fine powder, remains, and is used in the laboratory for reducing operations under the title of *black flux*; and if cream of tartar is deflagrated with twice its weight of niter, *white flux*, also a reducing agent, consisting solely of carbonate of potash, is obtained. *Sodium potassium tartrate* has been already described in the article ROCHELLE SALT. *Potassium ferrous tartrate*, or *ferrum tartaratum*, $K_2Fe(C_4H_4O_6)_2$, and *ammonio-tartrate of iron*, or *ferrum ammoniac tartras*, $(FeO)_2.(NH_4)_2.(C_4H_4O_6)_2$, although the latter is not included in the pharmacopœia, are excellent medicinal preparations of iron. For the method of preparing them, the reader is referred to Neligan's *Medicines*, 6th ed., p. 658, etc. They occur in the form of brilliant, semi-transparent, reddish-brown scales, and are soluble in about their own weight of water at $60^\circ F.$ *Potassium tartryl borate*, known also as *soluble tartar* (although the term has also been applied to tartrate of potash), or *soluble cream of tartar*, $K.BO.C_4H_4O_6$, has been employed medicinally, but is not now used. *Potassio antimonious tartrate*, known also as *tartarized antimony* and *tartar emetic*, $2K(SbO)C_4H_4O_6 + H_2O$, is one of the most valuable articles in the whole

Materia Medica. This salt, obtained by a process which is given in the pharmacopœia, occurs in the form of square prisms, which are soluble in about 15 parts of cold water and in 2 parts of boiling water. This salt is somewhat efflorescent, and when dried at 212° F. (100° C.) loses all its water of crystallization; its solution slightly reddens litmus, throws down an orange-colored sulphide of antimony, if a current of sulphureted hydrogen is passed through it, and has a very peculiar nauseous, metallic taste.

There is no very delicate test for tartaric acid. Its presence in a moderately strong solution may be detected by the addition of acetate of potash, when a sparingly soluble bitartrate is soon separated, especially if the mixture be well stirred. All the tartrates on charring emit a peculiar odor resembling that of burned sugar.

A remarkable metameric modification of tartaric acid is known as *racemic* or *paratartaric acid*, $C_4H_4O_6 + 2H_2O$. It is a frequent associate of tartaric acid, but is especially abundant in the grapes of the Vosges district. While in most respects it exhibits a close resemblance to tartaric acid (the two acids having the same composition, yielding, when exposed to heat, the same products, and their salts corresponding in the closest manner), it may be distinguished and separated from it by the following points of difference. It crystallizes more readily from solution; it contains two equivalents of water of crystallization; it is less soluble in alcohol; and the racemate of lime is soluble in hydrochloric acid, and is precipitated unchanged on adding ammonia. Its most important difference, however, is, that its solution does not rotate the plane of polarization, while a solution of ordinary tartaric acid exerts a well-marked right-handed rotation.

The brilliant researches of M. Pasteur on the optical and chemical properties of tartaric and racemic acids, have opened up a new and most important field of investigation in relation to the molecular composition of organic bodies. We shall give the briefest possible abstract of his remarkable discoveries, and must refer for fuller information to his numerous memoirs in the *Comptes Rendus*, *Annales de Chimie*, and other French scientific journals. He has proved that racemic acid is a mixture of ordinary tartaric acid (to which, from its optical property, he applies the term *dextro-racemic acid*) and of an acid which produces left-handed rotation, to which he gives the name *levo-racemic acid*. (These acids are also known as *dextro-tartaric* and *levo-tartaric acids*.) He found that, by saturating racemic acid with soda and ammonia, and allowing this solution to crystallize slowly, two varieties of crystals are obtained, which may be distinguished by their form, in the same way as the image and the reflection of the image in a mirror differ; or as right-handed and left-handed. If the two kinds of crystals are separated, and then dissolved, each solution is found to act powerfully on polarized light, but in opposite directions. On separating these acids from their bases, and mixing equal parts of concentrated solutions of each, racemic acid is again formed, which exerts no action on a polarized ray. M. Pasteur has subsequently made the discovery, that racemic acid may be artificially produced by the action of heat upon certain compounds of tartaric acid (such as tartrate of cinchonine or tartaric ether), which are capable of resisting a high temperature. The formation of racemic acid in this way is accompanied by the production of another modification of tartaric acid, which he calls *inactive tartaric acid*, which, like racemic acid, has no action on polarized light, but unlike it, cannot be resolved into dextro and levo-racemic acids.

Tartaric acid and the tartrates, in their relation to medicine, are of considerable importance. Pure *tartaric acid*, in small doses diluted largely with water, forms a good refrigerant drink in febrile and inflammatory affections, and is much employed for this purpose in hospitals, etc., as being cheaper than citric acid. It has been stated that persons addicted to habitual drunkenness have been reclaimed by the following treatment: A few crystals of the acid are dissolved in two small tumblers of water, and taken in the morning fasting, an hour intervening between the tumblers. The painful feeling of sinking and craving of the stomach, of which such persons usually complain, is said to be removed by these acid draughts. Under the name of *acidulated drops*, lozenges composed of this acid, sugar, and oil of lemons are largely employed in mild sore throats and colds. The principal medical use, however, of tartaric acid is in the preparation of effervescent draughts, when added to alkaline carbonates; and in the composition of seidlitz powders (q.v.). *Tartrate of potash* is a mild but efficient purgative in doses of from two to six drams, which is perhaps hardly so much used as it deserves. In passing through the system it becomes converted into carbonate, and thus renders the urine alkaline. *Acid tartrate*, or *bitartrate of potash*, commonly known as *cream of tartar*, in full doses, acts as a sharp purgative, but is generally prescribed with some of the milder vegetable cathartics. When administered in small repeated doses (from a scruple to a dram), in a large quantity of water, it largely increases the secretion of urine, and is consequently of great service in dropsy. It may be agreeably given in either of the following forms: (1) *Imperial*, which is prepared by dissolving a dram of cream of tartar in a pint of boiling water, and flavoring with lemon-peel and sugar. In incipient dropsy, a couple of tumblers of this mixture, with half a glass of good hollands

in each, are strongly recommended by Dr. Neligan as an after-dinner drink. The proportion of cream of tartar to the pint of water may be gradually increased to two drams.

(2) *Cream of tartar whey* is prepared by boiling 100 grains of the salt in a pint of new milk, and removing the curds by straining. Either of these drinks may be safely taken to any extent agreeable to the patient. *Tartrate of iron and potash*, the *ferrum tartaratum*, or *tartarated iron*, of the pharmacopœia, is a mild chalybeate tonic, which, in consequence of its somewhat sweet taste, is well adapted for children. It occurs in transparent scales of a deep garnet color, is soluble in water, and sparingly soluble in spirit. The dose varies from 5 grains to a scruple, three times a day, either given with honey or treacle, or dissolved in some aromatic water. The *wine of iron* (*vinum ferri* of the *Pharm. Brit.*) consists of sherry with tartarated iron in solution. Each dram ought to contain one grain of the salt. The *tartrate of iron and ammonia*, or *ammonio-tartrate of iron*, closely resembles in its action the tartrate of iron and potash. Although not in the *Pharm. Brit.*, it is "an excellent preparation of iron, void of all astringency. Its not disagreeable taste, its solubility in water, its compatibility with the alkaline carbonates, and the permanency of its composition, give it an advantage over most of the other preparations of iron. It is peculiarly suited as a tonic for those derangements of the uterine organs in which ferruginous salts are indicated."—Neligan's *Medicines*, 6th ed. p. 645. The dose is from 5 to 8 grains, and it may be prescribed in the form of powders, pills, or solution; or made into a bolus with honey. *Tartar emetic*, in doses of from $\frac{1}{15}$ to $\frac{1}{4}$ of a grain, frequently repeated, acts as a diaphoretic or sudorific; nausea sometimes accompanies the diaphoresis, but it has the advantage of increasing the tendency to perspiration. The addition of the compound tincture of lavender tends to prevent the supervention of vomiting. Tartar emetic in these small doses is of great service in febrile disorders, in the hæmoptysis of phthisis, in obstinate cutaneous diseases, etc. *Antimonial wine* consists of sherry holding tartar emetic in solution in the proportion of two grains to the ounce. The dose, to produce a diaphoretic action is 20 or 30 minims every hour. If we require an expectorant action—as in acute pneumonia or bronchitis—the salt should be given in still smaller doses, as from $\frac{1}{15}$ to $\frac{1}{12}$ of a grain. Tartar emetic, in doses of two or three grains, dissolved in water, acts as a powerful emetic, and at the same time produces much nausea and depression, and not unfrequently purging. The vomiting seldom occurs till about 20 minutes after the draught has been taken. If tartar emetic is thus given at the commencement of febrile or inflammatory affections, it will often cut short the impending disease. With this view it is employed in continued fever, croup, whooping-cough, etc. It used to be given to relax the muscular system, in cases of strangulated hernia and dislocation; but chloroform is far better for these objects. In cases of poisoning it is inferior to sulphate of zinc. It is expedient to take the emetic dose in parts, as too powerful an effect is thus prevented. Two grains, which are generally sufficient, must be dissolved in eight ounces of water, of which a quarter should be taken every ten minutes till vomiting ensues. The patient should walk gently about his room between the doses. If a large dose (of one, two, or even three grains) be repeated every second hour, the nausea, vomiting, and purging (which often follows a full dose) cease after two or three such doses, and the main action seems to be exerted in depressing the circulation and lowering the pulse. Hence, tartar emetic given in this way is a direct sedative or contra-stimulant, and is of great service in pneumonia and pleurisy. "As a contra-stimulant," says Neligan, "tartar emetic is given in doses of from half a grain to two grains every hour or second hour, dissolved in one or at most two ounces of orange-flower water. The first dose or two should not exceed half a grain, and the patient should not be permitted to drink, so as, if possible, to avoid the production of vomiting. When once a tolerance of the medicine is produced in the system, the quantity taken may be rapidly increased."—*Op. cit.*, p. 418. Lastly, tartar emetic, when applied to the skin, produces a crop of pustules, which ulcerate, and discharge purulent matter. In consequence of this property, tartar emetic, either in the form of ointment or of saturated solution, is often employed as a counter-irritant in various affections of the viscera of the chest and abdomen, in diseases of the joints, etc. The *ointment* is applied by rubbing about half a dram on the skin night and morning. In two or three days pustules begin to appear, when the further application of the ointment should be temporarily suspended. The saturated solution is a cleaner preparation than the ointment, and acts more speedily. It is applied by means of pledgets of lint soaked in it. Tartar emetic, in excessive doses, or in small repeated doses, acts as an irritant poison. Dr. Taylor has reported 37 cases of poisoning by this agent, of which 16 were fatal. The smallest fatal dose was in a child *three-quarters of a grain*, and in an adult *two grains*, but in the last case there were circumstances which favored the fatal action of the poison. The symptoms occurring in chronic poisoning by this salt are "great nausea, vomiting of mucus and liquids, great depression, watery purging, followed often by constipation of the bowels, small, contracted, and frequent pulse, loss of voice and muscular strength, coldness of the skin, with clammy perspiration, and death from complete exhaustion." A considerable number of cases are on record in this country in which murder has been perpetrated by the slow action of tartar emetic. The most important of them are referred to by Dr. Taylor in his *Medical Jurisprudence*, pp. 146 and 250, to which must be added the Pritchard case in Glasgow, 1865. The *Pharmaceutical Journal* for Oct., 1865, contains direc-

tions, by Messrs. T. and H. Smith, of Edinburgh, for preparing an antidote to be prescribed after a large dose of tartar emetic has been taken. The ingredients are solution of perchloride of iron and calcined magnesia.

TARTARS, or, more properly, **TATARS**, was originally a name of the Mongolic races, but came to be extended to all the tribes brought under Mongolic sway by Genghis Khan and his successors, including Tungusic and Turkic races. The term is therefore not to be considered as ethnological, though all, or almost all, the peoples included under it, in its widest sense, belong to the Turanian family, but is rather to be understood in the same sense as the term "Franks" used by Mohammedans. In the classification of languages, Tartaric has become the distinctive name of that class of Turanian languages of which the Turkish is the most prominent member, while the Mongolic form a separate class. See **TURANIAN LANGUAGES**; see *illus.*, **ETHNOLOGY**, vol. V.

TARTARUS (Gr. *Tartaros*; the name is probably onomatopœic, the reduplication being designed to express something terrible or disagreeable, like *Barbaros*, *Karkaron*, and many other words), according to Homer, is a deep and sunless abyss, as far below Hades as earth is below heaven, and closed in by iron gates. Into Tartarus, Zeus hurled those who rebelled against his authority, as e.g., Kronos and the Titans. Afterward the name was employed sometimes as synonymous with Hades or the under-world generally, but more frequently to denote the place where the wicked were punished after death—lowest hell, in fact. A noticeable feature about these punishments is their congruity with the nature of the offenses perpetrated. See **HEAVEN** and **HELL**.

TARTARY (properly **TATARY**) is the name under which, in the middle ages, was comprised the whole central belt of central Asia and eastern Europe, from the sea of Japan to the Dnieper, including Mantchuria, Mongolia, Chinese Turkestan, Independent Turkestan, the Kalmuck and Kirghis steppes, and the old khanates of Kasan, Astrakhan, and the Crimea, and even the Cossack countries; and hence arose a distinction of Tartary into European and Asiatic. But latterly the name Tartary had a much more limited signification, including only that tract bounded on the n. by Siberia, and on the s. by China and Thibet, along with Independent Turkestan; and at the present day, many writers apply it as a synonym for Turkistan (q. v.).

TARTINI, GIUSEPPE, 1692-1770; b. Pirano, Italy; received lessons in music, violin-playing, and fencing; studied law; married privately at Padua, and to avoid arrest by the bishop fled to a convent, where for two years he gave himself to the study of the violin, receiving lessons in composition from father Boemo, the organist of the convent; appointed chief violinist of the chapel of St. Anthony at Padua, 1721; established, 1728, at Padua a violin school of great celebrity. He left in MS. 48 violin sonatas, 1 trio, 127 concertos, besides his published works. *Sonate du Diable, or Tartini's Dream*, he considered his best composition.

TARTREALIC ACID and **TARTRELIC ACID**. See **TARTARIC ACID**.

TARTUFE, the name of the chief character in Molière's most celebrated comedy, which has become a synonym in all languages for a hypocritical pretender to religion. The original of the character was most probably a certain Abbé de Roquette, a parasite of the prince de Conti. The name is said to have suggested itself to Molière on the occasion of a visit to the papal nuncio, where he saw the pious and solemn countenances of the nuncio's courtiers suddenly lighted up with ecstatic animation by the appearance of a seller of truffles—in Italian, *tartuffoli*. This play excited a greater commotion than perhaps any other production of the kind ever did. It was written in 1664; but before it was brought on the public stage, partial representations of it in private companies had made its character known, and raised the alarm of the priests, who believed themselves to be specially satirized therein. Uniting with the many enemies whom Molière had already made for himself by lashing physicians, fops, and fools of all kinds, they used every means in their power to prevent the public representation of the play. The archbishop of Paris threatened with excommunication all actors who should take any part in the performance, and even those who should only read it; and one dignitary went so far as to declare that Molière—whom he called a devil in human form—was deserving of the stake. It was not till 1669 that Molière succeeded in getting the play publicly acted in presence of Louis XIV.; and then it had an uninterrupted run for three months, to the great vexation of all hypocrites.

TARUDANT, a city in the province of Sus, Morocco; about 2 m. from the Sus river, and 125 m. s.w. from Morocco; pop. about 8500. It is walled and defended by a citadel. Most of the houses have but one story, and the streets are narrow and crooked. The city is surrounded by a highly cultivated country, and itself contains many groves and gardens. Its chief manufactures are of copper, leather, and dyes.

TASCHEREAU, ELZÉAR ALEXANDRE, b. Quebec, 1820; educated at the Quebec seminary. He entered the Roman Catholic priesthood in 1842; was for some time professor of mental philosophy, and superior in the Quebec seminary, and became professor of canon law at Laval university in 1856. He became administrator of the Quebec diocese in 1870, archbishop of Quebec in 1871, and cardinal in 1886.

TASHKEND, till recently a t. of Independent Turkistan, but now in the possession of Russia, and capital of Russian Turkistan, is situated in the valley of the Tschirtehlík, in lat. 41° 20' n., long. 69° 20' e. It is the chief commercial town in the district, is the center of the transit-trade between Bokhara, Khokan, and Chinese Tartary, and has extensive trading relations with Orenburg and Petropavlovsk. Like most of the cities of central Asia, it stands in a fertile plain. It covers a large tract of ground, being said to extend 10 m. in one direction and 5 in another, and is protected by a high wall of sun-dried bricks. Within the walls are numerous gardens and vineyards, interspersed among the houses; the houses themselves are built of mud, and thatched with reeds. The streets are narrow and dirty. The chief buildings are the castle (which is fortified), various mosques, colleges, old temples, and a bazaar. The chief manufactures are gunpowder, silk and cotton goods, and iron. According to a census taken in 1887, the pop. amounted to 156,506. Tashkend is also important in a military point of view, and, mainly for this reason, had been long coveted by Russia. The Russians, who captured it in 1854, and retained it for a short time, finally took possession of it in 1865, having in the mean time made great advances in central Asia. The petition of the inhabitants, that they might be received as Russian subjects, was granted in 1866; and since then it has been governed by a kind of municipal board, the president being a Russian officer, and the members chosen by the townspeople. The trade is important, the value of foreign goods exchanged here amounting to upwards of \$20,000,000 annually.

TASMAN, ABEL JANSZON, b. Hoorn, n. Holland, about 1600; was sent, 1642, by Van Diemen, governor-general of the Dutch East India company, to explore New Holland, and on Nov. 24 discovered the island which he called Van Diemen's Land (now Tasmania). After a voyage of 10 months, in which he discovered New Zealand, the islands of the Three Kings, the Friendly, and Feejee islands, he returned to Batavia. He made a second voyage to New Guinea and New Holland, 1644. He published an account of his first voyage. He died in Batavia in 1659. His life was written by Dozy in his *Bijdragen tot de taal-, land-, en volkenkunde van Nederlandsch Indie* (1887).

TASMANIA, formerly VAN DIEMEN'S LAND, a considerable island in the South Pacific ocean, between the parallels of 40° 33' to 43° 39' s. lat., and between 144° 39' to 148° 33' e. long., lying to the s. of, and separated from, Australia by Bass's strait. Its greatest length, from cape Grim on the n.w., to cape Pillar on the s.e., is 240 m.; and its greatest breadth from e. to w., 200 m.; its area, including the adjacent islands, about 26,215 sq. miles. The capital is Hobart Town, with a pop. (1891) of 24,905, situated at the base of Mt. Wellington, on the western shore of the estuary of the river Derwent. The second chief town is Launceston, with a pop. of 17,208, situated at the head of the estuary of the Tamar, formed by the junction of the North and South Esk rivers. In the year 1854 the population consisted of—males, 30,613; females, 28,261; total, 64,874. In 1874, males, 55,117; females, 49,059; total, 104,176. Total pop. in 1893, 154,424. Hobart Town and Launceston are connected by the electric telegraph, and by an excellent macadamized road, 121 m. in length, from which good roads branch off. In 1895 there were 1789 m. of telegraph. The first line of railway, 45 m. in length, was opened in 1871, uniting Launceston with Deloraine; there are in all (1895) 475 m. of railway.

Physical Features.—The south-eastern coast of Tasmania is deeply indented by the estuaries of the Derwent and Huon, Storm bay, the inlet of Pitt Water, and Frederick Henry bay. The last is protected on the s.e. by Tasman's peninsula, reserved as a penal settlement for the colony. The chief indentations on the w. coast are Macquarie harbor (formerly a penal settlement, but now uninhabited), and Port Davey. On the e. coast are Oyster bay, between Freycinet's peninsula and the mainland; and Spring bay, sheltered on the e. by Maria island. On the n. coast, besides the estuary of the Tamar, there are numerous smaller harbors and rivers, accessible to vessels of from 30 to 300 tons. The chief of these are Circular Head, Port Sorell, and the rivers Mersey, Forth, Leven, Don, and Inglis. The scenery is of a bold mountainous character, varied by deep narrow valleys, extensive undulating tracts of country, and open plains of limited extent. Among the principal mountains are Ben Lomond (5020 ft.). Cradle Mount (5069 ft.), Ironstone Mount (4736 ft.), Mt. Barrow (4644 ft.), Mt. Wellington (4170 ft.), with many others exceeding 4,000 ft. in height. Embosomed among the central mountains, at an average height of about 3,000 ft., are numerous lakes, with a united area of about 170 sq.m., which feed the greater part of the rivers draining the s.e. slope of the island. With the exception of the reclaimed lands, the basaltic plains, and limited tracts which are unfavorable to the growth of timber trees, the whole island is more or less densely wooded. The vast forests of the western portions of the n. and s. coasts are extensively utilized for timber, and in the former, the work of reclaiming the rich heavily-timbered lands is rapidly progressing. But the major part of the western half of the island is entirely uninhabited, its soil, climate, and inaccessible position offering little inducement to the settler.

Geology and Mineralogy.—The bed-rocks of the western districts, from Bass's strait to South-west cape, consist of vast bands of slates, schists, and quartz rock, belonging to the azoic or metamorphic series. Next to these come lower paleozoic slates, with conglomerates and dark compact limestones, the latter highly charged with Silurian fossils. Unconformably upon the upturned edges of these rocks lie upper paleozoic sandstones, mudstones, limestones, and conglomerates, also traversed by dikes and masses of green-

stone and basalt, and with these, reaching an altitude of 4,000 ft. above the sea-level. In the s.e. districts, from the South Esk river on the n. to the Huon on the s.w., the lower rocks are entirely absent, or concealed beneath the upper paleozoic beds. In the n.e. district, the lower rocks again make their appearance, associated with granite and greenstone, and occasionally traversed by dikes and veins of the true auriferous quartz. Here, again, they are overlaid by upper paleozoic rocks, extensively denuded, and exposing seams of coal from 2 ft. to 14 ft. thick, at various elevations. Tertiary rocks are sparingly distributed. At the mouth of the river Inglis, on the n. coast, are beds of a whitish freestone, attaining in places a thickness of 120 ft., and containing recent shells, with extinct species of *trigonia*, *terebratula*, *cypræa*, *voluta*, etc. Tertiary lignites are found in the sandy clays of the valleys of the Derwent and Tamar, with impressions of leaves of unknown trees and plants. Over the greater part of the basin of the South Esk, comprising an area of more than 1000 sq.m., extensive deposits of clays, sands, and quartz drift are met with. No distinct traces of glacial action have been observed; but the thick beds of gravel, and the boulders, which must have traveled many miles from their parent rock, afford evidence of some powerful transporting agency, and were probably deposited in their present sites by the action of icebergs slowly drifting northward at some period prior to the last general elevation of the land.

The igneous rocks are everywhere present in great variety. The islands of the Furneaux group in Bass's strait are chiefly of granite, and form the connecting links which join the n.e. angle of Tasmania to the great dividing range of eastern Australia. Gold has been found in many places, and the workings have for years given fair returns to a limited number of miners. In 1895 the value of the gold produced was £2,960,344. Silver and antimony have been occasionally met with in the gold drifts, and very rich deposits of tin have begun to be worked at Mount Bischoff. In 1892, £256,083 worth of tin ore was produced. Copper occurs in thin veins, associated with galena, on the n. coast, near the river Leven, and galena has been found elsewhere in the primitive limestones. Red and brown hematites, containing a large percentage of iron, occur at various points on the n. coast, in large masses and lodes. Iron-works on an extended scale are now in operation. Coal is worked in several parts of the island, chiefly for local consumption. A large lode of bismuth was discovered in 1875. The older limestones yield fine varieties of marble, and excellent building stone is obtained from the greenstones, basalts, and paleozoic sandstones. Silver to the value of £158,859 was exported in 1893. Valuable deposits of zircons, allied with other gems and rare earths, have been discovered on the n.w. coast.

Botany.—The flora of Tasmania has been fully described in the botany of the antarctic voyages by Hooker and others. The majority of the species are common to Australia and Tasmania. Of those which are peculiar to the latter, many are limited to particular localities. The most widely diffused genera are the eucalypti and acaciæ, the former yielding the ordinary timber of the colony. The blue gum (*eucalyptus globulus*) reaches a height of 350 ft., with a corresponding girth. The blackwood (*acacia melanoxylon*) and the huon pine (*dacrydium franklinii*) also yield valuable timber, which, together with the hardwoods from the eucalypti, is largely exported to the neighboring colonies. A species of beech *fagus Cunninghamii*, locally known as the myrtle, and growing in great abundance in some parts of the island, also produces a highly valuable timber, which has not yet received the attention which it merits. There are many beautiful shrubs and plants, but the flowers are usually small and inconspicuous. All the common fruit-trees and culinary vegetables of England have been introduced, and grow with great luxuriance and vigor. Oranges and lemons are cultivated in some situations, but do not usually ripen their fruit. The introduction and cultivation of exotic trees and plants is energetically carried on in the botanical gardens under the direction of the Royal Society.

Zoology.—Of the 30 species of mammals, one-half belong to the sub-class *aplacentalia*, comprising the *marsupialia* (kangaroo, wallaby, opossum, wombat, etc.), and two species of the singular order *monotremata* (ornithorhynchus and echidna). Among the marsupial animals peculiar to Tasmania, the chief are the thylacine (*thylacinus cynocephalus*) and the Tasmanian devil (*dasyurus ursinus*), both of which are sometimes very destructive to sheep in the outlying districts. The skin of the kangaroo is much prized for leather, and there is always a market for opossum fur. Whales and seals, formerly very abundant on the coasts, are now rare; but whaling is still extensively carried on in the adjacent seas. The birds of Tasmania have been admirably described by Gould. The majority are identical with Australian species. The emu is extinct, and black swans are seldom seen in the settled districts. There is abundance of native game, which is now protected by act of parliament during the breeding season. A species of puffin (*Puffinus brevicaudus*), locally known as the mutton-bird, frequents some of the islands in Bass's strait in countless numbers, and many thousands are annually slaughtered for the sake of their oil, and for food by the half-caste islanders. Fish are plentiful in the seas and rivers, the best being known by the local name of trumpeter, and reaching a weight of 40 lbs. There are 13 species of snakes, most of which are venomous, but accidents from their bite are of very rare occurrence. Many species of insects and crustaceans have been described by Erichson, Gray, Gunther, and others. A comprehensive and accurate account of the *fauna* of Tasmania is still however, a desideratum.

Fallow-deer, and several of the English game-birds, have long been naturalized, and salmon have been introduced after several unsuccessful attempts.

Climate, Soil, Produce, etc.—The climate of Tasmania is fine and salubrious. From observations taken at Hobart Town, and extending over a period of twenty years, the extreme of heat appears to be 105° , and of cold $29^{\circ} 8'$. The mean temperature of the hottest month (January) is $63^{\circ} 57'$, and of the coldest (July), $45^{\circ} 82'$, and of the whole year, $54^{\circ} 92'$. In some parts of the island, the temperature, even in winter, rarely sinks to 45° . Snow seldom falls in the settled districts, and does not lie on the ground except on the high table-lands of the interior. The average annual rain-fall at Hobart Town is 23 inches, and the average for the rest of the island about 35 in., except in the western country and the high lands, where a fall of 75 in. has been registered in the year.

The agricultural lands may be divided into three classes—alluvial deposits, tertiary clays, and loamy soils, derived from the decomposition of different kinds of basalt. In their virgin state, some are marvelously productive. On new land, 100 bushels of oats, 70 bushels of wheat, and 15 tons of potatoes per acre, are not uncommon crops. The fertility of the soil has encouraged a system of slovenly farming. In many instances, the land has been cropped with wheat and oats for upward of thirty years without any application of manure, or any rest save an occasional summer fallow. The export trade in the staple articles of produce has much fallen off of late years, partly because the neighboring colonies have begun to depend more upon their own resources, but partly also through the deterioration of the soil from improvident management, and the necessarily increased cost of production. There are skilled and careful farmers in every district, but they are exceptions to the rule. The open pastoral lands are admirably adapted for sheep. The wool from some of the larger establishments is much valued, and brings the highest price in the London market. The cattle and agricultural horses of some of the northern districts are unsurpassed in the colonies. Pastoral and agricultural associations have been formed to promote improvements in the system of farming, and to encourage the breeding and importation of pure stock. The total area of the colony is 16,778,000 acres, of which 10,860,426 is unalienated land. In 1895 there were 212,703 acres under crop. In 1896 the number of horses in the colony was 31,580, of cattle 162,801, and of sheep 1,523,846. In 1895 the exports amounted to £1,373,063, the chief staple article being wool; the imports were £1,094,457. In 1896 the yield of wheat was 1,164,855 bushels; oats, 906,934 bushels; potatoes, 81,243 tons; hay, 62,345 tons.

Administration.—Since the passing of the "constitutional act" in 1854, the governing authority has been vested in a parliament, consisting of the governor as the queen's representative, and two elective houses, the legislative council of 18, and the assembly of 37 members. The qualification of voters is, for the former, a freehold of any value of £20, or a leasehold of £80, and for the latter to possess property or have an income of £60 per annum. Graduates of British universities, and all holding a commission in the army or navy, or in holy orders, are entitled, *ex officio*, to vote at the election of members of both houses. The public debt of Tasmania on Dec. 31, 1895, amounted to £8,180,925 and consisted chiefly of 4% debentures. The greater part of the revenue, namely about 60%, was derived from the taxes, chiefly from the heavy customs duties, amounting in 1895 to about 28% of the value of the imports. The next in importance is the revenue from railways, posts, telegraphs and other public services; the rest comes chiefly from the crown lands. The chief item of expenditure was the interest on the public debt, which amounted to 43% of the total expenditure. The next item in importance was special public works, amounting to 31% of the total expenditure. The revenue for the year 1895 was £761,971. The expenditure for the year 1895 was £748,946. The upset price of land is £1 per acre, payable by installments extending over eight years; but lots which remain unsold after being offered for sale by public auction may be purchased, under certain restrictions, at greatly reduced rates. In the unsettled districts, large tracts of land are obtainable at nominal prices. In 1862 an act, known as "Torrens's real property act," was passed to facilitate the transfer and conveyance of land. Property which had been brought under the operation of this act can be conveyed, without reference to value, upon payment of 16s. registration-fee, £1 for new certificate of title, and 2s. for forms. Mortgages can be effected on equally moderate terms.

Religion and Education.—Until a recent period, £15,000 was annually reserved for the support of religion, and this sum was divided among the various religious denominations according to their respective numbers at the census. By a return in 1891 there were: Church of England, 76,082; Roman Catholics, 25,805; Presbyterians, 9756; Wesleyans, 17,150; Independents, 4501; Baptists, 3285; Jews, 84. The state grants are largely supplemented by endowments and by local contributions. In 1895 the government paid £35,501 to the cause of education. The system is based upon the principles established by the Irish national board. The teachers are appointed by the board, and are under the supervision of the inspector of schools. In 1854, the total number of schools was 50, at which the average attendance of pupils was 2624. In the beginning of 1895 there were upward of 260 schools supported by the government, and 19,907 children on the rolls. Education in Tasmania is compulsory. In 1891, 37,034 persons (or 25.4%) of the population could neither read nor write.

For the promotion of higher education, provision is also made by the legislature. Two scholarships, each of the value of £200 a year, and tenable for four years at either of the English universities, are annually open to competition under the direction of the

council of education, and exhibitions to the higher schools, with other local honors, are periodically awarded by the same body.

Aborigines.—The number of the aborigines at the first colonization of Tasmania has been variously estimated, but probably at no time exceeded 3,000. There were several tribes occupying distinct parts of the island, and differing from each other in dialect and customs; but of a generally uniform type more nearly allied to the Negritos of New Guinea than to the aborigines of Australia. The average height of the men was from 4½ to 5½ ft.; of the women, considerably less. Color, a bluish black; the facial angle 75° to 80°; eyes, dark brown, with jet-black pupils; hair, sometimes lank, but generally crisp or woolly; forehead, high and narrow; limbs, lean and muscular; feet, flat and turned inward. Polygamy appears to have been tolerated: the women performed all menial duties, and were specially charged with that of carrying fire from place to place, when the temporary encampment was broken up. Their usual shelter was a "break-wind," constructed of boughs, but traces of rude huts have been observed. In summer, they went entirely naked, at other times wearing coverings made from the skins of the kangaroo and opossum, which formed their chief food. The coast tribes, at certain times of the year, lived almost exclusively on shell-fish, and the remains of their feasts have often been mistaken for recent marine deposits. Among other articles of food were the roots of the esculent fern, the heart of the tree-fern, and grass-tree (*xanthorrhæa*), the seeds of the boobialla (*acacia sophora*), and a singular fungus (*myliitta Australis*), commonly known as "native bread," which grows under ground near the roots of decayed trees. No traces of cannibalism were observed. Their only weapons were the spear and waddy, a wooden club about 2 ft. 4 in. in length. The early relations between the settlers and aborigines were friendly; but as the latter were gradually dispossessed of their favorite hunting grounds, they became inveterately hostile. Shot down without mercy by the settlers, they revenged themselves by bloody reprisals, and for many years the unequal struggle continued, until their numbers were reduced to a few hundreds. In 1830, an attempt was made to drive the whole body into Tasman's peninsula, by means of a cordon extending across the whole island, and gradually closing in toward the s.e.; but it failed ridiculously, as might have been foreseen. In the following year, Robinson, a builder of Hobart Town, undertook to conciliate the surviving remnants of the various tribes, with a view to their removal to Flinders island, and this he successfully accomplished, after four or five years of patient, self-denying labor. In spite of all the care bestowed upon these unfortunate people their numbers rapidly decreased, and only 45 remained when the settlement was removed, in 1847, to a more convenient station at Oyster cove, near Hobart Town. There were in 1865 only six remaining. No children had been born among them for many years, and the race is now wholly extinct, the last of the number having died a few years ago.

History.—The island was first discovered by Tasman on Nov. 24, 1642, and named by him Van Diemen's Land, in honor of his patron, the then governor of the Dutch possessions in the East Indies. During the next century, no visit is recorded; but between 1772 and 1802, partial surveys and explorations were made by English and French navigators. In 1803, Lieut. Bowen was dispatched from Sydney with a few soldiers and convicts to form a settlement in the s. of Tasmania, which was finally fixed on the spot where Hobart Town now stands. In 1804, a settlement was formed near the mouth of the Tamar, which was removed in 1806 to the spot now occupied by the town of Launceston. From 1817, commenced a rapid increase in the number of free settlers, who received grants of land in proportion to the capital which they brought into the colony, and were subsequently further aided in the clearing and cultivation of their estates by the assignment of convicts as their servants. In 1825, Tasmania was declared independent of New South Wales.

The colony was for a good many years agitated by the question of the disposal and management of the convicts, who were now becoming a prominent and formidable element in the community. At last, in 1853, transportation to Tasmania and New South Wales was finally abandoned by the home government. The abolition of transportation, and the consequent cessation of a vast imperial expenditure, naturally produced a considerable depression in all branches of trade, especially in the southern districts. It is not surprising that the great body of the colonists, instead of setting themselves manfully to turn the true and natural resources of the country to the best account, have rather looked for some great discovery of rich gold-fields, or some gigantic works undertaken under the auspices of government, as the only means by which the prosperity of the colony was to be assured. But such a state of things must ultimately work its own cure. Viewed in a true light, the progress, social, material, and political, has presented a more hopeful aspect since the extinction of the convict system than at any earlier period. For years after the discovery of gold in Australia, the *expirees* of Tasmania flocked in crowds to the neighboring colonies, attracted by the prospect of richer gains, and glad to escape from police surveillance in a country where their antecedents were too well known. Those who remained had, for the most part, by this time become orderly, well-conducted members of the community, not to be distinguished from the immigrant population by whom they were surrounded. Necessity will in due time develop the enterprise and energy which have too long lain dormant. Some of the older settlements may prove inadequate to the maintenance of their former

population, but the rich lands of the n. coast offer to industrious settlers a field which is practically inexhaustible. For type of people, see illus., AUSTRALIA AND TASMANIA, vol. II.

TASMAN NIA, a genus of shrubs of the natural order *magnoliaceæ*. *T. aromatica* is an evergreen bush of Van Dieman's land, growing in the richest soils on the margins of rivers and in shady ravines, and sometimes forming thickets of large extent. Every part of the plant is highly aromatic and pungent. The fruit is occasionally used as pepper.

TASSAERT, NICOLAS FRANÇOIS OCTAVE, 1800-74; b. France; studied art at the Paris school of art and under eminent masters of painting. His first picture was exhibited in 1831. His field was wide, including historical and *genre* pieces as well as portrait-painting. Among his best productions are "Le Marchand d'Esclaves;" "Le Sommeil de l'Enfant Jésus;" and "Funérailles de Dagobert à Saint Denis."

TASSIN, A. G., b. France, 1843; educated at the St. Cyr military school of France; was appointed 1st lieu. 35th Ind. vols., 1861; capt., 1863; maj., 1864; col., 1865; brevetted brig.gen. and maj.gen. for gallantry. He resigned to accept commission in the French army during the Franco-Prussian war; was made knight of the legion of honor. He was afterward reappointed by Pres. Grant, as colonel in the U. S. army. He was author of *Northern California Indians*; *The Indian Tribes of the Pacific Coast*; *The Flora of Arizona*; and translations of military works.

TASSISUDON, the summer capital of Bhotan (q. v.), stands on the right bank of the Godadda, an affluent of the Brahmaputra, 15 m. w. of Punakha. Many of the inhabitants, the number of whom has not been ascertained, are employed in manufacturing paper, and in making brass images and ornaments for their places of worship.

TASSO, BERNARDO, an Italian poet of considerable distinction, but most famous as the father of the illustrious Torquato, was b. at Bergamo, Nov. 11, 1493. Both by his father's and mother's side he was connected with the ancient family of the Tassi, known in the 13th c. for having organized and superintended the postal service in Italy, Spain, and Germany. His uncle, Luigi Alessandro, bishop of Recanati, took charge of his education, and under his care he turned out a fine classical scholar, his love of poetry at the same time becoming every year more ardent. The assassination of the cardinal in 1520, deprived him at once of protection and support, and for several years he wandered about Italy in a rather necessitous condition. Like his son, he was exceedingly fond of the patronage of noble lords and the smiles of noble ladies. After 1525 we find him high in favor with persons of influence. Guido Rangone, general of the papal forces, intrusted him with several missions, among others to the prince of Salerno, who appointed him his secretary; and Tasso accompanied the prince on the expedition against Tunis in 1534. In 1536 he married, at Salerno, a young lady of Sorrento, Porzia de' Rossi, who added genuine merit to the advantages of birth, beauty, and fortune, and by whom he became the father of Torquato. The fall of the prince of Salerno (who had incurred the enmity of Charles V.) brought with it the ruin of Tasso's worldly prosperity, and he was obliged to seek for a new patron. He was not long in finding friends. Guidubaldo, duke of Urbino, and Guglielmo, duke of Mantua, strove for the honor of attaching the poet to their court. The latter succeeded, and named him governor of the city of Ostiglia, where he died Sept. 4, 1569.

Tasso's principal writings, chronologically arranged, are: *Rime* (Ven. 1531); *I tre Libri degli Amori* (Ven. 1537); *Ode e Salmi* (Ven. 1560); *L'Amadigi*, *Poema* (Ven. 1560); and *Il Floridante*, *Poema* (Mant. 1587). Of these the principal is *L'Amadigi* (Amadis), which some Italian critics have not hesitated to place above the poem of Ariosto; but without adopting this extravagant estimate, we may justly admire it for the sweetness and elegance of its language, and for the beauty of its descriptions and comparisons.—For a good idea of the politics and literature of the time, see Seghezzi's edition of his *Letters* (3 vols., Padua, 1733-51), to which there is prefixed a biographical notice.

TASSO, TORQUATO, one of the greatest poets of Italy, was the son of the preceding, and was born at Sorrento in Naples, Mar. 11, 1544. His earliest education was received from the Jesuits. During his childhood, Tasso's father was an exile, but the affectionate solicitude of his mother well supplied the want of paternal care. In 1554 he went to Rome to join his father, and left his mother (whom he was destined never again to see) in a convent at Naples. At Rome, and subsequently at Bergamo, Urbino, Pesaro, and Venice, he continued to prosecute his studies. He assisted his father in copying, correcting, and even in completing his poem *L'Amadigi*, though as yet only 16 years of age. No wonder old Bernardo was delighted at the promise shown by his son, and prophesied in his letters that Torquato would yet become a great man. Later, however, sad experience of the miseries of a poet's life induced him to send Tasso to Padua, to study jurisprudence under the celebrated Panciroli. But whom the gods have made poetical can never sink into a lawyer. The youth remained at Padua a year, and wrote *Rinaldo* (Venice, 1562), a poem in 12 cantos, the hero of which is the son of Aymon, and cousin of Roland. It belongs, therefore, to the class of heroic romances. After the first burst of anger was over, Bernardo forgave his son for following his example rather than his precept, and became prouder of Tasso's genius than ever. Tasso now betook himself to the university of Bologna, to study philosophy, and is said to have distinguished himself

by an extraordinary facility in the discussion of the most elevated and abstract themes—a circumstance that perhaps says more for his power of rhetoric than his power of speculation. On leaving Bologna, he spent some time with friends at Castelvetro, Modena, and Corregio, but returned to Padua at the request of his friend Scipio de Gonzaga, afterward cardinal, who had established a literary academy there, of which Tasso became a member. It was during this second residence at Padua that he conceived the first idea of his great work, the *Gerusalemme Liberata*, a heroic record of the conquest of Jerusalem by the crusaders under the command of Godfrey de Bouillon. Lamartine beautifully describes the mingled motives of the poet: “Urged by piety no less than by the muse, Tasso dreamed of a crusade of poetic genius, aspiring to equal by the glory and the sanctity of his songs, the crusaders of the lance he was about to celebrate.” The same critic goes on to observe, in allusion to the less noble passion for the applause of courts that marked the poet: “The names of all the noble and sovereign families of the west would be revived in this epic catalogue of their exploits, and would attract to the author the recognition and favor of the great. . . . Finally, the poet was himself a knight, noble blood flowed in his veins, to celebrate warlike deeds seemed, as it were, to be associating his name with those of the heroes who had performed them on the field of battle: thus religion, chivalry, poetry, the glory of heaven and earth, the hope of eternal fame, all combined to urge him to the undertaking.” Bernardo heard of his son’s design with exulting joy, and blessed heaven for making Torquato a greater genius than himself. Meanwhile (1565), Tasso had been introduced by cardinal Luigi d’Este (to whom he had dedicated the *Rinaldo*) to his brother, Alfonso II., sovereign duke of Ferrara. Here for a time he was supremely happy. Young, handsome, courteous, and with that proper tinge of melancholy in his disposition that possesses an irresistible charm for women, he soon became a universal favorite with the beauties of the court. While their bright eyes rained influence, Tasso painted his *Armida* and *Herminia* almost without effort. It is only just to add that the attempt to seek the origin of his subsequent miseries and madness in a presumptuous passion for Leonora, sister of the duke of Este, which was first encouraged, then repulsed, and finally punished with imprisonment, is utterly at variance with the notorious facts of the case. Space does not permit us to examine the question here, but it appears necessary to correct errors of traditions so specious as to have imposed upon illustrious men. Tasso courted, platonically and otherwise, various ladies of the court—a pretty chambermaid even was not beneath his notice; but there is not a vestige of evidence to show that he lifted his eyes to the sister of his sovereign, or that such a suspicion was ever harbored by the lady herself or her brother. In truth, his madness was connected in its origin more closely with his poetry than with his loves. Having finished his great epic about 1575, he sent a copy of it to a society of scholars, critics, and churchmen at Rome, to get their opinion of it. It would have been far better had he published the poem at once, without placing it at the mercy of critics who were delighted to have the opportunity of finding fault before the public was in a position to praise. The critics would then have been forced to swell the chorus of general admiration. Tasso was tortured by their waspish comments, and, with pitiable agonies, proceeded to make his work more agreeable to his incapable judges. Gradually a morbid melancholy overpowered his reason; the spites and jealousies that are never absent from a gay and pleasure-loving court contributed to increase his mental disorder. He believed that invisible persecutors had denounced him to the inquisition as a heretic. It was in vain that Alfonso and his sisters tried to calm the perturbations of his spirit, and even got the inquisition to write him a reassuring epistle. His paroxysms increased in violence. Finally one evening (June 17, 1577), he drew his dagger in the apartments of the duchess of Urbino, to stab a domestic whom he conceived to be one of his secret enemies; whereupon Alfonso had him confined in his palace and at Belignardo for his health’s sake, rather than to punish him. On July 20 he made his escape, and fled across the Abruzzi to his birthplace, Sorrento, where he took refuge with his sister. The air of his native place quickly restored him to health; but no sooner had he recovered than he began to yearn for the old excitements, begged Alfonso to take him back, and when that prince drily informed him that he might return if he pleased, Tasso greedily availed himself of the cold permission, and was soon as wretched as before. A new flight ensued, this time toward the north of Italy. The unhappy poet wandered at last half-naked into the city of Turin, where he was humanely received by the marquis d’Este, brother of Alfonso. After some time, he again ventured to return to Ferrara, Feb. 21, 1579, but only to madden, almost as soon as he breathed its noxious air. Alfonso was again obliged to put him under constraint, in which he remained upward of seven years, when the duke, at the request of several of his brother sovereigns, released him (July 5, 1586). During the remainder of his life Tasso lived chiefly at Naples. Almost the last incident of his career was his visit to Rome to receive (like Petrarch) the honor of a public coronation on the Capitol. The excitement was too much for his ruined frame. A slow fever seized him; he was removed to the convent of Santo Onotrio, on the Janiculum, and there, before the laurel could be conferred, died, April 25, 1595, after a brief illness. It should be noted that in 1570, T. visited France, where he spent a year, gaining the friendship of Charles IX. See Black, *Life of T.* (Edinb. 1810); Ebert, *T. Tasso’s Leben* (Leip. 1819); Zuccala, *Della Vita di Tasso* (Mil. 1819); Milman, *Life of T. Tasso* (Lond. 1850); Cibrario, *Degli Amori e Della Prigione di Tasso* (Tur. 1862).

Besides his *Gerusalemme Liberata*, Tasso wrote a great number of works in verse and prose, among which may be mentioned *Rime, insieme con altri Componimenti* (Ven. 1581); *Dialoghi e Discorsi* (Ven. 1586-87); *Lettere Familiari* (Bergamo, 1588); *Rime* (Brescia, 1592-93); and *Gerusalemme Conquistata* (Rome, 1593). The most complete edition of his works appeared at Pisa (1821-32), in 33 vols. See Hasell's T. (1882).

TASTE, ORGAN AND SENSE OF. The principal seat of the sense of taste is the mucous membrane of the tongue, in which dissection reveals a *cutis* or *chorion*, a *papillary structure*, and an *epithelium*. Of the *cutis*, it is sufficient to remark that it is tough, but thinner and less dense than in most parts of the cutaneous surface, and that it receives the insertions of the intrinsic muscles of the tongue, which will be described when we treat of that organ generally. The *papillary structure* differs from that of the skin in not being concealed under the epithelium, but in projecting from the surface like the villi of the digestive canal, and it thus gives to the tongue its well-known roughness. The *epithelium* (q. v.) is of the scaly variety, as on the skin, but is much thinner on the tongue than on the skin. It is most dense about the middle of the upper surface of the tongue, and it is here that, in disordered digestion, there is the chief accumulation of *fur*, which in reality is simply a depraved and over-abundant formation of epithelium. The *papillæ* on the surface of the tongue are either *simple* or *compound*. The former, which closely resemble those of the skin, are scattered over the whole surface of the tongue in parts where the others do not exist, and they likewise participate in the formation of the compound papillæ, which, from their forms, are respectively termed (1) the *circumvallate* or *calyciform*, (2) the *fungiform*, and (3) the *conical* or *filiform*.

The *circumvallate* papillæ are not more than eight or ten in number, and are situated in the form of a V at the base of the tongue. Their function seems to be to secrete mucus, as well as to take part in the act of tasting. They consist of "a central flattened projection of the mucous membrane of a circular figure, and from $\frac{3}{10}$ to $\frac{1}{12}$ of an inch wide, surrounded by a tumid ring of about the same elevation."—Todd and Bowman, *Physiological Anatomy and Physiology of Man*, 2d ed. vol. i. p. 437. The *fungiform* papillæ are scattered over the surface in front of the circumvallate papillæ, and about the sides and apex. They are usually narrower at the base than at the apex, where they are about $\frac{1}{30}$ of an inch in diameter. They are covered with simple or secondary papillæ, and their investing epithelium is so thin that the blood circulating in them gives them a red color, which is not seen in the conical papillæ, among which they are distributed. They contain nerves terminating in loops. The shape of the *conical* or *filiform* papillæ is indicated by their names; and even if they take little part in the sense of taste directly, it is convenient to describe them here. Their average length is about $\frac{1}{10}$ of an inch. The papillæ terminate in long pointed processes, which are bathed by the mucus of the mouth, and are capable of moving in any direction, although they are generally inclined backward. Some of the stiffer of these epithelial processes inclose minute hairs. Messrs. Todd and Bowman surmise, on structural grounds, that the filiform papillæ "can scarcely share in the reception of impressions which depend on the contact of the sapid material with the papillary tissue. The comparative thickness of their protective covering, the stiffness and brush-like arrangement of their filamentary productions, their greater development in that portion of the dorsum of the tongue which is chiefly employed in the movements of mastication, all evince the subservience of these papillæ to the latter function rather than to that of taste; and it is evident that their isolation and partial mobility on one another must render the delicate touch with which they are endowed more available in directing the muscular actions of the organs. The almost manual dexterity of the tongue in dealing with minute particles of food is probably provided for, as far as sensibility conduces to it, in the structure and arrangement of these papillæ."—*Phys. Anat. and Phys. of Man*, vol. i. p. 441. Notwithstanding the difference in their outward form and mode of arrangement, the simple papillæ, which have been detected by Todd and Bowman as scattered over the whole dorsum of the tongue (although concealed under the common sheet of epithelium), and those clothing the circumvallate and fungiform papillæ, do not seem to present any structural difference; and their epithelium, which is very thin, readily permits the transudation of sapid substances dissolved in the mucus of the mouth. With regard to the use of the singular configuration of the circumvallate and fungiform papillæ, "it may be conjectured that the fissures and recesses about their bases are designed to arrest on their passage small portions of the fluids in which the sapid materials are dissolved, and thus to detain them in contact with the most sensitive parts of the gustatory membrane."—*Op. cit.* p. 441.

There has been much discussion regarding the precise seat of the sense of taste and the true nerves of taste. Although the surface of the tongue is the special seat of gustative sensibility in man, the sense of taste is by no means restricted to that organ, being diffused, in a less degree, over the soft palate, the arches of the palate, and the fauces. Moreover, the gustative sensibility varies on different parts of the surface of the tongue. It is generally allowed that acute taste "resides at the base of the tongue, over a region of which the circumvallate papillæ may be taken as the center, and also on the sides near the base. These parts are supplied solely by the glossal twigs of the glosso-pharyngeal nerves. Some writers, among whom are Valentine and Wagner, believe the mid-

dle and anterior parts of the dorsum of the tongue to be usually incapable of appreciating flavor; while numerous others hold the contrary opinion, with which our own careful and repeated experiments, on other persons as well as ourselves, quite accord. Sour, sweet, and bitter substances applied to the sides, and especially to the tip of the protruded tongue, we find to be at once distinguished; though, when placed on the middle of the dorsal region, they make little or no impression till pressed against the roof of the mouth. This region of the tongue is supplied almost solely by the lingual branch of the fifth nerve. We conclude generally, with regard to the tongue, that the whole dorsal surface possesses taste, but especially the circumferential parts, viz., the base, sides, and apex."—*Op. cit.*, pp. 442, 443. The investigations of Messrs. Todd and Bowman further show that the soft palate and its arches are endowed with taste in some persons, but not universally, while they got no evidence in any case of gustative sensibility on the pharynx, gums, or elsewhere. The soft palate and its arches are supplied by palatine branches from Meckel's ganglion, and sparingly by the glosso-pharyngeal nerves. From (1) the evidence afforded by the anatomical distribution of the nerves to parts enjoying the sense of taste, (2) the evidence of experiments, in which the various nerves of the tongue were divided, and (3) the evidence afforded by disease, it may be safely inferred that the glosso-pharyngeal and the lingual branches of the fifth pair of nerves respectively participate in the sense of taste; and there is also reason to attribute a share to the palatine branches of the fifth.

Impressions of taste may be produced by a mechanical or chemical excitement of the gustatory nerves. A quick light tap of the finger on the tip of the tongue causes a taste, sometimes acid, sometimes saline, which lasts for several seconds; and galvanism acts similarly. If the surface of the tongue, near the root, be touched with a clean dry glass rod, or a drop of distilled water be placed upon it, a slightly bitterish sensation is produced; and if the pressure be continued, a feeling of nausea ensues. If a small current of cold air be directed against the tongue, it excites a cool saline taste like that of saltpeter. From the experiments of E. H. Weber, it appears that one of the conditions requisite for the due exercise of the sense of taste is a temperature not departing far on either side from the natural standard. Thus, if the tongue be immersed for a minute in water at a temperature of 125°, or in iced water, the taste of sugar, etc., is no longer perceived. In order that sapid bodies should cause taste, it is necessary that they should be dissolved, and made to permeate the tissue of the papillæ, so as to come in contact with their nerves. This is proved by the two following facts: 1, that every substance, whether solid, fluid, or gaseous, which possesses a distinct taste, is more or less soluble in the fluids of the mouth, while substances which are perfectly insoluble are only recognized by the sense of touch; and 2, that if the most sapid substance be applied in a dry state to a dried part of the surface of the tongue, no sensation of taste is excited. Bitters and acids appear to be the most sapid bodies, since they may be diluted to a greater extent than any other known substances without ceasing to excite sensations of taste. Thus, according to Valentin, 1 part of extract of aloes, or of sulphuric acid, in 900,000 of water, and even 1 part of sulphate of quinia in 1,000,000 parts of water, may, with ease, be distinguished from perfectly pure water. "The contact of a sapid substance," says Dr. Carpenter, "much more readily excites a gustative sensation when it is made to press upon the papillæ, or is moved over them. Thus there are some substances whose taste is not perceived when they are simply applied to the central part of the dorsum of the tongue, but of whose presence we are at once cognizant by pressing the tongue against the roof of the mouth. The full flavor of a sapid substance, again, is more readily perceived when it is rubbed on any part of the tongue, than when it is simply brought in contact with it, or pressed against it. Even when liquids are received into the mouth, their taste is most completely discriminated by causing them to move over the gustative surface: thus, the "wine-taster" takes a small quantity of the liquor in his mouth, carries it rapidly over every part of its lining membrane, and then ejects it."—*Principles of Human Physiology*, 6th ed. p. 621. Most sapid substances affect the nerves of smell to a greater or less degree, as they pass down the throat; and it is this compound of taste and smell that constitutes *flavor*. It is a common habit to hold a child's nose when he is taking a nauseous draught, with the view, as is supposed, of deadening the taste. The efficacy of the process depends upon the exclusion of smell, and the reduction of the flavor of the medicine to its mere taste. The agreeable sensation produced by sipping good wine is due to what is termed its *bouquet*, or in other words, to its flavor, or combined taste and smell. Some substances leave a taste in the mouth very different from that which they first produced. This *after-taste* is usually bitter; but in the case of one of the most bitter substances known, namely, tannin, it is sweet. This connection seems, in a degree, to correspond to the complementary colors in vision.

There can be no doubt that the sense of taste has for its primary object to direct us in the choice of food, to make the act of eating agreeable, and to excite the flow of mucus and saliva which aid the digestive process; and among the lower animals, the instinctive perceptions connected with this taste are much more remarkable than in man. As a general rule, it is found that those substances whose taste is agreeable are useful articles of food, and *vice versâ*; although there are some well-known exceptional cases.

Sir Henry Holland, in his *Medical Notes and Reflections*, observes that in the majority of instances of actual illness, the desires of the patient as to food and drink may be safely complied with, even when some seeming extravagance of diet is suggested; and that in the early stage of recovery from gastric fevers he has seen many curious instances of such contrariety to all rule acquiesced in with manifest good to the patient. "Dietetics," he adds, "must become a much more exact branch of knowledge, before we can be justified in opposing its maxims to the natural and repeated suggestions of the stomach, in the state either of health or disease."

TATE, a co. in n.w. Mississippi; watered by Coldwater river, traversed by the Illinois Central railroad; about 390 sq. m.; pop. '90, 19,253, includ. colored. The surface is mostly level. The soil is fertile. The principal productions are corn, wheat, cotton, and potatoes. Co. seat, Senatobia.

TATE, NAHUM, a poet and dramatist, son of the Rev. Dr. Faithful Tate, was b. in Dublin in 1652, and educated at Trinity college, Dublin. In 1692, he succeeded Shadwell as poet-laureate, and held that dignity till his death in 1715. His habits were somewhat improvident, and in the latter part of his life resided within the precincts of the mint at Southwark, then a privileged sanctuary for debtors—hence perhaps that "downcast look" and inability to "say much for himself," for which, it is said, he was remarkable. His writings include nine or ten dramatic pieces, *Panacea*, or *a Poem on Tea*, various birthday odes, and an elegy on the death of Queen Mary. He lived to write the first birthday ode for George I. But Tate is best known by the metrical version of the Psalms, which he executed in conjunction with Dr. Nicholas Brady, chaplain to king William and queen Mary, which was attached to the prayer-book, and came into general use in the church of England, supplanting the older version made in the reign of Edward VI. by Sternhold and Hopkins.

TATHAM, WILLIAM, 1752-1819; b. England; emigrated to America in 1769 and engaged in business in Virginia. He served in the revolutionary war, was admitted to the bar in 1784, and two years later settled in Lumbarton, N. C., which he represented in the legislature in 1787. He was superintendent of the London docks, 1801-5, after which time he returned to this country. In 1817 he became a United States military storekeeper. Having lost his property he committed suicide on Washington's birthday by throwing himself before a cannon.

TATIAN, one of the early apologists of Christianity against the pagan philosophers, and the founder of a sect which, whether under his own name, or under various other appellations derived from its peculiar tenets or practices, attracted considerable notice in the primitive ages. Tatian was b. in Syria or Assyria about the year 110. Having cultivated rhetoric and philosophy in various places, he came to Rome about 162, where he became the disciple and friend of Justin the martyr, and was by him converted to Christianity. He is known to have written many works—*infinita volumina*, says Jerome—of which, however, only one is preserved, the Apology already referred to. The date of its composition is uncertain, but it seems probable that it was written before the death of Justin (166 A.D.). No trace appears in the Apology of the heterodox opinions of Tatian, and it is alleged by Tertullian (*Adv. Hær.* i. 28, 1) that it was not till after the death of Justin that he fell into the errors to which he has given a name. He then removed to the East, and is said to have established himself in Mesopotamia. Without entering into the details of Tatian's peculiar opinions, it will be enough to say that, especially in their moral aspect, they formed the foundation of one of the great divisions of Gnosticism. Starting from the common principle of dualism, and of the origin of matter from the evil principle, and its consequent evil nature, Tatian, unlike the Egyptian Gnostics, held the necessity of overcoming the corrupt nature of man, and purifying it by abstinence and ascetic rigor. Accordingly, he reprobated marriage, and condemned all sensual indulgence. One of his "opinions," affirming the damnation of Adam, was peculiarly odious to the orthodox party. He condemned the use of wine so strongly as to forbid it even in the celebration of the Eucharist, in which his followers permitted only water to be used, whence they received the name of *Hydroparastatai* (from *hydor*, water, and *paristemi*, I present), and in Latin *Aquarii*. From their generally rigorous asceticism, they were called *Encratites* (from *engkratein*, to keep continent). In their dogmatic views as to Docetism, the Demiurge, and Emanations, they differed little from other Gnostics of the Syrian school. See GNOSTICS, MANICHÆANS, MYSTICISM.

TATIUS, ACHILLES. See ACHILLES TATIUS.

TATTNALL, JOSIAH, 1762-1803; b. Georgia; joined the army of Gen. Wayne, 1780; appointed col., 1793; brig.-gen., 1800; was prominent in military affairs; often a member of the legislature; U. S. senator, 1796-99; governor of the state, 1800-2.

TATTAM, HENRY, D.D., LL.D., 1788-1868; b. Ireland; educated at Trinity college, Dublin, and at Göttingen and Leyden; ordained in the church of England; rector of St. Cuthbert's, Bedford, 1818-45; archdeacon of Bedford, 1844; rector of Stamford Rivers, Essex, 1849. He traveled in the east, and became distinguished as an orientalist, in which department he published various works. Among the ancient Syriac MSS. which he found at a convent in Egypt were the *Ecclesiastical History* of John bishop of Ephesus, and *Epistles of Ignatius*.

TATTERSALL'S is a famous market for riding and carriage horses situated in Grosvenor place, London. It was established about 1780 by Richard Tattersall, a groom of the duke of Kingston. At the present time it consists of a large and handsome building in the centre of which is a large court under a glass roof. It also includes tiers of large, airy stables constructed after the most approved style, and sufficient to accommodate over three hundred horses. It is a prominent rendezvous for sportsmen during the races, and it is said that the betting here regulates the betting throughout the country.

TATTNALL, a co. in s.e. Georgia; drained by the Great Ochoopee, the Cannouchee, and the Altamaha rivers, the last two being its n.e. and s. limits; about 1123 sq. m.; pop. '90, 10,253, chiefly of American birth, includ. colored. The surface is level; the soil sandy and unproductive; cotton, corn, sweet potatoes, and rice are the staples. Co. seat, Reidsville.

TATTOOING, a custom extensively prevalent among savage nations, of marking the skin with figures of various kinds, by means of slight incisions or punctures and a coloring matter. The term is of Polynesian origin, and is said to be derived from a verb *ta*, which signifies to strike. Tattooing is almost universal in the South Sea islands, except where Christianity and civilization have put an end to it. New Zealanders' heads, exhibiting tattooing, are among the curiosities to be seen in museums; and at one time it was very common for the masters of vessels visiting New Zealand to purchase them and bring them home, although there is too much reason to believe that the price paid for them stimulated the feuds of the natives. The tattooing of the New Zealanders and other South Sea Islanders often covers the whole face, and sometimes also the chest, arms, and other parts of the body with elaborate patterns. It is performed in youth, and marks the transition from boyhood to manhood, like the assumption of the *toga virilis* among the ancient Romans. The operation is accompanied with superstitious ceremonies, and is attended with considerable pain, which, of course, is to be endured with manly indifference. An instrument of bone, toothed on the edge, is employed, which is applied to the skin, and struck with a piece of wood, having first been dipped in a thick mixture made by rubbing down charcoal with a little water. The marks which result are permanent, and appear black on a brown skin; although they are dark blue on the skin of a European. Tattooing is, or has been, practiced in almost all parts of the world. It seems to be one of the practices prohibited to the Jews, in Lev. xix. 28, "Ye shall not make any cuttings in your flesh for the dead, *nor print any marks upon you*," from which may be inferred its prevalence among the surrounding tribes in the days of Moses, and its connection with their superstitions. The Bedouin Arabs, the Tunguses, and other eastern tribes, and many tribes of American Indians, practice it at the present day. Among the Bedouins, it is a favorite mode of female adornment. It prevailed among the ancient Thracians, and was distinctive of high rank. The ancient Britons also practiced it, and traces of it appear to have lingered in England till after the Norman conquest. Perhaps the practice of sailors to print anchors and other marks on their arms, may be regarded as a relic of it still subsisting.

TAU, Cross, in heraldry, a cross of a form somewhat resembling the Greek letter *Tau*. St. Anthony is generally represented with a cross of this description, embroidered on the left side of his garment.

TAUBERT, KARL GOTTFRIED WILHELM, a German pianist and composer, born in Berlin in 1811, studied philosophy at the university there, while studying composition under Berger and Klein. He taught music until 1831, when he was given the leadership of the court concerts. In 1841 he was made conductor of the royal opera. He was member of the Academy of Arts from 1839 and president of the musical section of the same from 1882. His works include the operas *The Kirmess* (1832), *Macbeth* (1857), *Cesario* (1874), music for the *Medea* of Euripides, and Shakespeare's *Tempest*. His songs were popularized by Jenny Lind and other noted singers. He died in 1891.

TAUCHNITZ, CHRISTIAN BERNHARD, Baron von, German publisher, nephew of K. C. T. Tauchnitz, born at Schleinitz, near Naumburg, in Prussian Saxony, Aug. 25, 1816. In 1837 he founded a publishing house at Leipsic, under the firm name "Bernhard Tauchnitz," which became celebrated for its critical editions of the Bible and of Greek and Roman classics, its dictionaries, juridical works, tables of logarithms, etc. He is best known to continental travelers for his convenient economic and well-printed *Collection of British Authors*, begun in 1841, and which in 1897 numbered over 3,200 volumes. In the publication of this series he adopted the principle of paying the authors for republishing their works, although at the time no international copyright laws existed. In 1866 he began a similar *Collection of German Authors*, and in 1886 the *Students' Tauchnitz Editions*, English and American works, with German introduction and notes. In 1860 he was created Baron, became British consul-general to Saxony in 1872, and was called to the house of peers in Saxony, 1877. He died at Trattlau, Saxony, Aug. 13, 1895.

TAUCHNITZ, KARL CHRISTOPH TRAUGOTT, a famous German printer and bookseller, was b. at Grosspardo, near Leipsic, in 1761. Bred a printer, he began, in 1796, a small printing business of his own in Leipsic, with which he shortly after conjoined publishing and type founding, and which, in process of time, became one of the greatest establishments of the kind in Germany. In 1809 he began the issue of a series of editions of the classic authors, the elegance and cheapness of which gave them a European circulation. By offering a prize of a ducat for every error pointed out, he was able to bring out, in 1828, an edition of Homer of extraordinary correctness. He was the first to introduce (1816) stereotyping into Germany; and he also applied it to music, which had not been attempted before. In the latter years of his busy life, he stereotyped the Hebrew Bible, and the Koran in the original Arabic. He died 1836.

TAULER, JOHN, a remarkable mystic and preacher, was b. at Strasburg about 1300, and died there June 16, 1361. About the year 1308, renouncing a considerable fortune, he entered into the mendicant order of Dominicans, and afterward studied theology in Paris, showing at that early period a predilection for speculative and mystic writings, as the scholastic philosophy and the prevailing theology of the schools did not satisfy him. Notwithstanding this tendency, his predominating practical turn of mind led him, on his return to Strasburg, to preaching and pastoral duty; and this he continued to practice with zeal and undaunted courage, even when, in consequence of the excommunication which the pope had hurled against the emperor Ludwig, the country had fallen into a state of dreadful distraction, and almost all the clergy, in obedience to the interdict issued by the bishop of Strasburg, had suspended worship. Although Tauler was now 50 years old, and had enjoyed celebrity for several years as a preacher, so powerfully was he influenced by a Waldensian of the name of Nicholas von Basel, who paid him a visit in 1340, that he gave himself up for two years to ascetic exercises and devout contemplation. Afterward, however, he betook himself more decidedly to vigorous exertions on behalf of the despised and oppressed people, and preached with wonderful power, inveighing against the avarice, ostentation, and hard-heartedness of the laity as well as of the clergy; and, although not departing from the doctrines of the church, yet fearlessly exposing its abuses, and even not sparing the pope. Thus it happened, that although he had indefatigably administered the consolations of religion in the midst of the horrors and desolation of the black death (q.v.), the bishop interdicted him from preaching, and he was obliged to quit his native town. He repaired to Cologne; but nothing further is known, either of his residence there or of his return to Strasburg, where, after a life full of toil, denial of self, and beneficence to others, he died, an old man of 60 years, and was buried in his cloister. If not the greatest German preacher of the middle ages as a whole, Tauler certainly was the greatest of his times. As his mysticism was in no way passive, but aimed at rising above the sad condition of his times and the failings of the church by inward piety and a love self-denying but at the same time active; so his style, both in his preaching and in his devotional work, was lively, impressive, picturesque, and had altogether a practical direction. Among his devotional works, the *Nachfolge des armen Lebens Christi* holds the first place. Whether the sacred hymns which bear his name really belong to him, is doubtful. Of his writings and sermons, in which he always used the German language, many have been preserved in MS.; and since 1498, numerous editions have been published, but untrustworthy, and often translated into the dialect of the place where they happened to be printed. A careful translation into new High-German has been published by Schlosser (*Predigten*, 3 vols. Frank. 1826; *Nachfolgung des armen Lebens Christi* (Frank. 1833); Schmidt, *Johannes Tauler von Strasburg* (Hamb. 1841); and Susannah Winkworth, *Life and Times of Tauler*, with 25 of his sermons translated from the German (Lond. and New York, 1857).

TAUNTON, city and co. seat of Bristol co., Mass.; on the Taunton river, and the New York, New Haven, and Hartford railroad; 36 miles s. of Boston. It was incorporated as a town in 1639, and as a city in 1864, and contains about a dozen villages. The notable buildings include the U. S. government building, Bristol co. court house, state hospital for the insane, and the public library. The city is lighted by gas, electricity, and naphtha, and has waterworks supplied from Lakeville ponds, electric street railroads connecting with Dighton, Somerset, Swansea, and Fall River, several national and savings banks, and about 20 churches. The U. S. census of 1890 reported for Taunton, 316 manufacturing establishments, employing \$7,891,382 capital, and 6,466 persons, paying \$3,141,273 for wages and \$4,799,287 for materials, and having a combined output valued at \$9,936,829. The principal manufactories are 9 large cotton mills, 10 foundries, brick and tile works, machine and printing press works, nail and tack mills, shoe button factories, copper works, a large britannia ware plant, silver-plating works, locomotive works, jewelry factory, and stove and furnace works. There are several daily, weekly, and monthly periodicals. Pop. '90, 25,448.

TAUNTON, parliamentary and municipal borough of England, capital of Somerset, is situated in the extensive and beautiful valley of Taunton Dean, or vale of Taunton, in the county of Somerset, 38 m. s.w. of Bristol in England. It communicates by railway with the Bristol and English channels. The streets are wide, well-paved, and lighted; the shops are modern and capacious, there are manufactures of silk and hosiery, and a trade in agricultural and dairy produce. Taunton is the headquarters of the Somerset archaeological and natural history society, in connection with which there is an extensive museum, placed in the ruins of the Norman castle—rich especially in fossils from the Devonian strata, and the bones of mammalia of the cave period from Mendip and

the Somersetshire gravels—and a well-conducted reading-room. There is a collegiate school founded by Bishop Fox, 1522, two dissenting colleges, several other good schools, and many charitable and other institutions. One member is returned to parliament. Pop. '91, 18,026. Ina, king of the West-Saxons, built a castle in Taunton about 700 A.D. This was soon after destroyed, but another fortress was built on the site soon after the conquest, at which period the town had a mint. In 1127, Giffard, bishop of Winchester, built and endowed a priory for the canons of St. Augustine; and in 1322 we find a house of Carmelite friars. The church of St. Mary is a magnificent specimen of perpendicular architecture, and is famous for its graceful and delicately ornamented tower. That of St. James was the conventual church of Taunton priory. The shire hall and the literary institution are handsome modern buildings. To Taunton castle Perkin Warbeck fled when he failed in storming Exeter. During the civil wars between Charles and the parliament, the town was twice besieged by Goring and twice successfully defended by Col. Blake. In Taunton, Monmouth received the heartiest welcome, and Judge Jeffreys exercised his unbounded cruelty.

TAUNUS MOUNTAINS. See NASSAU.

TAURIDA, a government of South Russia, bounded on the e., s., and s.w. by the sea of Azov and the Black sea. Area, 24,539 sq. m.; pop. '94, 1,247,159. The peninsula of the Crimea (q.v.) forms the southern portion of the government, and is connected with the northern portion by the isthmus of Perekop (q.v.) The region n. of the isthmus is flat; the Crimea contains mountain-ranges which rise upward of 5,000 feet. The only great river is the Dnieper, which forms the n.w. boundary; and the other principal streams are the Salgir and Alma in the Crimea. Among the salt lakes of the Crimea, which are very productive in salt, the lake of Sakky is celebrated for the efficacy of its waters in certain cases of disease. The climate is temperate and warm on the southern shores of the Crimea. The soil is fertile, but cultivation is carried on on a very limited scale. In the north the pasture is very rich, and cattle-breeding is the main employment of the inhabitants. In the south the mountains are clad with forests, the tobacco-plant is successfully cultivated, and fruit-growing and wine-culture are the principal occupations. The Crimean wines, the *bouquet* of which resembles that of Burgundy and the Rhenish wines, are of a very good quality. The native riches of the government, its excellent ports and harbors, promise great commercial progress. Simferopol (q.v.), in the Crimea, is the capital of the government, and Sevastopol (q.v.) and Theodosia are ports of rapidly increasing importance.

TAURINE, *Amido isathionic acid*, $C_2H_4(NH_2)SO_3H$, is a very remarkable substance occurring in the bile and in other animal products and tissues. In a state of purity it forms six-sided glistening prisms, which are perfectly transparent, neutral, devoid of odor, readily soluble in hot water, but difficult of solution in cold water, and insoluble in alcohol and ether. It does not enter into combination either with acids or bases. When heated, it undergoes decomposition, and evolves sulphurous acid, in consequence of the sulphur (upward of 25 per cent) which it contains. Taurine occurs naturally in the bile of many animals, including man. As a product of the decomposition of the bile, it may be found in the contents of the intestine and in the excrements; and in cases of jaundice it has been found in the blood, transudations, and urine. Its artificial formation has been noticed in the article **SYNTHESIS**. Its name is derived from the latin *taurus*, a bull, because taurine was first discovered in the bile of the ox.

TAUROME'NIUM. See TAORMINA.

TAURUS, MOUNT. See ANATOLIA.

TAUSIG, KARL, 1841–71; b. Warsaw; studied music under Liszt, and made a great reputation as a pianist and orchestral director. He was made court pianist at Berlin in 1865. He had an unusual musical memory, and played nearly all the chief compositions of the great masters without notes.

TAUSSIG, FRANK WILLIAM, political economist, born at St. Louis, Mo., Dec. 28, 1859. He was educated at Harvard university, from which he received the degrees of A.B., 1879; Ph.D. 1883; LL.B., 1886. He spent one year of study in Europe, and on his return was appointed professor of political economy in Harvard university. His writings include *Tariff History of the United States* (1888); *The Silver Situation in the United States* (1892); *Wages and Capital* (1896); and numerous contributions to scientific periodicals, chiefly to the *Quarterly Journal of Economics*.

TAUTOG' or BLACKFISH, *Tautoga nigra* or *Americana*, a fish of the family *labridæ* (q.v.), of the section forming the family *cyclo-labridæ* of Müller. It is found in the North American seas, and is in great request for the table. It brings a very high price in the New York market. It attains a size of 12 or 14 lbs. Its color is black on the back and sides; the belly is whitish; both jaws have a double row of strong conical teeth; the face is covered with a scaleless integument. The tautog is caught by hook and line on rocky bottoms. It is sometimes kept in ponds to fatten.

TAUTOLOGY (Gr. *tauto*, the same, and *logia*, speech) is a term used to denote the useless repetition of the same ideas in different words. It is considered one of the worst vices, whether of oral or written style, and certainly none more effectually robs language of its force and impressiveness.

TAVERNIER, JEAN BAPTISTE, BARON D'AUBONNE, a celebrated French traveler, was the son of a Flemish engraver who had settled in Paris, and was born there in 1605. The conversation of the savants who frequented his father's shop inspired him with an ardent curiosity to visit other countries, and prompted him to leave the parental roof before his 15th year. After visiting England, the Low Countries, Germany, Hungary, and Italy, he eagerly caught at the offer made to him by father Joseph (the confidant of Richelieu), to accompany two French noblemen to the east. This journey lasted from Dec., 1630, to the summer of 1633, the line of route passing through Regensburg, Dresden, Vienna, Constantinople (where he left his masters), Erzeroum, Tabriz, Ispahan, Bagdad, Aleppo, and Scanderoon, and thence by sea to Rome. Tavernier then obtained an important post in the household of the duke of Orleans, but received occasional leave of absence to prosecute his journeys in the east. Tavernier invariably traveled as a dealer in precious stones and other valuable articles of small bulk, and the great profits he realized strongly impressed upon him the advantages of regular commerce between Europe and the east. On his return to France in 1669 he was graciously received at court by Louis XIV., who presented him with "letters of nobility" in reward for his services to French commerce in India. But his prodigal expenditure and careless generosity speedily reduced his fortune, and the revocation of the edict of Nantes compelled him to take refuge in Switzerland, whence he removed to Berlin, and became director of an East India company which was projected by the elector of Brandenburg. With the view of discovering a road to the Indies through Russia, he set out from Berlin in 1688, but died at Moscow in July, 1689. An account of his travels was written for him by various parties (for Tavernier had no literary qualifications), and though full of matter valuable to the historian and geographer, it is so ill-arranged as to be in many cases almost unavailable. Tavernier was one of the most remarkable of travelers; wholly devoid of classic sentiment, he traversed the plains of Troy, and passed the ruins of Persepolis without even a flutter of interest, and partly owing to this remarkable condition of mind, his statements are distinguished by an accurate truthfulness little common among travelers. But the chief value of his book lies in the fullness and accuracy with which the nature and state of oriental commerce, the chief markets and commercial routes, and the various systems of coinage and the relations are detailed. Some of his statements concerning the conduct of the Dutch in the East Indies called forth a most virulent and abusive reply from Jurieu, the Protestant theologian, in his *L'Esprit de M. Arnauld* (1684), and a more moderate one from Van Quellenburgh; but all Tavernier's assertions which were of any moment were found to be perfectly correct. His travels were originally published in 3 vols. (two in 1676-77, and the third in 1679); they have since been several times republished, last in 1810, in 7 vols.; and have been translated into English (1678, 1684, 2 vols. 1890), Dutch (1682), and German (1684).

TAVIRA, a sea-port t. of Portugal, province of Algarve, 20 m. n.e. of Faros, pleasantly situated at the mouth of the Sequa. Tavira has decayed considerably since 1654, when, it is said, 40,000 people in the town and environs fell victims to the plague. Pop. 1890, 11,558.

TAVISTOCK, a market-town of Devonshire, picturesquely situated on the western border of Dartmoor, about 35 m. s.w. of Exeter, and 12 m. n. of Plymouth, in the fertile valley, and on the right bank, of the Tavy (whence its name), which is here crossed by two bridges within the town. Tavistock is a thriving town, with some small manufactures of serges and woolen cloths, iron-foundries and mining-works, copper, lead, tin and iron being found in considerable quantity in the neighborhood; but the population is chiefly agricultural. It is a place of considerable antiquity, and was formerly of great importance, owing mainly to its abbey, the largest and most magnificent in Devonshire, which was founded in the year 961 for the Benedictine order, by Ordgar, earl of Devonshire, father of the infamous Elfrida, and endowed with many privileges, the abbot being a peer of parliament. At the dissolution, when the revenue amounted to upward of £900, it was bestowed upon John, lord Russell, in possession of whose descendant, the duke of Bedford, the property still remains. A printing-press, the second set up in England, was established in the abbey at a very early period. The refectory and abbey gateway still exist in good preservation. The parish church is a handsome edifice, with a tower at the w. end, resting on arches, under which there is a thoroughfare. At the breaking out of the civil war Pym was member for Tavistock. Tavistock is one of the four stannary towns of the co., and is governed by a port-reeve, elected annually; a co. court is held in the town. It is connected with Barnstaple, Launceston, and Plymouth by railway, and with the river Tamar by a short canal. Sir Francis Drake was born in the immediate neighborhood in 1545, and the poet W. Browne in the town in 1590. Pop. '91, 6252.

TAVOLARA, an island in the Mediterranean Sea; off the n.e. coast of Sardinia, in lat. 40° 55' n.; called by the Romans *Bucina*. Near its eastern extremity is a lighthouse. It forms the southern coast of the Gulf of Terranova.

TAVOY, the capital of Tavoy, district in Tenasserim, British Burmah, is situated on the left bank of the Tavoy river, about 34 m. from its mouth, in lat. 14° 4' n., long. 98° 5' e. at the distance of about 162 m. w. of Bangkok. The site of Tavoy, which is low, is

inclosed on three sides by rice-fields, and on the fourth by the river. The houses are scarcely visible from the river—umbrageous trees, palms, plantains, jacks, cassias, and hundreds of flowering shrubs nearly concealing them from view. A wooden-covered pier, supported on piles, forms a convenient landing-place. There is a hospital, a large jail, and a roomy *zayat*, or caravansary. The houses, according to the universal practice of the country, are raised from the ground on piles, and are made of bamboo, fastened with rattan, and thatched with the leaf of the water-palm. Under many of the houses a loom may be observed, at which a female is generally busy at work. The shops are for the most part mere sheds or stalls, and the venders sit squatted on the raised floor in the midst of their wares. "In this little town," says a recent eye-witness, "Burman life and manners are seen in all their simplicity; and the observer cannot but be struck by the frugality, contentment, happiness, and enjoyment of life manifested by the people." The rice-fields around Tavoy are prolific sources of malaria. Intermitent fevers and dysentery are the most common diseases; but the climate is on the whole healthy, and is not considered inimical to the European constitution. According to the estimates of 1881, the population of Tavoy was 13,372. The bulk of these are true Burmans, the balance being made up with Shans and Thoughthoos, Karens, Chinese, Malays, and natives of India.

Vessels drawing not more than 12 ft. of water can reach the town of Tavoy by means of the Tavoy river. The anchorage for large ships is at Goodridge plains, about 30 m. below the town.

Tavoy used to be one of the stations in which British troops were settled, but these have been lately withdrawn. The district of which it is the capital has an area of 7200 sq. m.; and a pop. '81, of 84,988.

TAX SALES, a public sale of land, according to law, for non-payment of taxes assessed upon it. Some general principles may be stated, as running through the statutes of all or nearly all the states; but as the proceedings are regulated entirely by statute, the rights of the purchasers under, and of the original owners before such sales, the manner in which such sales are conducted, and the regulations in regard to laying taxes differ widely in different states. In the first place the assessed tax must be uncollected upon land unexempt. The land cannot be legally sold after payment or tender, either by the owner or any person whose interests would suffer by the sale. The statutory provisions before and during the sale must be exactly followed. The tax must have been properly assessed, the proper officer must have attempted to collect it, the sale must be public, duly advertised, take place at the advertised time and place, etc. The land is sold to the highest cash bidder, to whom a certificate is given, entitling him to a deed at the end of the statutory period, during which the owner may redeem, and after which a deed from the state is given to the purchaser. In a majority of the states at present this deed is *prima facie* evidence of the regularity of all the proceedings on the sale. At common law, and by the statutes of some states, it rests upon the purchaser to prove the regularity of such proceedings. In some states it must have been decided by the proper court that the taxes are unpaid, before a sale can take place.

TAX—TAXATION. This term, as expressing the exaction of money from the individual for the service of the state, is familiar to all mankind a step above barbarism; and yet few subjects are surrounded by a greater number of practical difficulties and theoretical niceties. These may be grouped under two sets of considerations—those which affect the justice of a tax, and those which affect its productiveness, and these two often tell on each other. Taxation, indeed, has so frequently been the means of perpetrating political injustice, that the term has fallen into bad popular repute. Whenever the produce of a tax is used otherwise than in the service of those who pay it, the tax is unjust. In its more oppressive form, it has been levied on conquered states, for the benefit of the conquerors, and in this shape it has sometimes been called tribute. The direction which all constitutional struggles to cleanse taxation from injustice have taken has been that of self-taxation, the community as a whole deciding on what it requires to take from the individual members for the public service. The accomplishment of this has been the chief object of all the struggles which have made a free constitution for the English races. There were old feudal dues which the monarchs had the power of exacting; but when these were insufficient for their ambitious projects, they had to ask parliament for a supply, and parliament generally took the opportunity of granting it to demand redress of grievances. It came thus to be a fundamental constitutional doctrine, that no tax can be levied save by the consent of the representatives of the people who have to pay it. The constitutional doctrine thus created by Britain was remembered by the American colonies when Mr. Grenville sought to raise there a stamp-duty and a customs-duty on tea, and the colonies revolted under the celebrated cry that "taxation without representation is tyranny!"

It was discovered, in the course of the long struggle of the house of commons to keep its hold on the purse, that the least afflictive of taxes may be the most dangerous. A fixed land-tax comes, for instance, to be no impost at all, in the afflictive sense of the term. If a thousand a year have been drawn off a certain acreage of land from time immemorial, the proprietors never possessed that part of the rents, and are no more

sufferers from not having them than from not possessing their neighbors' estates. A government with a large revenue of this kind, however, will certainly be inimical to freedom. The time when the liberties of England were in the greatest danger was the twelve years of Charles I.'s reign in which he was able to get on without going to parliament for money. The extravagance of sovereigns who wasted the domains of the crown has generally prevented them from having too formidable an influence by the possession of independent incomes. In Britain, this difficulty has been effectually guarded against, and any of the expenses of the crown which can now be paid without going annually to parliament for a vote of supply are of a very trifling character.

How to make taxation productive, is a vast and complicated practical science. Turgot, one of the wisest of financiers, called it the art of plucking the goose without making it cry. The most ingenious devices to this end, however, have often, in practice, met with counteracting difficulties. It was supposed that indirect taxation—that is, a duty levied on articles before they reach the consumer, must, in a civilized and orderly country, be almost inexhaustible. The merit of the system lay in the consideration, that the burden of the tax did not fall on the person who paid it. Income-tax, house-tax, dog-tax, and the like are levied directly on the person on whom the burden ultimately falls, and if he do not pay, the amount will be taken by force. Tea-duty, wine-duty, and the like, however, are not levied on the consumer, though he has to pay them; they are levied on the importer, who has no, or a very slight, interest against the tax, since he must charge it on the consumer. But this form of taxation is met by checks. If it is excessive, people will not buy the taxed article; and it has often been found that reducing the duty increases the revenue. An indirect tax on luxuries, and especially on those which may be used to vicious excess, has strong recommendations. In some cases, it is no great calamity should the tax throw the article nearly out of use. But then comes another check in the smuggler, whose profession may probably do more to corrupt and disorganize society than the free use of the article in which he deals. A tax on the necessities of life, on bread or salt, cannot be evaded, as in the case of luxuries, by the abandonment of use, and therefore it is very productive, but it is also very oppressive. The tax on salt in France was one of the chief causes of the French revolution. The happiest condition for the revenues of a country is when luxuries are so abundantly used by all classes that a small addition to their price is a slight burden, yet yields a large revenue. In Gt. Britain, the revenue thus derived from tea, tobacco, and stimulants may be set down in round numbers at 30 millions. The chief taxes which now form the revenue of Britain are—1. Those by old custom called “assessed,” and levied upon certain items in the possessions and enjoyments of the citizen, as his male-servants, dogs, carriages, and armorial bearings. 2. The property and income tax, which, after long disuse, was renewed in 1842, and is raised from time to time according to the exigencies of the government. 3. The customs. 4. The excise. 5. The stamps and post-office; and 6. The land-tax. See CUSTOMS-DUTIES, EXCISE, POST-OFFICE, STAMPS, LAND-TAX, FINANCE. The constitution of the United States formally vests in the general government the right of imposing taxes upon the people so far as duties on imports or exports are concerned; also requires that all bills for raising revenue shall originate in the house of representatives. No state is permitted to lay any impost or duty on imports or exports (except what may be necessary for executing its inspection laws) without consent of congress; and the net produce of all such duties and imposts is required to be for the use of the treasury of the United States. But no tax or duty can be laid by congress on articles exported from any state; nor can any capitation or other direct tax be laid, except in proportion to the authorized census or enumeration. The systems of taxation in the United States are therefore two in number: that of the national government; and that observed by the state governments, each in its sovereign capacity. Taxation by the national government is required to be uniform throughout the country; and direct taxation from this source must be apportioned to the states in accordance with their respective population. Until the war of the secession the national government relied wholly on duties on imports for funds to carry on the government; but from that time it has been found necessary to add to this source of income taxation on various domestic manufactures; and during the war an income tax was imposed. The required internal revenue taxes were placed upon the capital and circulation of banks; on beer, ale, wines, whisky, cigars, tobacco, patent medicines, cosmetics, etc.; on matches, wax-tapers, cigar-lights, etc. The table on the following page shows the receipts of the United States by taxation from March 4, 1789, to June 30, 1890:

State taxation is direct, and is either through poll-taxes upon individuals, or by assessment upon property. Not all the states levy poll-taxes, the plan being obnoxious to many. Taxation upon real estate is levied through assessment by duly appointed assessors, on proper estimates made by these officials. The custom is to assess real estate at from one-quarter to one-half its market value. Local taxes in counties, towns, cities, and school-districts are levied in accordance with general statutes or by special charter, and are apportioned in accordance with the state valuation, except as to improvements in cities, which are made chargeable on adjoining property. Taxation on personal property is levied on returns made by the persons or corporations in question. In the neces-

sary legislation toward an equitable system of taxation, certain exemptions are made, including the following: property belonging to incorporated institutions of learning endowed by private individuals; houses of worship and certain other church property; public cemeteries; personal property sufficient to cover the necessities of life; and public property, both state and national; public lands, custom-houses, school-houses, court-houses, parks, etc. The propriety of extending freedom from taxation to institutions of learning and church property is often brought in question, and powerful arguments have been employed on both sides. Inasmuch as it is very largely considered from a sentimental point of view, it is improbable that any change will soon be made on this question.

SUMMARY OF INTERNAL REVENUE RECEIPTS FROM ALL SOURCES FOR TWENTY-ONE YEARS, 1863-84.

| YEARS. | Spirits. | Tobacco. | Ferment- ed Liquors. | Banks and Bankers. | Penalties, etc. | Adhesive Stamps. | Articles and occupations formerly taxed but now exempt. |
|------------------|---------------|---------------|-------------------------|-----------------------|--------------------|---------------------|---------------------------------------------------------------------|
| 1863..... | \$5,176,530 | \$3,097,620 | \$1,628,934 | | \$27,170 | \$4,140,175 | \$26,932,763 |
| 1864..... | 30,329,150 | 8,592,099 | 2,290,009 | \$2,837,720 | 193,600 | 5,894,945 | 67,008,225 |
| 1865..... | 18,731,422 | 11,401,373 | 3,734,928 | 4,940,871 | 520,363 | 11,162,392 | 160,638,180 |
| 1866..... | 33,268,172 | 16,531,008 | 5,220,553 | 3,463,988 | 1,142,853 | 15,044,713 | 236,296,037 |

| Total in 17 yrs. | \$706,650,795 | \$466,275,123 | \$120,446,865 | \$54,427,279 | \$10,245,077 | \$177,650,960 | \$1,010,686,588 |

The total cost of collecting internal revenue in the United States for the fiscal year ended June 30, 1884, was as follows:

| | |
|------------------------------------------------------------------------------------------------------------|------------------|
| For salaries and expenses of collectors, including pay of deputy collectors, clerks, etc. | \$1,854,982 10 |
| For salaries and expenses of revenue agents, surveyors of distilleries, gaugers, and storekeepers..... | 2,438,000 00 |
| For dies, paper, and stamps..... | 454,311 69 |
| For salaries of clerks, officers, and employees in the office of the commissioner of internal revenue..... | 296,421 48 |
| For expenses of detecting and punishing violations of internal revenue law..... | 56,736 51 |
| Total cost..... | \$5,100,451 84 |
| Total collections (not including commissions on sale of stamps)..... | \$121,368,620 00 |

Experience has shown that taxes are least easily collected when reliance as to assessment has to be made on personal statements as to amount of taxable values; and when, as is the case in regard to distilled spirits, the temptation to illicit manufacture is great, or, as is the case in regard to cigars and other articles which admit of ready concealment, the element of smuggling enters into the question. Stamp duties are found to be the least onerous, the most easily collected, and to press the most equally in all directions, thus avoiding special occasion for irritation.

TAXATION OF COSTS is the checking or reviewing of the charges made by attorneys or solicitors for legal business; and there is an officer of the court provided for the purpose, called in England a master or a taxing-master, or a registrar, according to the nature of the court; in Scotland, he is called an auditor. Solicitors differ from all other professions in this, that they are treated as officers of the court, and they are not at liberty to charge what prices they please for the various services they perform. Hence, every step in a suit has a certain value put upon it by the court, and the business of the taxing-officers is to see that this standard is not transgressed.

While the term taxation of costs is retained in the legal vocabulary in the U. S., its meaning is essentially different from that which it has in England. In the U. S., after a verdict in a litigated case, the successful attorney serves upon his adversary a notice that at a certain time and place he will apply to the clerk of the court to tax the costs in the action in accordance with a statement which is given with the notice. The bill of costs includes, first, a certain sum allowed by statute to the successful party. The amounts differ in different states, but the general principle is the same. Then, the items of disbursements. If, e. g., a verdict was rendered in any N. Y. court of record for a sum of money amounting to more than \$50, the plaintiff's attorney could collect, in addition to the amount of the verdict, costs amounting to \$55, and as disbursements any sums paid in the action for witness' fees, clerk's fees, proper printing bills, sheriff's fees, etc. There are also costs on appeals, etc. The theory upon which these costs are allowed is that they are to reimburse the client for his expenses in the litigation; but as a matter of practice they are retained by the attorney. The statutory costs, however, are not given in place of compensation to the attorney, and do not affect the amount of his compensation.

TAXEL. See **BADGER**.

TAXICORNÉS, a family of coleopterous insects, of the section *heteromera*, having the body generally square; the thorax either concealing or receiving the head; the antennæ short; the legs adapted for running. Most of them are found in fungi and beneath the bark of trees. They are widely distributed over the world.

TAXIDERMY, the art of preparing the skins of animals for the purposes of the naturalist. The chief means employed in preparing the skin for stuffing in the case of small animals is to remove it carefully from the body, and, having cleaned away from it any adherent flesh, etc., to anoint it with arsenical soap; for the making of which there are several formulæ, the following being the most used: arsenic, 1 ounce; white soap, 1 ounce; carbonate of potash, 1 dram; distilled water, 6 drams; camphor, 2 drams. This keeps the skin supple, and prevents decay and the attacks of insects. The larger skins are generally prepared with a composition called preservation powder, which is made of the following ingredients: arsenic and burnt alum, each 1 lb.; powdered oak-bark, 2 lbs.; camphor $\frac{1}{2}$ lb. These substances are all reduced to a powder, mixed, and passed through a fine sieve. It requires to be carefully kept in well-stoppered bottles or jars, and when used, is thickly sprinkled over the flesh-side of the skin while still wet, and must be thoroughly rubbed in. Gloves should always be worn in this process to prevent danger from the poisonous compound. Some skins are prepared with alum only, and others with the oak-bark liquor of the tanner's pits. This, in the case of very large skins, answers very well.—Besides the mere preparation of the skin, the art of taxidermy is held to mean also the stuffing and mounting of them. This requires much personal experience, and almost every group of animals must be treated differently. See Davie, *Methods of Taxidermy* (1894).

TAY, the longest river in Scotland, draining nearly the whole of Perthshire (q. v.), and pouring into the German ocean a greater bulk of water than any other British river, has its source in the western part of the county of Perth. The Dochart, the principal feeder of loch Tay, rises in Ben Lui, on the borders of Argyleshire, and flowing in a n.e. direction, is joined by the Lochy, just before the united streams enter the lake. After leaving it, the Tay flows for some distance e.n.e., when turning southward, it passes, with a very winding course, Dunkeld (q. v.), and Perth (q. v.); about a mile below the latter place, it again changes its direction to e.n.e., widening at the mouth of the Earn (q. v.) into an estuary—the firth of Tay—which varies from three-fourths of a mile to three m. in breadth, and lies mostly between the counties of Fife and Forfar, joining the German ocean about 10 m. below Dundee (q. v.). It is navigable to Perth. Total length, 118 m.

TAYLER, JOHN JAMES, D.D., 1798–1869; b. England; graduated, university of Glasgow, 1818; minister of a Unitarian congregation at Manchester, 1820; professor of church history, subsequently of theology, in the dissenting college at Manchester; principal of the college after its removal to London, taking the name of Manchester new college; was co-pastor with Rev. James Martineau of the Unitarian congregation in Little Portland street. He published *Retrospect of the Religious Life of England*; *Christian Aspects of Faith and Duty*; *Attempt to Ascertain the Character of the Fourth Gospel*; *Catholic Christian Church the Want of Our Time*.

TAY, LOCH is a long and narrow lake in Scotland, situated in a basin scooped out of the bosom of the mountains, 355 ft. above the sea-level, in length about 15 m., and average breadth 1 m., varying from 100 to 600 ft. in depth. Ben Lawers lies on its w. side. The loch is at times subject to violent and unaccountable agitations.

TAYLOR, a co. in n. Florida; bounded on the s.w. by the Gulf of Mexico; drained by the Aucilla river; 1079 sq.m.; pop. '90, 2122. Co. seat, Perry.

TAYLOR, a co. in w. central Georgia; drained by the Flint River, which bounds it on the n.e., and by Whitewater creek; 356 sq.m.; pop. '90, 8666. Co. seat, Butler.

TAYLOR, a co. in s.w. Iowa; drained by Platte river, One Hundred and Two river, and Honey creek; 540 sq. m.; pop. '90, 16,384. Co. seat, Bedford.

TAYLOR, a co. in s. central Kentucky; watered by Robinson's creek and the Green river; 270 sq. m.; pop. '90, 9353. The surface is rolling. Co. seat, Campbellsville.

TAYLOR, a co. in n.w. central Texas; drained by a branch of the Brazos river, 900 sq. m.; pop. '90, 6756. Co. seat, Abilene.

TAYLOR, a co. in n. West Virginia; drained by Tygart's Valley river, traversed by the Baltimore and Ohio railroad; about 177 sq. m.; pop. '90, 12,147. Iron is found, and there are foundries and machine shops. Co. seat, Grafton.

TAYLOR, a co. in n. Wisconsin; formed 1875; 990 sq. m.; pop. '90, 6731. Co. seat, Medford.

TAYLOR, a magisterial dist., Orange co., Va. Pop. '90, 4787.

TAYLOR, BAYARD, American author and traveler, was the fourth child of Joseph and Rebecca (Way) Taylor, and was born at Kennett Square, Chester co., Pa., Jan. 11, 1825. His father was a descendant of an English immigrant of 1681, and his grandmothers on both sides were of German descent. His education was obtained in the

common schools and academies of the vicinity, and having no taste for farming, he was apprenticed in 1842 to the editor of the *West Chester Village Record*. He had already contributed to the *Saturday Evening Post* of Philadelphia, and secured the friendship of Rufus W. Griswold, and in 1844 he made another advance by publishing *Ximena and other Poems*. In 1844-45 he made a pedestrian tour through Europe, described in letters to the *New York Tribune*, and to Philadelphia papers, and in his *Views Afoot* (1840). He now dropped the surname "James," which a boyish fancy had led him to adopt, and on attaining his majority became joint editor, Dec., 1846, of the *Phoenixville Pioneer*, but in 1847 went to New York, where he became a writer on the *Literary World*, and subsequently one of the editorial staff of the *Tribune*, a connection retained as long as he lived. As its special correspondent he visited California and Mexico in 1849; Egypt, Syria, Asia Minor, and Europe in 1851, and in 1852 visited England and then crossed Asia to Calcutta. From there he passed to China to join the expedition of Commodore Perry to Japan. In 1857 he took as his second wife Marie Hansen of Gotha, and built a new home, "Cedarcroft." In 1862-63 he was United States secretary of legation, and later *chargé d'affaires* at St. Petersburg, and was influential in securing for the northern states the sympathy of Russia during the civil war. In 1869 he wrote an ode for the dedication of the national monument at Gettysburg. In 1874 he revisited Egypt, and in the same year attended the millennial celebration in Iceland, contributing a poem to the exercises. He wrote the ode for the opening of the Centennial Exhibition at Philadelphia, July 4, 1876, and recited it on that occasion. In Feb., 1878, he was appointed minister to Germany, where he had previously resided at intervals, and there, at Berlin, he died, Dec. 19, 1878. His body was removed to this country and buried at Kennett Square.

Taylor was a man of fine presence and attractive social qualities, and a popular lecturer, as well as author. His books of travel, besides *Views Afoot*, are, *El Dorado, or Adventures in the Path of Empire* (2 vols., 1850); *A Journey to Central Africa* (1854); *The Lands of the Saracen* (1854); *A Visit to India, China, and Japan* (1855); *Northern Travel* (N. Y., 1855); *Travels in Greece and Rome* (1859); *At Home and Abroad, a Sketch Book of Life, Scenery, and Men* (1859, 2d series, 1862); *Colorado, a Summer Trip* (1867); *By-ways of Europe* (1869); *Egypt and Iceland* (1874). His other prose works were the novels, *Hannah Thurston, a Story of American Life* (1865); *John Godfrey's Fortunes* (1864); *The Story of Kennett* (1866); and *Joseph and His Friend* (1870); *Boys of Other Countries*; *Stories for American Boys* (1876); and unfinished biographies of Goethe and Schiller. He also edited, with George Ripley, *A Handbook of Literature and the Fine Arts* (1852); a *Cyclopædia of Modern Travel* (Cincinnati, 1856), and an *Illustrated Library of Travel, Exploration, and Adventure* (vols. I.-IV. 1872-74); and translated Auerbach's *The Villa on the Rhine* (1869). His poetical works, besides *Ximena*, are, *Rhymes of Travel, Ballads, and Other Poems* (1840); *The American Legend*, a poem delivered before the Phi Beta Kappa society of Harvard University (1850); *Book of Romances Lyrics, and Songs* (1851); *Poems and Ballads* (1854); *Poems of the Orient* (1855); *Poems of Home and Travel*, selections from early lyrics (Boston, 1855); *The Poet's Journal* (1862); *The Picture of St. John* (1866); *The Ballad of Abraham Lincoln* (1869); *The Masque of the Gods* (1872); *Lars, a Pastoral of Norway* (1873); *The Prophet, a Tragedy* (1874); *Home Pastorals, Ballads, and Lyrics* (1875); *Centennial Ode* (1876); *Prince Deukalion*, a drama (1878). His translation into the original metres of both parts of Goethe's *Faust* (1870-71), is one of America's finest contributions to literature. His *The Echo Club and other Literary Diversions* (1876), contains parodies that rival the famous "Rejected Addresses" of James and Horace Smith. He also edited *Frithiof's Saga*, translated by Blackley from the Swedish of Tegnér (1867); furnished notes to the *Narrative of Perry's Expedition*, and an introduction to R. H. Stoddard's *Life of Alexander von Humboldt*. See Bayard Taylor, *His Life and Writings* (2 vols., 1884).

TAYLOR, BENJAMIN COOK, D.D., 1801-81; b. Philadelphia, graduated at Princeton college, 1819; began the study of theology with the Rev. Dr. John M. Mason, New York, and completed his course at the theological seminary of the Reformed church, New Brunswick, N. J.; pastor of the united churches of Greenbush and Blooming Grove, N. Y., 1822-25; accepted a call to Passaic, N. J.; became pastor of the Reformed church of Bergen, N. J., 1828; relieved from active duties, 1870, and made *pastor emeritus*. He published *Annals of the Classis and Township of Bergen*, and some sermons.

TAYLOR, BENJAMIN FRANKLIN, LL.D., author, was born in Lowville, N. Y., July 19, 1819. He graduated from Madison University in 1839, and became literary editor of the *Chicago Evening Journal*. During the civil war he was its war correspondent for the western armies, and his letters attracted much attention, many of them being translated and published in European papers. After the war he traveled in Mexico, and was a public lecturer for many years. He has published many books, among them *Attractions of Language* (1845); *January and June* (1853); *Pictures in Camp and Field* (1871); *Songs of Yesterday* (1877); *Between the Gates* (1881); *Dulce Domum* (1884); and *Thophilus Trent* (1887). He is best known by his poems, *The Isle of Long Ago*, *The Old Village Choir*, and *Rhymes of the River*. He died in 1887.

TAYLOR, BROOK, a celebrated English mathematician, was born at Edmonton, in Middlesex, Aug. 18, 1665, of a Puritan family of good position; entered St. John's college,

Cambridge, in 1701, at a time when mathematical science was the prominent pursuit among the learned; took his degree of LL.B. in 1709; became a fellow of the Royal society in 1712, and its secretary in 1714, in which latter year he also took the degree of LL.D. Though so young, he had become widely known in Britain and on the continent for great proficiency in mathematical knowledge, and power and versatility of mind, having already written various valuable treatises on capillary action, on the vibration of a string, on music, etc. In 1716 he visited Paris, and was received with warm demonstrations of regard by the French savans, who respected his ability and learning, and the prominent and distinguished part he had taken in the Leibnitzian controversy. On his return to England in 1717 he resumed his habits of severe study, but was forced by declining health to resign the secretaryship in 1718. For the next three years he wandered about, residing now on the continent, now in England. He died, Dec. 29, 1731, at the age of 46. Besides his earlier works above mentioned, he contributed a series of able papers on higher algebra, dynamics, and general physics, published separately his *Methodus Incrementorum* in 1715, and a *Treatise on Linear Perspective*, the first general exposition of this subject, in 1719. During the last ten years of his life he gave himself up almost entirely to metaphysical and biblical studies. His *Methodus Incrementorum* contains, besides the famous "theorem" (see TAYLOR'S THEOREM), the first germs of the calculus of finite differences, various now common forms of infinitesimal series, with mechanical, physical, and algebraical applications. The chief use made by Taylor of his theorem is in a paper (1717) entitled "Method of Approximation to the Roots of Equations." The results of his investigations may be found in the *Phil. Trans.* (1713-23), and in his two works above mentioned.

TAYLOR, EDWARD T., 1793-1871; b. Va.; was a sailor in his youth; was captured on a privateer in the war of 1812; in prison at Dartmoor, England, and chaplain to the prisoners; was ordained a preacher in connection with the New England Methodist Episcopal conference, 1819; became minister of the Seamen's Bethel, 1828. He was greatly distinguished as the sailor's preacher, and had great influence over his rough auditors by his warmth of heart, native wit, and natural eloquence. His common designation was "Father Taylor." He visited Europe in 1832 and Palestine in 1842; was chaplain to the U. S. frigate sent with relief to Ireland during the famine in 1846.

TAYLOR, GEORGE, 1716-81; b. Ireland; received a fair education, and emigrated to the United States in 1736. He was at first a common laborer in a Pennsylvania foundry, but quickly rose, and in time became a large proprietor of iron foundries in Northumberland county. In 1764 he was chosen a member of the colonial assembly, and later served in the provincial assembly for five years. He was active in aiding the movement which led to the revolution, and in 1776 became a member of the continental congress. He signed the declaration of independence.

TAYLOR, SIR HENRY, D.C.L., b. Middleham co., Durham, Eng., 1800; entered the colonial office, 1824, and was promoted to a senior clerkship, 1825. In 1873 he was knighted, in recognition of his long public services. He published *Isaac Comnenus*, a drama, 1827, which attracted little attention, but, 1834, he rose to sudden fame on the appearance of *Philip Van Artevelde*, one of the noblest historical dramas of the century. His later works have hardly added to his laurels. They include dramas, poems, and prose essays, published in the following order: *The Statesman*, 1836; *Edwin the Fair*, an Historical Drama, 1842; *The Eve of the Conquest, and Other Poems*, 1847; *Notes from Books, in Four Essays*, 1849; *The Virgin Widow, a Comedy*, 1850; *St. Clement's Eve, a Play*, 1862; *A Sicilian Summer, and Minor Poems*, 1868. An *Autobiography* of the veteran author appeared in 1885. He died in 1886.

TAYLOR, ISAAC, 1759-1829; b. London; originally a line-engraver, he removed from the metropolis, 1786, to Lavenham, Suffolk, to pursue his profession and train his children in a quiet country town; became minister of an Independent church, Colchester, Essex, 1796-1810, and at Ongar from 1810 until his death. Among his publications were many on educational subjects.

TAYLOR, ISAAC, b. at Lavenham, in Suffolk, 1787, d. at Stanford Rivers, in Essex, 1865, eminent as a Christian philosopher, artist, and mechanic, was the third of his name who attained distinction—his grandfather and father (known as Isaac Taylor of Ongar) being both named Isaac, and each in his way distinguished. Charles Taylor, the editor of *Calmet*, was an uncle, and Jane Taylor (author of the *Q. Q. Papers*) and Ann Taylor (Mrs. Gilbert of Nottingham), joint-authors of *Hymns for Infant Minds*, were sisters of the subject of this article. The literary career of Isaac Taylor extended over nearly half a century. It began in 1818, in contributions to the *Eclectic Review*, for which Robert Hall, John Foster, and Josiah Conder then wrote, and ended in 1865, in contributions to *Good Words*, in which the name of the veteran figured with those of men who were unborn when he was in the height of his reputation. Between 1822 and 1827 he published *Elements of Thought; Characters of Theophrastus*, with illustrations, etched by himself; *The History of the Transmission of Ancient Books to Modern Times; The Process of Historical Proof*, a translation of Herodotus, and the *Memoirs and Correspondence of Jane Taylor*, his sister, who has already been mentioned. In 1829 he published, anonymously, *The Natural History of Enthusiasm*, which ran rapidly through several editions; and between 1829 and 1836 he published in succession *Fanaticism*,

Spiritual Despotism, Saturday Evening, and The Physical Theory of Another Life. In 1836 appeared *Home Education*. Thereafter he was a long time occupied upon a new translation of Josephus, undertaken jointly with the Rev. Dr. Traill, and which was illustrated by etchings executed by himself. Within the last 13 years of his life appeared *Loyala, Wesley, The Restoration of Belief, Logic of Theology, Ultimate Civilization, and The Spirit of Hebrew Poetry*. Besides these numerous works, Isaac Taylor wrote many articles for the graver quarterly reviews, which are as yet uncollected. He had been educated as an artist, and some of his designs, executed before he betook himself chiefly to literature, have evoked the warmest praise from the most scrupulous critics, who have wondered how one with such a genius for art could have deserted it. It would be impossible to give here any account that would be intelligible of his numerous mechanical inventions; it must suffice to say that, by two of his inventions, he revolutionized the art of calico-printing. Isaac Taylor married in middle life, and had a large family, whose home education, as liberal-minded but pious Christians, was among, and not one of the least of, the tasks of his life.

TAYLOR, The Rev. ISAAC, M.A., canon of York Minster since 1875, the eldest son of the preceding, was b. at Stanford Rivers, May 2, 1829. He is the author of *The Liturgy and the Dissenters*, and one or two other theological pamphlets; but has best maintained the literary distinction of his family by his works on philology. His *Words and Places, or Etymological Illustrations of History, Ethnology, and Geography* (1864), of which a second edition revised and enlarged, was published in 1865, is a work of great research as well as erudition, and has done more toward the elucidation of the local names of English places than any book yet published. In *Etruscan Researches* (1874) Taylor tries to prove that the Etrurians were allied to the Turkish or Mongolian races. This proposition, however, is not well established, and the work has received severe handling from critics, especially from Prof. Max Müller. In 1876 Taylor published *The Etruscan Language*; in 1883, his great work on *The Alphabet*; in 1890, *The Origin of the Aryans*; in 1896, *Names and their Histories*.

TAYLOR, ISIDORE SÉVERIN JUSTIN, Baron, b. Brussels, 1789; studied art and became a writer and artist. Politically he sided with the Bourbons, and served in the Spanish campaign of 1823. The obelisk of Luxor now in the *Place de la Concorde*, Paris, was brought from Egypt by him. Baron Taylor also acted as purchaser of pictures for many of the great French collections, was a grand officer of the legion of honor, and he wrote several dramas and treatises on art and kindred subjects. He d. 1879.

TAYLOR, JEREMY, one of the greatest names in the English church, was the son of a Cambridge barber, and was born in that town, Aug. 15, 1613. At the age of 13 he entered Caius college as a sizar, and after seven years' strenuous and brilliant study in classics and theology, took the degree of M.A. Like Archbishop Usher, he was admitted to holy orders before he had reached his 21st year. Soon after, he attracted the notice of Laud (who had a regard for learning, if none for liberty), and was preferred by him to a fellowship at All Souls, Oxford (1636). About the same time, he was appointed chaplain in ordinary to the king; and in 1638, rector of Uppingham, a preferment which he retained till the successes of the parliamentarians deprived him of it. The first notable publication of Taylor's was a defense of the church, entitled *Episcopacy asserted* (Oxford, 1642). It procured for him the honor of D.D. During the next three years, Taylor probably accompanied the royal army; but when fortune had unmistakably declared against the king he withdrew into Wales (1645-46), and, in conjunction with Mr. W. Wynt of St. John's college, Oxford, opened a school at Newton, in Caermarthenshire. It appears to have been a pretty successful adventure, and many of his scholars, we are told, "having, as it were, received instruction from this prophet in the wilderness, were transplanted to the universities." Taylor also found a patron in the earl of Carbery, who was then living at the family seat of Golden Grove, in the same county, and who appointed him his domestic chaplain. But if this period of Taylor's life had become to the outward eye obscure and mean, it is rendered illustrious by the splendor of his literary achievements. Between 1647 and 1660, the long 13 years of his enforced seclusion, appeared all his great works, and remembering their unsurpassed merits, we are almost disposed to feel grateful to those who expelled him from his rectory, and drove him to strictly literary pursuits. In 1647, was published the *Liberty of Prophesying*, a work written on behalf of the clergy of the church of England, who were being expelled from their livings by the victorious Puritans, but in which the pleadings are based on principles far more comprehensive and tolerant than the age was disposed to acknowledge; in 1649, the *Life of Christ* (2 vols.), one of the most popular of his productions, and *The Rule and Exercises of Holy Living*; in 1651, *The Rule and Exercises of Holy Dying*, a portion of his *Sermons*, and the *Discourse of the Divine Institution, Necessity, and Sacredness of the Office Ministerial*; in 1652, a *Discourse on Baptism, its Institution, and Efficacy upon all Believers*; in 1653, 25 additional *Sermons*; in 1654, *The Presence Real and Spiritual of Christ in the Blessed Sacrament*; in 1655, *The Guide of Infant Devotion, or the Golden Grove*, and the *Unum Necessarium, or the Doctrine and Practice of Repentance*, a decidedly Pelagian treatise, which involved him in a considerable controversy; in 1657, a *Collection of Polemical and Moral Discourses, a Discourse on Friendship*, etc.; and in 1660, his famous *Ductor Dubitantium, or the Rule of Conscience in all her General Measures*, the most learned,

subtle, and curious of all Taylor's works. It was dedicated to Charles II. He was a stanch royalist, a splendid scholar, a consummate theologian, and a man of wonderful literary genius, and so it was in the nature of things almost impossible that he should escape preferment. Before 1660 had expired, he was elevated to the bishopric of Down and Connor, a dignity which he only retained some seven years, dying Aug. 13, 1667. Taylor was not happy in his Irish see. Before a year was over, he was anxious to be delivered from it as from a "place of torment." The Scotch Presbyterian ministers were "incendiaries"—they robbed him of the "people's hearts;" they even "threatened to murder" him; his only hope was in the government and the military. Altogether, it is a melancholy spectacle to behold the finest ecclesiastical genius of the time half broken-hearted by petty squabbles with intolerable fanatics, who had, nevertheless, in the points at issue between them and Taylor, something like justice on their side. No modern mind would hesitate for an instant to acknowledge that the Scots-Irish Presbyterian clergy were perfectly entitled to act as they did, and yet we fear it is too plain that the good bishop would have gladly seen them prohibited by an Episcopalian soldiery. Nay, the author of the *Liberty of Prophesying* went a step further; and on one occasion, only three months after his consecration, actually deposed 36 Presbyterian ministers occupying livings which the restoration had inconsiderately and tyrannically declared to be Episcopalian. Some very interesting information in regard to this all but unknown period of Taylor's life is to be found in *Notes and Queries* (Nov. 11, 1865).

Taylor, sometimes styled the modern Chrysostom (q.v.), on account of his golden eloquence, has no equal in the whole series of ecclesiastical writers for richness of fancy. All other divines—patristic, mediæval, and modern—show poor and meager beside him in this respect. Some are more logical, or penetrating, or profound; some grasp more clearly the spiritual significance of doctrine, or display a deeper knowledge of human nature; but Taylor ranks among the first men of his age in point of learning, subtlety of argument, elevation of devout feeling, and philosophic largeness of view, while his inexhaustible imagery, shining "like the glossy purples of a dove's neck," and full of all tender and pathetic beauty, reminds us of Spenser and Shakespeare, of Sidney and Fletcher, rather than of the somber order of theologians.—The best edition of Taylor's works is by the Rev. C. P. Eden, M.A., fellow of Oriel college, Oxford (10 vols., London, 1854).

TAYLOR, JOHN, 1580-1654; b. England a waterman on the Thames, commonly called "the water poet." He tells, in *The Pennyless Pilgrimage, or the Moneyless Perambulation of John Taylor, alias the King's Majesty's Water Poet*, "how he traveled on foot from London to Edinburgh, not carrying any money to or fro, neither begging, borrowing, or asking meat, drink, or lodging." He complains of his treatment in these frolics in his *Scourge for Baseness*. He collected in 1630 *All the Works of John Taylor, the Water Poet*.

TAYLOR, JOHN, b. in Orange co., Va., 1750; d. 20 Aug., 1824. He was educated at William and Mary College; was the successor to Richard Henry Lee in U. S. Senate, 1792, and resigned 1794. In 1797 he was presidential elector, U. S. Senator in 1803, and 1822-24. In 1798-99 he was a member of the Virginia House of Delegates, and was the mover of the celebrated "Resolutions of '98," drawn by Mr. Madison, the principles of which Taylor consistently and powerfully supported throughout his life. He wrote *An Inquiry into the Principles and Policy of the Government of the United States*; *Arator*; a series of *Agricultural Essays, Practical and Political*; *Construction Construed, and the Constitution Vindicated*; *Tyranny Unmasked*; *New Views of the Constitution of the U. S.* He was one of the ablest and purest of American statesmen, but was so ardently devoted to agriculture that it was with difficulty that he was withdrawn from its pursuits into public life. Mr. Jefferson considered his works indispensable to the library of the statesman or the philosopher.

TAYLOR, NATHANIEL WILLIAM, D.D., 1786-1858; b. Conn.; graduated at Yale college, 1807; studied theology five years with Dr. Dwight; ordained pastor of the First church (Congregational), New Haven, 1812, as successor of Moses Stuart; elected Dwight professor of didactic theology in Yale college, 1822, holding the position till his death, having in 36 years given instruction to 700 students preparing for the ministry. While a pastor he wrote a series of articles for the *Monthly Christian Spectator* on the Unitarian controversy. In 1828 he preached in New Haven the *concio ad clerum*, presenting views on native depravity which were denounced as heretical, and led to a protracted discussion between him and Dr. Tyler. After his death, four volumes of his works were edited by President Noah Porter: *Practical Sermons*; *Lectures on the Moral Government of God*, 2 vols.; *Essays, Lectures, etc., upon Select Topics in Revealed Theology*. The views for which he was attacked would now scarcely give rise to any controversy. He was a man of acute intellect and deeply evangelical spirit.

TAYLOR, RICHARD, b. Louisiana, 1826; son of President Zachary Taylor. He graduated at Yale, 1845; joined the confederate army, and commanded a Louisiana regiment at the battle of Bull Run. He served under Jackson in Virginia, with Kirby Smith in the trans-Mississippi department, and defeated Banks in the latter's Red River expedition. In 1864, then ranking as maj.-gen., he took command of the east Louisiana department, and surrendered in 1865 to Gen. Canby. He was a brother-in-law of Jefferson Davis. He pub. *Destruction and Reconstruction* (1879). He d. 1879.

TAYLOR, SAMUEL HARVEY, LL.D., 1807-71; b. New Hampshire; graduated at Dartmouth, 1833, and Andover Theological Seminary, 1831; tutor at Dartmouth, 1836-37; principal of Phillips Academy, Andover, until his death. He was unsurpassed for thoroughness as a classical teacher. From 1852 he was one of the editors of the *Bibliotheca Sacra*. Among his publications are: *Methods of Classical Study*; *Krebs' Method for Writing Latin*, from the German; *Kühner's Elementary Grammar of the Greek Language*, from the German; *Memoir of the Rev. Edward L. Parker*.

TAYLOR, STEPHEN WILLIAM, LL.D., 1791-1856; b. Mass.; graduated at Hamilton college, 1817; taught the Black River academy at Lowville, N. Y., 14 years; teacher of a private school 3 years; took charge in 1834 of the preparatory department of Hamilton institution; was professor of mathematics and natural philosophy there, 1838-45; was its president after it was organized as Madison University in 1851.

TAYLOR, TOM, 1817-80; b. England; educated at Glasgow and Cambridge. He was for two years professor of the English language and literature at University College, London; was afterward called to the bar, and for the next 21 years held various government offices. He was the author of nearly 100 dramatic pieces, among the most popular of which are; *Still Waters Run Deep*; *The Overland Route*; *Victims*; *Twixt Ace and Crown*; and *The Ticket-of-Leave Man*. He was a frequent contributor in prose and verse to *Punch*, of which he was some time editor.

TAYLOR, WILLIAM J. R., D.D., b. N. Y., 1823; son of Dr. Benjamin C.; graduated at Rutgers College, New Jersey, 1841, and at the theological seminary of the Reformed Church, New Brunswick, 1844; pastor of Reformed Church, New Durham, N. J., 1844-46; Jersey City, 1846-49; Schenectady, 1849-52; Third Reformed church, Jersey City, 1852-54; Third Reformed Church, Philadelphia, 1854-62; corresponding secretary American Bible Society, 1862-69; pastor Clinton Street Reformed Church, Newark, N. J., 1869; President of General Synod of Reformed church, 1871; editor-in-chief of *The Christian Intelligencer*, 1872-76. His church in Newark is one of the leading churches in the city.

TAYLOR, WILLIAM MACKERGO, D.D., b. Scotland, 1829; graduated at University of Glasgow, 1849; studied theology in Edinburgh; ordained pastor of the United Presbyterian Church at Kilmaurs, 1853; pastor of the United Presbyterian Church at Derby Road, Liverpool, 1855; came to the United States, 1871, as delegate of the United Presbyterian Church of Scotland to the General Assembly of the Presbyterian Church at Chicago; became pastor of the Broadway Tabernacle Church (Congregational), New York, 1872. He received the degree of D.D. from Yale College and Amherst the same day. He published *Life Truths*; *The Miracles*; *Helps to Faith, not Hindrances*—a reply to Renan's *Life of Jesus*; *The Lost Found, and Wanderer Welcomed*; *Memoirs and Remains of Rev. M. Dickie*, Bristol; *David, King of Israel*; *Elijah the Prophet*; *The Ministry of the Word*. He delivered a course of lectures in Yale divinity school on the "Lyman Beecher foundation." His preaching drew a large and attentive congregation. He died in 1895.

TAYLOR, WILLIAM ROGERS, b. R. I., 1811; entered the U.S. navy in 1828. During the Mexican War he was on the sloop *St. Mary's*, and took part in the engagement at Tampico Bar, and the siege of Vera Cruz. He served in the war of the secession, participated in the attacks on Forts Wagner and Sumter, 1863, and afterward in the attacks upon Fort Fisher. He was made rear-admiral in 1871. He d. 1889.

TAYLOR, ZACHARY, 12th president of the United States, was born in Orange co., Va., Nov. 24, 1784, son of Col. Richard Taylor, an officer of the war of independence, and one of the first settlers of Louisville, Ky., where Taylor was taken in early childhood, and grew up to his 24th year, working on a plantation, with only the simplest rudiments of education. His elder brother had received a lieutenancy in the army, and died in 1808, when Taylor was appointed to the vacant commission. In 1810 he was promoted to a captaincy; and in 1812, with 50 men, two-thirds of whom were ill of fever, he defended Fort Harrison, on the Wabash, against a large force of Indians led by the famous chief Tecumseh. Promoted to the rank of major for his gallantry, he was employed during the war in fighting the Indian allies of Great Britain. In 1822 he built Fort Jesup; in 1832 he served as colonel in the Black Hawk War; and in 1836 was ordered to Florida, where he gained an important victory over the Seminole Indians at Okeechobee, for which he was appointed brigadier general, and made commander of the United States forces in Florida. In 1840, having been appointed to the command of the southwestern department, he purchased an estate at Baton Rouge, Louisiana. On March 1, 1845, the U. S. congress passed the resolution for the annexation of Texas, formerly a province of Mexico, and for some time an independent republic. Texas claimed the Rio Grande for her southwestern boundary; Mexico insisted that there could be no claim beyond the Nueces, and prepared to defend the disputed, if she could not reconquer the whole territory. Gen. Taylor was ordered to Corpus Christi, which point he occupied in Nov. with a force of 4,000. On Mar. 8, 1846, he moved toward the Rio Grande, across the disputed territory, and built Fort Brown, opposite and commanding the Mexican port of Matamoras. Gen. Ampudia, the Mexican commander, demanded that he should retire

beyond the Nueces, pending negotiations; and on the refusal of Gen. Taylor, his successor, Gen. Arista, crossed the Rio Grande with a force of 6000. On May 8, he was defeated at Palo Alto by Gen. Taylor, with a force of 2300; and a few days after, driven from a new position at Resaca de la Palma, across the Rio Grande. War was declared by congress to exist by the act of Mexico; 50,000 volunteers were called for. Taylor made maj.-gen., re-enforced, and ordered to invade Mexico. On Sept. 9, with 6625 men, he attacked Monterey, which was defended by about 10,000 regular troops. After 10 days' siege and 3 days' hard fighting, it capitulated. Gen. Scott having been ordered to advance on the city of Mexico by Vera Cruz, withdrew a portion of the troops of gen. Taylor, leaving him only 5000 volunteers and 500 regulars, chiefly flying artillery, to meet an army of 21,000, commanded by President Santa Anna. He took a strong position at Buena Vista, fought a desperate battle, and won a decided victory. This victory, against enormous odds, created the utmost enthusiasm; and Gen. Taylor, popularly called "Old Rough and Ready," was nominated for president of the United States over Henry Clay, Daniel Webster, and Gen. Scott; and this "ignorant frontier col., who had not voted for 40 years," and was a slaveholder, was triumphantly elected over Gen. Cass, the democratic, and Martin Van Buren and Charles Francis Adams, free soil candidates. Entering upon the presidency in 1849, he found a democratic majority in congress, with a small but vigorous free-soil party holding the balance of power, while the most exciting questions connected with the extension of slavery, as the admission of California, the settlement of the boundaries of Texas, the organization of the newly-acquired Mexican territories, etc., were agitating the country, and threatening a disruption, postponed by the compromises introduced by Mr. Clay. Worn down by the unaccustomed turmoil of politics, the rough, good-natured old soldier did not long enjoy his honors. On July 4, 1850, 16 months after his inauguration, he was attacked with bilious colic, and died on the 9th.

TAYLOR'S THEOREM, so called from its discoverer, Dr. Brook Taylor (q.v.), is a general method for the algebraic development of a function of a quantity, x , in powers of its increment h , and may be thus briefly explained and illustrated: Let $f(x+h)$ denote *any* function of $x+h$ (subject to the limitations below), then $f(x+h) = f(x) + f'(x)h + f''(x)\frac{h^2}{1.2} + f'''(x)\frac{h^3}{1.2.3} + \dots$, where $f(x)$ is the same function of x , as $f(x+h)$ is of $x+h$, and $f'(x)$, $f''(x)$, etc., are the first, second, etc., differential coefficients of $f(x)$. By a supplementary theorem, due to Lagrange, who was the first to appreciate to the full the value of Taylor's discovery, it was shown that the sum of all the terms of the series after n terms, could be represented by $f^n(x+\theta h)\frac{h^n}{1.2\dots n}$, where θ is some positive fraction less than unity. The theorem supposes that between certain limits, indicated by $h=0$, and h = some finite quantity, neither $f(x)$ nor any of its derived functions vanish, or all of them do not become infinite; and the cases in which these conditions are not satisfied are often spoken of as instances of the "failure of Taylor's theorem." An important particular case of this theorem, known as *Maclaurin's*, or (more properly) *Stirling's Theorem*, was independently discovered; it is that case of the general theorem in which the various functions of x are made functions of zero, and is written $f(0+h) = f(0) + f'(0)h + f''(0)\frac{h^2}{1.2} + \dots$. The best illustrations of these theorems are the binomial, exponential, logarithmic, and circular series; thus if the function be $(x+h)^a$, then $f(x) = x^a$, $f'(x) = ax^{a-1}$, $f''(x) = a(a-1)x^{a-2}$, etc.; and by substitution of these values we obtain Newton's *binomial* theorem; if the function be $a^x + h$, Taylor's series gives us as its equivalent $a^x(1 + h \cdot \log. a + \frac{h^2}{1.2} \log. a^2 + \dots)$; and Maclaurin's gives $a^h = 1 + h \cdot \log. a + \frac{h^2}{1.2} (\log. a)^2 + \dots$, which latter is the *exponential* theorem, and may be obtained from Taylor's series by division; if the function be $\log. (1+x+h)$, ($\log. \frac{x+h}{x}$ being one of the cases in which Taylor's theorem fails), then Maclaurin's series gives the *logarithmic* theorem, $\log. (1+h) = h - \frac{h^2}{2} + \frac{h^3}{3} - \dots$; and the same theorem gives the various series expressing the values of $\sin. h$, $\cos. h$, $\sin. -h$, etc., etc. The history of this celebrated theorem is remarkable. On the first publication of the *Methodus Incrementorum*, it was entirely neglected by Leibnitz, who, in ignorance of its value, severely criticised the whole work; while the bitter hostility of John Bernoulli to British men of science, blinded him to the existence of any merit in any part of the work. The theorem never appeared in any of the works on the calculus published before D'Alembert's *Recherches*, and after that was given only in the French *Encyclopædia*; but neither D'Alembert nor Condorcet seems to have known that it was Taylor's, or to have fully appreciated its importance; and it was not till Lagrange, in the *Berlin Memoirs* for 1772, gave the name of its true author, and proposed to make it the foundation of the differential calculus, that it assumed that important position which it deserved to hold.

TAZEWELL, a co. in central Illinois, drained by the Mackinaw and Illinois rivers, the latter its n. boundary; traversed by the Chicago and Alton, the Toledo, Peoria, and Western, the Cleveland, Cincinnati, Chicago, and St. Louis, and other railroads; about 650 sq. m.; pop. '90, 29,556, chiefly of American birth. Co. seat, Pekin.

TAZEWELL, a co. in s.w. Virginia, adjoining West Virginia; drained by the Clinch, Bluestone, and Holston rivers; 536 sq. m.; pop. '90, 19,899, chiefly of American birth. Co. seat, Tazewell.

TAZEWELL, HENRY, 1753-99; b. Va.; after graduating from William and Mary college, studied law and practiced successfully in his native state. From 1775 to 1785 he was a member of the Virginia house of burgesses, and served on the committees which drew up the declaration of rights and state constitution. He was for many years a judge of the supreme court and court of appeals. In 1793 he was chosen U. S. senator, and in 1795 was president *pro tem.* of the senate.

TAZEWELL, LITTLETON WALLER, 1774-1860, was born in Williamsburg, Va. He graduated at William and Mary College in 1792; studied law and began practice in 1796. He was also elected to the state legislature in 1796, and served four years, when he was elected to Congress. In 1802 he declined re-election, and returned to his profession, where he gained exceptional distinction in criminal and admiralty law. In 1819 he was appointed commissioner for the purchase of Florida, and in 1824-'33 was in the U. S. Senate, where his speeches attracted much attention. In 1829 he declined the mission to England; was a strong opponent of nullification in 1831-'32; in '33, resigned his seat on account of his disgust with various measures; and in 1834-'36, was governor of his native state. His principal published work is a *Review of the Negotiations between the United States and Great Britain regarding Commerce* (1829). The character of "Sidney" in Wiat's *Old Bachelor* is said to be a sketch of Tazewell by his friend, the author.

T CART. Also written Tay-Cart. A kind of wagon intended for pleasure driving. It has two seats and is much used by people of fashion.

TCHAD, or TSAD, LAKE, a large lake in Soudan, northern Africa, lat. 12° 30' to 14° 30' n., long. 13° to 15° 30' east. Its size varies with the time of year; it has an area of 10,000 sq.m. in the dry season, and is sometimes four or five times as large in the rainy months. According to Rohlf's it is 1150 ft. above sea-level. The shores are low, and for the most part unattractive; and a strip of swampy ground surrounds the fine open sheet of water which is the actual Tchad, and the margin of which is lined by papyrus and tall reeds, of from 10 to 14 ft. in height.

TCHERNAIEFF, MICHAEL GREGOROVITCH, a Russian general, was born Oct. 24, 1828. He entered the military service in 1847, distinguished himself in the Crimean war, at its close was appointed chief of the staff of a division in Poland, and in 1858 was sent to Orenburg, where for some time he acted as chief of staff. Next he marched from Orenburg across the steppes of Turkestan and effected a junction with another division under Col. Verevkin, in the vicinity of the town of Tchemkend, then occupied by the Khokanians. This town Tchernaiëff took by assault in Oct., 1864, and the city of Tashkend in June, 1865. He had disobeyed orders in taking Tashkend, and although on his return to St. Petersburg he was enthusiastically received, he was from that time not actively employed in the Russian service, and retired from the army, resuming his rank only upon the Imperial request. After a year of inactivity he again retired, and purchased the *Ruski Mir*, a journal which boldly advocated Slav interests, of which he became the recognized editor in 1874. When, in 1875, the insurrection in Herzegovina broke out, he opened a subscription in its behalf, and in 1876 went to Belgrade and took the command-in-chief of the Servian army. His proclamation of Prince Milan as king of Servia was much censured at the time as a foolish act. General Tchernaiëff left St. Petersburg for Tashkend in 1882 to assume the government there, but his aggressive policy, which seemed likely to cause complications with Great Britain, led to his recall to St. Petersburg in 1884, where he became a member of the Council of War. In 1886 he was removed from office on account of indiscreet publications, but was replaced in 1890.

TCHERNIGOV', a government in s.w. Russia, drained by the Dnieper and the Desna rivers; about 20,000 sq. m.; pop. '94, 2,335,835. The surface is generally level. The soil is extremely rich. Capital, Tchernigov on the Desna, with pop. '94, 27,871.

TCHUKTCHEES, a wandering tribe in Siberia, supposed to be kin to the Koriaks, living near Behring strait.

TEA, *Thea*, a genus of shrubs of the natural order *ternstroemiaceæ*, closely allied to the genus *camellia* (q.v.), and distinguished from it only by the not deciduous calyx, and by the dissipiments remaining connected in the center of the capsule after it opens. The genus seems to derive its importance entirely from a single species, the dried leaves of which are the tea of commerce, one of the most important articles of commerce in the world, and yielding the most esteemed and extensively used of all non-alcoholic beverages. This species, the tea shrub or CHINESE TEA (*T. sinensis*), is 20 to 30 ft. high, but in a state of cultivation only 5 to 6 ft. high, with numerous branches and lanceolate leaves, which are 2 to 6 in. long. The flowers grow singly or two or three together in the axils of the leaves; they are rather large, white, and fragrant, with 5-parted calyx, 6 to 9 petals, and

many stamens. By cultivation for many centuries, numerous varieties of this plant have been produced in China, some of which have been reckoned as distinct species, particularly *T. viridis*, formerly supposed to yield green tea, *T. Bohea*, formerly supposed to yield black tea, and *T. stricta*. Of these, the first-named has the longest, and the last has the shortest leaves.

The cultivation of tea in China is chiefly confined to the regions between n. lat. 24° to 35° and e. long. 115° to 122°. Tea for domestic use is, however, cultivated both in more southern and more northern regions. The plant is to be accounted subtropical, but bears a tropical climate well, and can also accommodate itself to cold winters. In the neighborhood of London it often endures all the frost of winter without protection. In few of the countries into which it has been introduced, however, is the flavor of the dried leaf such as it is in China. The use of tea is said to have been introduced into China itself from the Corea about the 4th c. of the Christian era, and to have extended to Japan about the 9th century. The Chinese cultivate it chiefly on the southern slopes of hills. A new plantation is made by sowing the seed in holes at proper distances, two or three seeds being put into a hole to secure a plant. The first crop is obtained in the third year, when the shrub is by no means full-grown. When about seven years old, it yields only a scanty crop of hard leaves, and is cut down, when new shoots rise from the root, and bear fine leaves in abundance. This is repeated from time to time, till the plant dies at about the age of thirty years.

History and Commerce.—All that can be affirmed regarding the early history of this beverage is, that it appears to have been used for ages in China, where it is believed by the natives to be indigenous. It first became known to Europeans at the end of the 16th c., though it is only mentioned by the Portuguese writer Maffei in his *Historia Indica*, who refers to it as a product both of China and Japan. The first reference to it by a native of Britain is in a letter dated June 27, 1615, written by a Mr. Wickham, which is in the records of the East India company; and it is curious to observe that both the Portuguese and English writers referred to use their own rendering of the native name, which is *tcha*. Maffei calls it *chia*, and Mr. Wickham, *chaw*. From this time, it became gradually known to the wealthy inhabitants of London, in the form of occasional presents of small quantities from India, obtained from China, or by small lots in the markets from time to time, but always exorbitantly dear, fetching sometimes as much as £10 the lb., and never less than £5. A rather large consignment was, however, received in 1657; this fell into the hands of a thriving London merchant, Mr. Thomas Garraway, who established a house for selling the prepared beverage; and that house, under the name of "Garraway's coffee-house," is still a famous establishment in that city. From 1660 until 1689, a duty was levied on the drink made with tea at the rate of 8d. per gallon; but from the latter date a duty of 5s. per lb., with an addition of 5 per cent *ad valorem*, was levied. For many years, the duties, although occasionally changed, were always very high, and were levied by both the customs and the excise. The expiration in 1833 of the charter of the East India company, which had held a complete monopoly of the tea-trade, produced a change; the *ad valorem* duty was abolished, and differential duties of 1s. 6d., 2s. 2d., and 3s. per lb. were substituted; but they worked badly, and were abandoned in 1836 for one uniform rate of 2s. 1d. per lb., to which, in 1840, was added an additional 5 per cent.

Much mystery and error for a long time existed upon the subject of the species producing the tea of commerce. By many it was said that the qualities known as black teas were produced by the species known to botanists as *T. Bohea*, and the green teas from *T. viridis*. Others held that only one species was used to make both the black and green varieties, and that the difference arose from the method and time of preparation. The eminent botanical traveler, Mr. Robert Fortune, has, however, entirely set the question at rest by investigating the matter on the spot. He found that in the Canton district, where black teas alone are prepared, only the *T. Bohea* is grown; while in the province of Che-kiang only *T. viridis* is grown, and green teas made. But the cultivation of the latter plant he also found to be absolutely universal in the Fokien district, although the inhabitants make only black teas. The tea-farms are mostly in the n. of China, and are usually of small size, and require much attention: for the plant will only thrive in well manured or very rich soil, and the spaces between the plants, which are 4 ft. apart, must be kept in good order, and free from weeds. The farms always occupy the hill-sides, where the soil is deep and well drained. Although an evergreen, the leaves can only be gathered at certain seasons: the first is in April, when the new leaves begin to burst from the buds; and some of these in their most tender state are gathered and made into young hyson of the finest quality; so fine, indeed that it has rarely been brought to England, because it is said to lose flavor by the sea-voyage. Much is, however, sent overland to Russia, where it fetches an exorbitant price. The ordinary picking begins just after the summer rains are over, at the beginning of May; and later in the season, a third picking takes place, the produce of which is inferior, and used only by the poorer classes of the country. The later gatherings are more bitter and woody than the earlier, and yield less soluble matter to water. The leaves, when freshly plucked, possess nothing of the odor or flavor of the dried leaves, these properties being developed by the roasting which the leaves undergo in the process of drying. Moreover, different qualities of tea are prepared from the same leaves, which may be made to yield green or black teas at will.

TEA, COFFEE, ETC.—1. Tea (*Thea viridis*). 2. Cocoa (*Theobroma cacao*). 3. Lemon (*Citrus aurantium*). 4. Orange (*Citrus aurantium*). 5. Coffee (*Coffea Arabica*). 6. Orange (*Citrus aurantium*). 7. Coffee (*Coffea Arabica*). 8. Pomegranate (*Punica granatum*). 9. Pomegranate (*Punica granatum*). 10. Pomegranate (*Punica granatum*). 11. Vanilla (*Vanilla planifolia*). 12. Vanilla (*Vanilla planifolia*).

3. *Cinnamomum zeylanicum*. 4. Cinnamon (*Cinnamomum zeylanicum*). 5. Tamarind (*Tamarindus Indica*). 6. Pomegranate (*Punica granatum*). 7. Olive (*Olea Europæa*). 8. Quince (*Cydonia vulgaris*). 9. Spanish pepper (*Capnoselinum*).

For a description of the specific processes for obtaining the green and the black teas generally, we refer to Mr. Fortune's work (*Tea Countries of China*), or to Johnson's *Chemistry of Common Life*, vol i, p. 161, in which it is quoted. It is sufficient here to remark, *first*, that, in the process of drying, the leaves are roasted and scorched in such a way as necessarily to induce many chemical changes in them; the result of such changes being to produce the varieties of flavor, odor, and taste by which the different kinds of teas are distinguished; and *secondly*, that the different colors of green and black teas are due to the mode in which the leaves are treated. For *green teas* the leaves are roasted in pans almost immediately after they are gathered. After about five minutes' roasting, during which they make a cracking noise, become moist and flaccid, and give out a good deal of vapor, they are placed on the rolling-table, and rolled with the hands. They are then returned to the pans, and kept in motion by the hands: in about an hour, or rather more, they are well dried, and their color, which is a dull green, but becomes brighter afterward, has become *fixed*. The essential part of the whole operation is now over, nothing more being required than to sift and re-fire it. For *black teas*, the leaves are allowed to be spread out in the air for some time after they are gathered; they are then further tossed about till they become flaccid; they are next roasted for a few minutes, and rolled, after which they are exposed to the air for a few hours in a soft and moist state; and lastly they are dried slowly over charcoal fires, till the black color is fairly brought out. Hence the dark color and distinguishing flavor of black tea seem due to the long exposure to the atmosphere in the process of drying, and the oxygen of the air acting rapidly upon the juices of the leaf, and especially upon the astringent principle during this exposure. For the purpose of giving special scents to different varieties of tea, numerous odoriferous plants are employed in different parts of China; the cowslip-colored blossoms of the sweet-scented olive (*olea fragrans*) communicate an especially fragrant scent to tea.

The adulteration of tea, when the duty was very high, was probably carried on to a great extent; but notwithstanding the terrible tales of alarmists, it may be asserted that very little adulteration of tea is now carried on in this country. In China, spurious teas have been prepared and sent to this country under the name of "lie teas," but they had no sale, and of course were discontinued. The Chinese give an artificial coloring to the green teas sent to Europe because it pleases the eye, but the coloring matter is very innocuous, and is never produced by heating over copper plates—a popular error, which has been persisted in for a long time without a shadow of truth for its foundation. Prussian blue in very minute proportion, and a species of native indigo and gypsum, are the real materials employed for giving the face, as it is called.

In 1836 the culture of tea was attempted on a large scale in India, under the direction of the able and indefatigable botanists, Dr. Royle and Dr. Falconer; and after some difficulty, a good supply of plants was introduced to the districts of Kumaon and Gurhwal, and in the mean time plantations formed at an earlier period in Assam were making great progress. From these sources a steadily increasing supply is received, the value of which in 1880 was \$15,364,610. The quality, too, is superior to many of the Chinese teas, a fact which is testified by the large quantity of Indian teas now used. The only other country which has grown tea successfully is Brazil, where, in the high lands, tea of the most excellent quality is produced, and in sufficient quantities to supply a large portion of the Brazilian demand.

The varieties of tea are very numerous; the following are among those found in the shops of the United States:

GREEN TEAS.—*Chinese*: (1). Gunpowder sorts—viz., Shanghai, Ping-suey or pin's-head, Moyune, imperial Moyune, and Canton; (2). Hyson sorts—viz., Shanghai, Shanghai young, Moyune, Moyune young, Canton young, and Twankay or imperial Hyson. *Japanese*: Gunpowder and young Hyson. *Java*: Gunpowder.

BLACK TEAS.—*Chinese*: (1). Congo sorts—viz., Canton, Foo-chow-foo, Hung-muey, Oopack, Kaison, and Oonam; (2) Pekoe sorts—viz., plain orange, Foo-chow, scented orange, Canton scented orange, and flowery Pekoe, Oolong, and Souchong. *Assam*: Congo, orange Pekoe, and Souchong. *Java*: Congo and imperial. The latter is made up into little balls about the size of a pea, and is rare.

The use of the infusion of the leaves of tea as a beverage is general in the s.e. parts of Asia, and has become prevalent also amongst the British—at home and in all their colonies—the Americans, and the Dutch. In Scandinavia, tea is also much used by all who can afford it. In other parts of Europe the use of tea is much less general, and is chiefly confined to maritime districts, towns, and the wealthy. The importation of tea overland through Russia is inconsiderable, and the sea trade is chiefly to Britain and North America.

The *substitutes* for tea, in countries where it is difficult to obtain it, are of two sorts: those which contain theine, and which consequently have the same stimulating effect; and those which are destitute of that principle, and only resemble the true tea in flavor or smell, or which possess some other stimulating principle. Of the former class are—(1). Maté (q.v.); (2). Guarana (q.v.)—so rich is this material in theine that it has lately been used in this country for obtaining that principle; and it has been introduced into Austria and France as a powerful medicine; (3). Coffee-leaves, which are occasionally prepared as a substitute in the West Indies; they would be more gener-

ally used were it not for the disagreeable smell of the infusion; (4). the kola-nut, the active principle of which was some years ago ascertained to be theine.*

The second class, or those which do not possess that principal, are very numerous; but only a few can be said to be of any importance from being in general use in the countries producing them. These are the Siberian tea—leaves of *saxifraga crassifolia*; the Appalachian tea—leaves of *prinos glabra*; the Labrador tea—leaves of *ledum buri-folium*; the Chilian tea—leaves of *Eugenia ugni*; Trinidad pimento tea—leaves of *Eugenia pimenta*; and the leaves of the partridge-berry, which are used in some parts of North America. The Faham tea of Mauritius, and a great many more, should be regarded in the light of medicines rather than as ordinary beverages, although they are generally classed as substitutes for ordinary tea.

Tea, in its chemical, physiological, and medicinal relations.—On submitting the ordinary commercial tea to analysis, we find that it contains (1) a volatile or essential oil; (2) theine or caffeine, described in this work under the latter name; (3) a nitrogenous compound analogous to caseine or gluten; (4) a modification of tannin; besides gum, sugar, starch, fat, woody fiber, salts, etc. The volatile oil gives to tea its peculiar aroma and flavor. The proportion in which it exists is, according to Miller, about 0.79 per cent in green, and 0.6 per cent in black tea. It may be obtained by distilling the tea with water, and is found to exert a most powerfully stimulating and intoxicating effect. In China tea is seldom used until it is a year old, on account of the well-known intoxicating effects of new tea, due probably to the larger proportion of essential oil which it usually contains. The headache and giddiness of which tea-tasters complain, and the attacks of paralysis to which, after a few years, persons employed in packing tea are found to be liable, are due to the action of this oil, which according to Johnston, "does not exist in the natural leaf, but is produced during the process of drying and roasting." *Chemistry of Common Life*, 1855, vol. i.

The theine or caffeine, an alkaloid of weak basic properties, varies considerably in different kinds of tea. Peligot found it to range from 2.2 to 4.1 per cent in ordinary green teas, while very rarely it amounted to 6 per cent; whereas from the researches of Stenhouse it appears that not more than 2 per cent is usually contained in the ordinary teas in the English market. It may readily be obtained by the following simple experiment. When dry finely-powdered tea leaves, or a dried watery extract of the leaves, are put on a watch-glass covered with a paper cone, and the whole is placed upon a hot plate, or exposed to the heat of a spirit-lamp, a white vapor gradually rises and condenses on the interior of the cone, in the form of small crystals, which consist of theine. As it has no odor, and only a slightly bitter taste, it obviously has little to do with the taste or flavor of the tea from which it is extracted; it is, however, to the presence of this ingredient that the peculiar physiological action of tea on the animal economy is due. This substance is represented by the formula, $C_8H_{10}N_4O_2 + H_2O$, and is remarkable for the large quantity of nitrogen (28.83 per cent) which it contains, and which is nearly

* Dr. Daniell's observations on the kola-nut (see the article COLA-NUT) are of such importance as to demand a notice here. From time immemorial the seeds of the kola-nut have been held in inestimable value as a luxury by the inhabitants of the vast tract between the west coast and the region of Central Africa known as Sudan; and the trade in these nuts has extended to various markets on the Mediterranean. The Portuguese, Dutch, and subsequently the English voyagers, fell into the negro predilections for this fruit; and eventually the due gratification of this want became a matter of imperative necessity. Dr. Daniell's knowledge of the tonic and astringent properties of these nuts was gained during his residence on the Gold Coast, where the white inhabitants were in the habit of taking a decoction of the fresh nuts, with apparent benefit, in a particular form of endemic diarrhoea, arising more from local relaxation of the mucous membranes than from constitutional debility. On taking the medicine late, two evenings in succession, when he was afterward suffering from an attack of this kind in Jamaica, he found that he was deprived of sleep during the remainder of the night. On intermitting the decoction, the natural rest returned, and on returning to it, the insomnia again occurred. Hence he was led to suspect that a substance analogous to theine must be present; and a chemical analysis of the nuts yielded crystals in all respects resembling those of theine, and subsequently proved by the more careful investigations of Dr. Atfield to be composed of that alkaloid. Wherever the slave-trade prevailed, the tree yielding the kola-nut (*cola acuminata* of Robert Brown) followed as a matter of necessity, being imported and cultivated for the benefit of the negro. It was thus introduced into the Mauritius, Jamaica, and other West India islands, Brazil, Mexico, etc. It was specially intended to act in warding off the predisposition to epidemic outbreaks of suicidal mania, which not unfrequently almost depopulated considerable districts. While Dr. Daniell's experiments disprove the statement (alluded to in the article COLA-NUT) that these seeds render bad water palatable, his investigations, confirmed as they are by Dr. Atfield's chemical analysis, show, that whatever may be their food-value (which Dr. Daniell estimates higher, from his observations, than Dr. Atfield from their analysis), they may be advantageously substituted for coffee. See the papers by Dr. Daniell, "On the Kola-nut of Tropical West Africa," and by Dr. Atfield, "On the Food-value of the Kola-nut," in the *Pharmaceutical Journal* for March, 1865.

†The following comparative analysis of tea, coffee, and the dry kola-nut are interesting, as showing how nearly they contain the same organic constituents, although in different proportions:

| 100 Parts of tea contain | 100 Parts of Coffee contain | 100 Parts of Kola- nuts contain |
|-----------------------------|--------------------------------|------------------------------------|
| Water..... .5 | 12 | 13.65 |
| Theine..... .3 | 1.75 | 2.13 |
| Caseine.....15 | 13 | 6.33 |
| Gum.....18 | 9 } | |
| Sugar..... 3 | 6.5 } | 10.67 |
| Starch..... a trace | a trace | 42.00 |
| Tannin.....26.25 | 4 | .. |
| Aromatic oil.....0.75 | 0.002 } | |
| Fat..... 4 | 12 } | 1.52 |
| Fiber.....20 | 35 | 20.00 |
| Mineral substances..... 5 | 6.7 | 3.20 |

double the amount contained in albumen, fibrine, etc. It is also remarkable as occurring in plants very unlike each other, and growing in remote countries, which have by instinct been selected by different nations for the purpose of yielding a slightly exciting and very refreshing beverage (see above). From numerous experiments, it appears that the introduction into the stomach of a small quantity of theine (such as three or four grains, which is the quantity contained in about one-third of an ounce of good tea) has the remarkable effect of diminishing the daily waste or disintegration of the bodily tissues, which may be measured by the amount of solid constituents contained in the urinary secretion. And if the waste be lessened, the necessity for food to repair that waste will obviously be diminished in an equal proportion. "In other words," says Professor Johnston, "by the consumption of a certain quantity of tea, the health and strength of the body will be maintained in an equal degree upon a smaller supply of ordinary food. Tea, therefore, saves food—stands to a certain extent in the place of food—while at the same time it soothes the body, and enlivens the mind."—*Op. cit.* p. 173. It should, however, be stated, that the generally accepted view, that theine checks the destruction of the tissues, has been recently called in question by an excellent experimental observer, Dr. Edward Smith, in various memoirs published in the *Philosophical Transactions* and elsewhere. If double the above quantity of theine (or of the tea containing it) be taken, there is a general excitement of the circulation, the heart beating more strongly, and the pulse becoming more rapid; tremblings also come on, and there is a constant desire to relieve the bladder. At the same time the imagination is excited, the mind begins to wander, visions appear, and a peculiar kind of intoxication comes on; the symptoms finally terminating, after a prolonged vigil in a sleep arising from exhaustion. It is not definitely known what changes theine undergoes in the animal economy, but when oxidized artificially it becomes decomposed into methylamine or methyllia, $\text{CH}_3 \cdot \text{NH}_2$, hydrocyanic acid, HCN, and amalic acid, $\text{C}_{12}\text{H}_{12}\text{N}_4\text{O}_7$. The nitrogenous compound allied to caseine or gluten constitutes about 15 per cent. of the weight of the leaf. As hot water extracts very little of this substance, a large quantity of this nutritious matter, which forms about 28 per cent. of the dried spent leaves, is thrown away. Much of it might be dissolved if a little carbonate of soda were added to the boiling water with which the tea is made; and in the brick-tea (the refuse and decayed leaves and twigs, pressed into molds) used by the Tartars, most of this substance is utilized. They reduce the tea to powder, and boil it with the alkaline water of the steppes to which salt and fat have been added, and of this decoction they drink from 20 to 40 cups a day, mixing it first with milk, butter, and a little roasted meal. But without the meal, mixed only with a little milk, they can subsist for weeks on this thin fluid food. To the *astringent principle* or *tannin*, which forms from 13 to 18 per cent of the dried leaf, tea owes its astringent taste, its constipating effect upon the bowels, and its property of communicating an ink-like color to water containing salts of iron. Whether this ingredient contributes in any degree to the exhilarating, satisfying, or narcotic action of tea, is not known. Professor Johnston thinks it probable that it does exert an exhilarating effect, from the fact, that a species of tannin is the principal ingredient of the Indian betel-nut, which, when chewed, produces a mild and agreeable form of intoxication.

It is usual to judge of the quality of a tea by its aroma, and by the flavor and color of the infusion which it yields; but to these tests should be added the determination of the amount of soluble matter which it readily yields to boiling water. It is stated by Miller that our ordinary tea contains about 45 per cent of soluble matter; but the independent researches of Davy and Peligot show that boiling water seldom extracts more than one-third of the weight of the dry tea; while in J. Lehmann's experiments, only one-sixth (15.5 per cent) was extracted. Good tea should, moreover, not yield more than 5 or 6 per cent of ash when incinerated; and a portion of this is probably due to the coloring matter which the Chinese add to the green teas prepared for the foreign market. For this purpose they used to employ a mixture of Prussian blue and gypsum, but indigo is now commonly used, which is probably harmless. Drinkers of green tea who wish to know which of these adulterations they are swallowing, may easily determine the point by the following simple experiment: "If a portion of the tea be shaken with cold water and thrown upon a bit of thin muslin, the fine coloring matter will pass through the muslin and settle to the bottom of the water. When the water is poured off, the blue matter may be treated with chlorine, or a solution of chloride of lime. If it is bleached, it is indigo; if potash makes it brown, and afterward a few drops of sulphuric acid make it blue again, it is Prussian blue."

Much has been written regarding the dietetic and medical uses of tea. While some physicians have over-praised its value, others have regarded it as the source of numerous diseases, especially of the nervous system. In his admirable work on *Hygiene*, Dr. Parkes remarks that "tea seems to have a decidedly stimulative and restorative action on the nervous system, which is perhaps aided by the warmth of the infusion. No depression follows this. The pulse is a little quickened. The amount of pulmonary carbonic acid is, according to Dr. E. Smith, increased. The action of the skin is increased; that of the bowels lessened. The kidney excretion is little affected; perhaps the urea is a little lessened, but this is uncertain, the evidence with regard to the urine being very contradictory." Dr. E. Smith considers that "tea promotes all vital actions." Dr. Parkes regards it as a most useful article of diet for soldiers, and it is well known that cold tea is frequently preferred to beer or cider by sportsmen, reapers, and others

engaged in laborious work in hot weather. As a general rule, tea is very prejudicial to young children, and is not a suitable drink till growth is completed; and adults of an irritable constitution, or a leuco-phlegmatic temperament, often suffer from its use. Those with whom tea does not agree will generally find cocoa the best substitute. Old and infirm persons usually derive more benefit and personal comfort from tea than from any other corresponding beverage. In fevers, tea, in the form of a cold weak infusion, is often of great service. In persons of a gouty and rheumatic tendency, and especially in such as are of the *lithic acid diathesis* (q.v.), weak tea, taken without sugar, and with very little milk, is the best form of ordinary drink. In some forms of diseased heart, tea proves a useful sedative, while in other cases it is positively injurious; and a cup of strong green tea, especially if taken without sugar or milk, will often remove a severe nervous headache. It is nearly as powerful an antidote in cases of opium-poisoning as coffee; and very strong tea has been the means of preserving life, in cases of poisoning by tartar-emetic, the tannin being in these cases the active agent. It is impossible to speak too strongly against the habit occasionally adopted by students of keeping off their natural sleep by the frequent use of strong tea. The persistent adoption of such a habit is certain to lead to the utter destruction of both bodily and mental vigor.

The American tea trade began in the year 1784, when the first American ship sailed for China. This enterprise was followed in the next year by the dispatching of two vessels, resulting in an importation, direct, of 880,000 lbs.; and in 1786 five vessels brought more than a million pounds. The first direct importation of Japan tea was made in 1868 from Yokohama to San Francisco. The intervention of steam in the tea-carrying trade occurred first in 1867, when the Pacific mail steamer *Colorado* made a voyage to Hong Kong and Yokohama, and brought back tea to San Francisco. The time now occupied in the transportation of tea from Japan to New York is 30 to 40 days; and from Shanghai to the same port, 40 to 50 days, via San Francisco and the Pacific railroad. During the war of the secession there was levied a war-duty of 25 cents per lb. on tea; which was reduced to 15 cents in 1871, and entirely removed in the following year. The value of the tea imported into the United States in 1860 was \$8,915,327; in 1870, \$13,863,273; in 1880, \$19,782,631; in 1890, \$12,317,493.

TEACHERS COLLEGE, in New York City, a professional school for the training of teachers and the study of education. Students may become candidates for degrees in Columbia university, with which it is affiliated. Courses in manual training are offered in the Horace Mann school, a department of the college. In 1897 the faculty numbered 62, and the students 850.

TEACHING OF THE TWELVE APOSTLES, a ms. almost universally held by scholars to be of very early date, and the handiwork of an unknown follower of the first disciples of Christ. This ms. was found by Philotheos Bryennios (q.v.), Metropolitan of Nicomedia, in the library of the monastery of the Most Holy Sepulcher, Constantinople, 1873. Its discovery caused a profound sensation in the Christian world, even surpassing that which followed the publication, in 1875 (also by Bryennios), of the two Epistles of Clement, from an original ms. found in the same place. It has for its sub-title: "Teaching of the Lord through the Twelve Apostles to the Nations," and treats, in a simple and dignified manner, of certain moral laws and the observance of certain customs. Thus, the first chapters are occupied with a partial repetition of the Sermon on the Mount and of portions of the gospels. The seventh chapter enjoins baptism in the name of the Trinity, and in "living" water; but if that be "not convenient," then in other; and if cold water be not convenient, then in warm. The baptizer and the baptized are urged to fast before the baptism, the latter for one or two days. The fasting (chap. viii.) is to be on the "fourth" and on the "preparation" day, not the "second" and "fifth," like that of the "hypocrites." The Lord's prayer is to be used three times a day. Concerning the Eucharist (ix.) certain prayers are commanded, and a warning added not to admit the unbaptized to its participation. In the xvth chap., confession is urged before the "sacrifice" of the Lord's day; but whether the word here used (*a ἡραρε legomenon*) προσεξομολέω, indicates the usage of penance at the early date attributed to this ms., remains a matter of controversy. In the xvth chap., mention is made of the character of those called to be "bishops" and "deacons;" the word "priest" does not occur; "prophets," who are frequently referred to, seem to have held high rank as teachers, but possessing less important functions than the "bishops."

The consensus of scholarship is in favor of the authenticity of the Teachings. Against it is urged the saying of Eusebius: "The Teachings of the Apostles are spurious" (though it can scarcely be proved that he meant by this to assert more than that this treatise was not written by an apostle, as its name would imply); further, the baptismal customs and the Eucharistic prayer indicated differ from the known customs of the Eastern church at that time; it bears the intrinsic marks of a narrow but pious sectarianism; lastly, it is unlikely that such an exposed place as the library where this ms. was found should escape so completely the successive ravages of conquerors. These objections are more than met by the following considerations: The *Apostolical Constitutions*, VII., written before the close of the fifth century, follows it closely; Barnabas quotes from the xviii chap.; Athanasius and others refer to it; most important of all, Clement of Alexandria, in many places, uses its very language. Eusebius mentions the Teachings as among the very ancient books which occupy a place next to the canonical scriptures, classifying it with the *Acts of Paul*, *The Shepherd*, *The Revelation of Peter*, and *The Epistle of Barnabas*. Athanasius

mentions it as one of the books appointed to be read in the churches. Again, abundant proofs are brought forward to show that the Teaching antedates Barnabas, and that, therefore, the quotations referred to above are from the former and not the latter; the same holds good with the *Apostolical Canons* and *Apostolic Constitutions*. Indeed, nearly all evidences, external and internal, point to the authenticity of this treatise. However, even its strongest upholders claim for it nothing more than that it is a valuable testimony as to certain doctrines and usages of the church in a certain region, during the closing years of the apostolic age; it is in nowise set forth as of any authority. As to its date, while some place it as early as the year 70, and some as late as 165, the tendency of critical scholarship is toward the earlier date, and the period from 90 to 100 is favored by many critics.

TEAK, the name of two kinds of timber, valuable for ship-building and other purposes, one of which is known as **INDIAN TEAK**, and the other as **AFRICAN TEAK**. The trees which produce them belong to very different orders. **INDIAN TEAK** (*tectona grandis*) is a tree of the natural order *verbenaceæ*. It is found in the mountainous parts of Malabar, and elsewhere in Hindustan, and in the Eastern Peninsula, Ceylon, Java, etc. It has been introduced in some parts of India, in which it is not indigenous. Dr. Roxburgh introduced it in the low grounds of the Circars as early as 1790. It has been planted in some parts of Ceylon, but not yet with much result, as it takes 60 or 80 years to grow to a large size. It is a beautiful tree, attaining a height sometimes even of 200 ft., and rising above all the other trees of the East Indian forests. It has deciduous oval leaves of 12-24 in. long, covered with rough points; great panicles of white flowers, with 5-6 cleft corolla, and 4-celled drupes about the size of a hazel-nut. Its flowers are used medicinally in cases of retention of urine, and its leaves by the Malays in cholera. Silk and cotton stuffs are dyed purple by the leaves. The timber is the most valuable produced in the East Indies; it is light and easily worked, strong, durable, and not liable to the attacks of insects. It abounds in silex, and resembles coarse mahogany. It is extensively used for ship-building, for which purpose it is imported into Britain. All the finest ships built in India, and many built in England, are of teak. The most extensive teak forests are in Pegu. The teak generally rather grows in clumps in forests than forms forests of itself.—**AFRICAN TEAK**, sometimes called **AFRICAN OAK**, is a timber similar to East Indian teak. It is now believed to be the produce of *Oldfieldia Africana* a tree of the natural order *Euphorbiaceæ*; but the leaves of many different trees have been brought to botanists as those of the African teak.

TEAL, *Querquedula*, a genus of ducks (*anatidæ*) with very slightly lobed hind-toe, narrow bill, as long as the head, the sides nearly parallel, or widening a little at the end, the wings pointed, the tail moderately large, and wedge-shaped. Some naturalists divide the genus into two—*nettion*, in which the bill has parallel sides, and a small nail at the tip; and *querquedula*, in which it is widened, and has a larger nail. The species are numerous, the smallest of the ducks, and widely distributed over the world. They generally frequent rivers and lakes, feeding principally at night on aquatic insects, worms, mollusks, seeds, etc. The **COMMON TEAL** (*Q. or N. crecca*) is plentiful in Britain and in most parts of Europe. It is occasionally but rarely seen in North America. Its whole length is about 14 inches. It is a very beautiful bird; the head of the male brownish-red, the body transversely undulated with dusky lines, a white line above, and another beneath the eye, the speculum black and green. It makes its nest on the margins of lakes or rivers, of decayed vegetable matter lined with down, and lays eight or ten eggs. Its flesh is extremely delicate. It was domesticated by the ancient Romans, and seems capable of being advantageously introduced into our poultry yards.—The **GARGANEY** is another British species.—The **GREEN-WINGED TEAL** (*Q. or N. Carolinensis*) of North America is very similar to the common teal, but it is at once distinguished by a white crescent in front of the bend of the wings. It is occasionally seen in Europe. In its summer migrations, it visits very northern regions.—The **BLUE-WINGED TEAL** (*Q. discors*) is very abundant in many parts of North America. It is rather larger than the common teal. It is easily domesticated.

TEAR PITS. See **DEER**.

TEARS. See **LACHRYMAL ORGANS**.

TEASEL, *Dipsacus*, a genus of plants of the natural order *Dipsacæ* or *Dipsacaceæ*. This order consists of herbaceous and half-shrubby exogenous plants, with opposite or whorled leaves, and flowers in heads or whorls, surrounded by a many-leaved involucre. About 150 species are known, natives of the temperate parts of the Old World. In the genus *Dipsacus*, the flowers are separated from each other by long, stiff, prickly-pointed bracts. The only valuable species of the order is the **FULLER'S TEASEL**, or **CLOTHIER'S TEASEL** (*D. fullonum*), a native of the s. of Europe, naturalized in some parts of England. It is a biennial, several feet high, with sessile serrated leaves, the stem and leaves prickly; and with cylindrical heads of pale or white flowers, between which are oblong, acuminate, rigid bracts, hooked at the point. The heads are cut off when the plant is in flower, and are used in woolen factories, and by fullers and stockingmakers, for raising the nap on cloth. No mechanical contrivance has yet been found to equal teasel for this purpose; to which the hooked points, the rigidity, and the elasticity of the bracts are admirably adapted. The heads of teasel are fixed on the circumference of a wheel or cylinder, which is made to revolve against the surface of the cloth.

TECHE, BAYOU, in Louisiana, begins in Rapides parish, and after a s.e. course of about 175 m. empties into Atchafalaya bayou. It is navigable for small steamboats as far as St. Martinsville.

TECHNICAL EDUCATION (Gr. *techné*, art) means special instruction and training for the industrial arts. This subject has received much attention of late years in consequence of comparisons drawn between the manufactures of the United States and those of other countries shown in the great international exhibitions held in London, Paris, Vienna, and Philadelphia. Some good judges had asserted that, owing to the superior training given in continental schools to young persons in the sciences specially bearing on the arts and manufactures, other countries were making more rapid progress than our own. Whatever the state of things in 1876, it is certain that since that date marked progress has been made. The main centre of the machinery of the science and art department of Great Britain is at South Kensington. The appropriation for this department in 1890 was £474,896. In 1881, 850,000 persons received elementary art instruction; the number of provincial and elementary art schools being 32,000. Among the colleges subsidized by the department are Owens college, Manchester, Sir Josiah Mason's college, Birmingham, and Firth college, Sheffield. The government school of mines and Metropolitan school of science applied to mining and the arts was reorganized in 1881 as the Normal school of science and Royal school of mines. Its primary purpose is the instruction of teachers and of students of the industrial classes selected by competition in the science schools of the United Kingdom. Through the exhibitions attached to the yearly examinations of the science and art department, this institution places a training in science within the reach of promising students in all parts of the country, though this is exclusively theoretical. In 1878, was provisionally constituted "The City and Guilds of London institute for the advancement of technical education." Twenty-two of the Livery companies, including 9 out of the 12 great guilds, are represented on the council of the institute, and jointly contribute £21,000 annually to its funds. At first the association limited its functions to subsidizing technical education in schools and colleges in London; University and Kings, in particular, receiving grants toward the support of professorships of technical science and art. But it now has schools of its own, and has assisted those of many towns throughout the kingdom. At Kensington it has established a South London technical art school, where instruction is given in modeling, design, wood-engraving, and china-painting. In 1881, it laid the foundation of Finsbury college, in Tabernacle Row, designed to be a finishing school for those entering industrial life at a comparatively early age, a supplemental school for those already engaged in the factory or workshop, and a school preparatory to the central institution. Its departments are: mathematical and mechanical; physical; chemical; applied art. Over each department is a professor, assisted by demonstrators. There are in addition, lecturers and teachers in special subjects, and skilled artisans in the work-shops. Local technical schools have arisen in many of the smaller cities—as Manchester, Sheffield, Nottingham, etc. The head guardians of technical education laid in 1881, at South Kensington, the corner-stone of a great central institute, estimated to cost £75,000, and furnished with laboratories on the most complete scale, lecture-theaters and class-rooms. It is designed to supply a professional training to sons of manufacturers hitherto compelled to study abroad, as a finishing school for artisans trained in branch or provincial colleges, and to train a competent body of teachers. The certificates awarded by the institute on examination, are diplomas of both theoretical and practical efficiency in the subjects for which they are given. Candidates for the institute's full technological certificate must have passed the society and art department's examinations in two specified subjects in the elementary stage, and for the institute's full technological certificate with honors (required of technical teachers), two specified subjects in the advanced stage. The results of this popular education, directly and indirectly, are patent and gratifying. No Nottingham manufacturer need any longer seek a designer on the continent, but can hold his own aggressively against any lace-manufacturer in the world. At the Paris exhibition of 1878, the French saw themselves outstripped by the English in the production of some art manufactures. The European continental countries have long been making great exertions in the cause of technical education. In Paris, free instruction in art is offered to all workmen employed in certain trades. In 1881, the municipality of Paris spent £32,000 for this purpose; in 1882, still more—altogether, double the amount for its 1,900,000 inhabitants which London spent on its 4,000,000. The technical school of the École centrale, in Paris, has a new building, the cost of which was nearly £240,000. Throughout France, art and technical schools are supported by the government and the several municipalities. At Liege, Belgium, 6,000 young men are engaged nightly in the art and science schools. Switzerland and Germany are equally active, and in India there are art schools having as an object the improvement of native industries. The School of Mines at Columbia College (q.v.), New York, the Sheffield Scientific School at Yale University (q.v.), New Haven, the Stevens Institute (q.v.) at Hoboken, the Rensselaer Polytechnic Institute (q.v.), Troy, the Rose Polytechnic Institute, Terre Haute, and the Case School of Applied Science at Cleveland, are among our leading scientific schools, and from them come largely our civil and mining engineers, chemists, geologists, electricians, inventors, etc. In considering technical education as directly applied to manufactures, we must exclude these, and also a large number of art schools and associations which have not as their leading object the training of

workmen for the industrial arts. The Massachusetts Institute of Technology at Boston includes a school of mechanic arts, with a workshop conducted on the plan of the Imperial Technical school at Moscow, and the Lowell School of Practical Design, in which instruction is given in designing patterns for laces, paper hangings, and textile fabrics. The number of students in both departments in 1883 was 112. The Worcester co. Free Institute of industrial science at Worcester (incorporated 1865), has similar courses. In New York City there is a free scientific course at the Cooper Union, and in its art schools for women nearly 2,000 students yearly are prepared for industrial work. The women's institute of technical design (established 1881) has a much smaller number of pupils, but gives thorough instruction in its departments. The general society of mechanics and tradesmen, organized 1785, for the improvement of mechanics, is now a free drawing school, aiming to make mechanics more proficient, and to train designers for art industries. It admits both sexes, has a good technical reference library, gives courses of lectures every winter, and is in a prosperous condition. The New York trade school instructs mechanics in brick-laying, sanitary engineering, house and decorative painting, fresco-painting, and the art of mixing colors, and in polishing and repairing hard wood. Fifty-two young men were instructed in 1881-82. The workingmen's school, established by the society for ethical culture, combines industrial training with common school studies. The technical schools of the Metropolitan museum of art (organized about 1881) aim to furnish facilities not hitherto attainable in this country to artists and artisans, and to give thorough technical instruction in designing, decoration, modeling, carving, carriage drafting and construction, etc., and to furnish an acquaintance with the theory and practice of the arts. There is an endowment fund of \$50,000, and the carriage-builders' association contributes \$1,200 yearly to the department under its special supervision. There are at present accommodations for about 900; and about 100 students yearly attend the classes. In Philadelphia, greater interest has been awakened. The drawing school of the Franklin Institute for the promotion of the mechanic arts was established some fifty years ago, teaches "such drawing as will be useful in the workshop, and applicable to construction as well as to ornamentation," and instructs the student "to use properly his hands and his instruments." Its classes are always full. The Philadelphia School of Design for women (founded 1847) has for its object the instruction of women in decorative art, and the various practical applications thereof to industrial pursuits. It receives an annual appropriation from the state. The Spring Garden institute art school fits the pupils at any stage of the instruction to do useful work in the mechanic arts, or, if they complete the course, to become draughtsmen, architects, designers, artists, or teachers of drawing. The public school of industrial art (organized 1881, by and now under the direction of Mr. Charles G. Leland), receives its pupils (12-16 years of age) from the public grammar schools; and among the branches taught are wood-carving, modeling in clay with color and glaze, carpenter's work, cabinet-making, mosaic work and marquetry. The practical results have been most gratifying. The Ohio mechanics' institute, Cincinnati, organized 1828, for the instruction of apprentices in mechanical, architectural and artistic drawing, has recently become a school of technology. It reported in 1882, 280 pupils (males). The Cincinnati museum association incorporated 1881, has erected a fine building at a cost of \$50,000, on land given by the city, has endowment funds of over \$460,000, and, forming its museum on the plan of that at South Kensington, promises, through its schools of science and art, to work important changes in the quality of the goods and articles manufactured in the state. The Maryland Institute for the promotion of the mechanic arts at Baltimore (organized 1848), aims particularly to furnish the most thorough instruction in the various branches of art to persons wishing to become professional designers, decorators or skilled artisans. Number of pupils in the day school, 1883, 177; in the night school, 497. Illinois Industrial University at Urbana, offers a two years' course in industrial art, and a more advanced course for those wishing to become teachers or designers. Although mechanical drawing is taught in the schools of many of our larger cities, no systematic attempt has been made, unless it is in Massachusetts, to furnish this instruction with a view to future profit to the commonwealth; and in Massachusetts alone, is there a state normal art school (established 1873), for the training of teachers and masters for the industrial drawing schools of the state. See MANUAL TRAINING.

TECHNIQUE (German, *Technik*), a French term which signifies the mechanical part of instrumental playing.

TECHNOLOGY (Gr. *techné*, art) is the name given to the science or systematic knowledge of the industrial arts. In its widest sense, it would embrace the whole field of industry, but it is restricted in usage to the more important manufactures (spinning, weaving, metallurgy, brewing, etc.). Technology is not an independent science, having a set of doctrines of its own, but consists of applications of the principles established in the various physical sciences (chemistry, mechanics, mineralogy, etc.) to manufacturing processes. A complete course of instruction in technology could only be of the most superficial kind. The essential preparation for any branch of the manufacturing arts is the study of the fundamental physical sciences which are taught in schools and universities; and the special applications to the branch which the student has to pursue professionally can best be learned from special treatises on the subject in connection with practice in a manufacturing establishment. See TECHNICAL EDUCATION.

TECK, a duchy situated in Swabia during the middle ages. It derived its name from the castle of Teck, the ruins of which are still in existence. The house of Hapsburg gained possession of it in the 11th c., and sold it in the 14th c. to the dukes of Würtemberg.

TECK (PRINCE AND DUKE OF), FRANCIS PAUL CHARLES LOUIS ALEXANDER, Count of Hohenstein, only son of Duke Alexander of Würtemberg and the Countess Hohenstein, was born Aug. 27, 1837. As the marriage of his mother to Duke Alexander was only recognized as morganatic by the German law, he bore the title of Count of Hohenstein until a decree of the King of Würtemberg in 1863 conferred on him the title of Prince Teck. He served in the Austrian army, but resigned his commission in 1860. He married Princess Mary Adelaide of Cambridge, June 12, 1866. She died 1897.

TECUMSEH, or **TECUMTHA**, about 1768-1813; chief of the tribe of Shawnees; b. near the site of Springfield, Ohio. With his brother, Elskwatawa, who claimed the gift of prophecy, he attempted to form an alliance of all the western tribes against the whites. A village of about 400 warriors was gathered at Greenville, and they were ordered to remove by Gen. Harrison, who was then governor of the territory of Indiana. Various hostile movements on the part of Tecumseh's forces led to the battle of Tippecanoe, Nov. 7, 1811. Harrison was at the head of about 800 men, and was attacked by Tecumseh in his own camp. The whites repulsed and defeated the Indians. Before a treaty had been concluded with the tribes, the war of 1812 broke out and Tecumseh allied himself to the British forces. He took part in the battles on the Raisin river and at Maguaga; was wounded in the latter, and made brig.gen. in the British forces for his services. At Fort Meigs he showed humanity in his treatment of prisoners. The field of battle at the Thames was selected by Proctor and Tecumseh, the latter commanding the right wing. He was killed while fighting desperately. A life of the great Indian chief was written, 1841, by Benjamin Drake.

TE DEUM (*Te Deum laudamus, Te Dominum confitemur*), a well-known hymn (so called from its first words) of the Roman Catholic church, sung on all occasions of triumph and thanksgiving, and a theme upon which the most celebrated composers have from time immemorial exercised their musical genius. The hymn is one of the most simple, and at the same time the most solemn and majestic, in the whole range of the hymnology of the Roman Catholic church. Its authorship is uncertain. An ancient chronicle (long posterior, however, to the supposed date of the composition of this hymn, and otherwise destitute of authority) describes the *Te Deum* as the joint production of Sts. Ambrose and Augustine, into which they both burst forth by a common inspiration on occasion of the baptism of Augustine. From this supposed origin, the *Te Deum* is commonly called the Ambrosian hymn. It is ascribed by other authorities to Hilary of Poitiers, but is most probably considerably later. Besides its general use on occasions of joyous celebrations, the *Te Deum* forms part of the daily "matins" of the Roman breviary, and is recited at the end of "matins" on all festivals, and on all Sundays except those of Advent and Lent, to which, as being seasons of penance, the *Te Deum* is considered inappropriate. Its use is very ancient. It is universally admired by Protestants as well as Roman Catholics, and exhibits none of the peculiarities of Roman Catholic theology.

TEEL-SEED. See OILS and RAM-TIL.

TEES, a river in the n. of England, is 90 m. long, flows east, forming the boundary between the counties of Durham (q.v.) and York (q.v.), and falls into the North sea, 10 m. below Stockton, to which town it is navigable for vessels of 60 tons burden.

TEETH, **THE**. A tooth is described by Prof. Owen, the highest authority on this subject, as "a hard body attached to the mouth or commencement of the alimentary canal, partially exposed when developed. Calcified teeth are peculiar to the vertebrates, and may be defined as bodies primarily, if not permanently, distinct from the skeleton, consisting of a cellular and tubular basis of animal matter containing earthy particles, a fluid, and a vascular pulp."—*The Anatomy of Vertebrates*, 1866, vol. i. p. 359. "They present," says the same writer, "many varieties as to number, size, form, structure, position, and mode of attachment, but are principally adapted for seizing, tearing, dividing, pounding, or grinding the food.* In some species they are modified to serve as formidable weapons of offense and defense; in others, as aids in locomotion, means of anchorage, instruments for uprooting or cutting down trees, or for transport and working of building materials. They are characteristic of age and sex; and in man they have secondary relations, subservient to beauty and to speech. Teeth are always intimately related to the food and habits of the animal, and are therefore highly interesting to the physiologist; they form, for the same reason, important guides to the naturalist in the classification of animals."—*Circle of the Sciences; Organic Nature*, vol. i. p. 264.

True teeth consist of one, two, or more tissues, differing in their chemical composition and in their microscopical appearances. "Dentine," which forms the body of the tooth, and "cement," which forms its outer crust, are always present; the third tissue, the "enamel," when present, being situated between the dentine and cement. The *Sentine*, which is divided by Prof. Owen into hard or true dentine, vaso-dentine, and

* Hence the division of the teeth into incisors, or cutting teeth; molars, or grinding teeth; etc.

osteo-dentine, consists, according to that physiologist, of an organized animal basis, disposed in the form of extremely minute tubes and cells, and of earthy particles; these earthy or calcareous particles being either blended with the animal matter of the interspaces and walls of the tubes and cells, or contained in a minutely divided state in their cavities. The tubes and cells contain, besides the calcareous particles, a colorless fluid, which is probably transuded blood plasma, or *liquor sanguinis*, and contributes to the nutrition of the dentine. In hard or true dentine, the *dental tubes* proceed from the hollow of the tooth known as the *pulp cavity*, in a slightly wavy course, nearly at right angles to the outer surface. "The hard substance of the tooth is thus arranged in hollow columns, perpendicular to the plane of pressure, and a certain elasticity results from these curves; they are upright where the grinding surface of the crown receives the appulse of the opposing tooth, and are horizontal where they have to resist the pressure of contiguous teeth. The tubuli, besides fulfilling the mechanical ends above stated, receive the plasma transuded from the remains of vascular pulp, which circulates by anastomosing branches of the tubuli through the dentine, maintaining a sufficient, though languid vitality of the system. The delicate nerve-branches on the pulp's surface, some minute production of which may penetrate the tubuli, convey sensations of impressions affecting the dentine—sensations of which every one has experienced the acuteness, when decay has affected the dentine, or when mechanical or chemical stimuli have "set the tooth on edge;" but true dentine has no canals large enough to admit capillary vessels with the red particles of blood." When a part of the primitive vascular pulp from which the dentine is developed remains permanently uncalcified, red blood is carried by "vascular canals" into the substance of the tissue. Such dentine is called *vaso-dentine*, and is often combined with true dentine in the same tooth, as, for example, in the large incisors of certain rodents, the tusks of the elephant, and the molars of the extinct megatherium. Another modification of the dentine is when the cellular basis is arranged in concentric layers around the vascular canals, and contains "radiated cells," like those of bone; this is termed *esteo-dentine*, and resembles true bone very closely. The *cement* always corresponds in texture with the osseous tissue of the same animal, and wherever it occurs in sufficient thickness, as on the teeth of the horse or ox, it is traversed like bone by vascular canals. Moreover, when the osseous tissue contains minute radiated cells, precisely similar cells are likewise present in the canal, and constitute its most marked characteristic. The relative densities of dentine and cement vary according to the amount of earthy matter. In the complex grinders of the elephant and some other animals, the cement, which forms nearly half the mass of the tooth, wears down sooner than the dentine. The *enamel* is the hardest of all the animal tissues, and contains no less than 96.4 per cent of earthy matter (mainly phosphate of lime), while dentine contains only 72 per cent, and cement and ordinary bone 69 per cent of earthy matter. The earthy matter is contained in comparatively wide canals, composed of animal membrane of extreme tenuity.

In tracing the teeth upward from their simplest to their most complicated forms, we find a very few examples (solely among fishes—as, for example, the wrasse), in which teeth consist of a single tissue—a very hard kind of non-vascular dentine. Teeth consisting of dentine and vaso-dentine are very common in fishes, the hard dentine being external, and performing the office of enamel. Dentine and cement, the latter forming a thick outer layer, constitute the grinding teeth of the dugong. In the teeth of the sloth, the hard dentine is reduced to a thin layer, and the chief bulk of the tooth consists of vaso-dentine internally, and a thick crust of cement externally.

"The human teeth and those of the carnivorous mammals appear at first sight to be composed of dentine and enamel only; but their crowns are originally, and their fangs are always covered by a thin coat of cement. There is also commonly a small central tract of osteo-dentine in old teeth. The teeth called compound or complex in *mammalia* differ as regards their composition from the preceding only by the different proportion and disposition of the constituent tissues. Fig. 1 is a longitudinal section of the incisor of a horse; *d* is the dentine, *e* the enamel, and *c* the cement, a layer of which is reflected into the deep central depression of the crown; *s* indicates the colored mass of tartar and particles of food which fills up the cavity, forming the 'mark' of the horse-dealer."—*Organic Nature*, vol. i. p. 267. Far more complex forms of teeth than this may be produced by peculiar arrangements, chiefly inflections, of the tissues. Certain fishes, and a family of gigantic extinct batrachians, to which Owen has, from this remarkable peculiarity, given the name *labyrinthodons* (q.v.), exhibit this kind of complexity in a remarkable degree. Another kind of complication is produced by an aggregation of many simple teeth into a single mass. These compound teeth are most common in fishes, but are occasionally met with in mammals. The teeth of the Cape ant-eater (*oryzomys*), depicted and described by Owen in *The Circle of the Sciences*, are of this kind, each tooth being composed of a congeries of long and slender prismatic denticles of dentine, which are cemented together. In the ele-

FIG. 1.—Longitudinal section of the incisor of a horse.

phant, the compound molars belong to this class, the denticles being in the form of plates vertical to the grinding surface, and transverse to the long diameter of the tooth. When the tooth is bisected vertically and longitudinally, the three substances, dentine, cement, and enamel, are seen blended together.

Our limited space forbids our entering into any details regarding the teeth of fishes, further than to remark that, in regard to their number, form, substance, structure, situation, or mode of attachment, they offer a greater and more striking series of varieties than do those of any other class of animals. In all fishes, the teeth are shed and are renewed, not once only, as in mammals, but frequently during the whole course of their lives; and, as Prof. Owen observes, "this endless succession and decadence of the teeth, together with the vast numbers in which they often co-exist in the same fish, illustrate the law of vegetation or irrelative repetition, as it manifests itself on the first introduction of new organs in the animal kingdom." While comparatively few fishes are entirely devoid of teeth, we find that in the class of reptiles, the whole order of *chelonina* (tortoises and turtles), the family of toads (*bufonidae* in the order of *batrachia*), and certain extinct genera of *sauria* (lizards) are toothless. Frogs have teeth in the upper, but not in the lower jaw. Newts and salamanders have teeth in both jaws and upon the palate; and teeth are found on the palate as well as on the jaws of most serpents. In most lizards, and in crocodiles, the teeth are confined to the jaws. The teeth in reptiles are for the most part simple, of a conical form, and adapted, as in the case of most fishes, for seizing and holding, but not for dividing or masticating the food. In no reptile does the base of the tooth branch into fangs; and, as a general rule, the base of the tooth is ankylosed to the bone which supports it. The completion of a tooth is soon followed by preparation for its removal and succession, the faculty of developing new tooth-germs being apparently unlimited in this class. For further details regarding the teeth of fishes and reptiles, the reader is referred to Prof. Owen's invaluable *Anatomy of the Vertebrates*, 1866, vol. i. pp. 359-409. Birds having no teeth, we proceed to the consideration of the dental system of mammals—a class which includes a few genera and species that are devoid of teeth. The true ant-eaters (*myrmecophaga*), the pangolins or scaly ant-eaters (*manis*), and the spiny monotrematous ant-eater (*echidna*), are strictly toothless. The ornithorhynchus has horny teeth, and the whales (*balena* and *balænoptera*) have transitory teeth, succeeded in the upper jaw by whale-bone. The female narwhal exhibits nothing more than the germs of two teeth in the substance of the upper jaw; in the male, one of these germs becomes developed into the remarkable weapon which specially characterizes the animal, and to which its generic term *monodon* (single tooth), is due. In the great bottle-nose whale, in the adult state, there are only two teeth (here occurring in the lower jaw); whence the name *hyperoödon bidens*. The elephant has never more than one entire molar, or parts of two, in use on each side of the upper and lower jaws; to which are added two tusks, which are modified incisors, more or less developed, in the upper jaw. Some rodents have two grinders on each side of both jaws, which, added to the four cutting-teeth in front, make 12 in all; but the common number of teeth in this order is 20, although hares and rabbits have 28 each. The number of teeth, 32, which characterizes man, the apes of the old world, and the true ruminants, is the average one of the class mammalia; but according to Prof. Owen, "the typical number is 44." "I have been led," he observes, "chiefly by the state of the dentition in most of the early forms of both carnivorous and herbivorous mammalia which flourished during the eocene tertiary periods, to regard three incisors, one canine, and seven succeeding teeth on each side of both jaws, as the type-formula of diphyodont* dentition."—*On the Classification and Geographical Distribution of the Mammalia*, 1859, p. 18. A few of the monophyodonts possess from 80 to 100 teeth. See the article MAMMALIA. The hog, the mole, the gymnure, and the opossum, are among the few existing quadrupeds which retain the typical number and kinds of teeth. The formula expressing the number of the different kinds of teeth—viz., the incisors or cutting-teeth, the canines or dog-teeth, the premolars, and the molars or true grinder, commonly known as the *dental formula*, is described in the article DENTITION, in which the *milk* or *deciduous* teeth, and the order in which they appear, are also described. It is only in the mammals that we have a well-marked division of the teeth into the four kinds of incisors, canines, premolars and molars, each of which claims a brief description.

The *incisors*, or cutting-teeth, are situated in front, and possess a single conical root or fang, and a vertical crown beveled behind, so as to terminate in a sharp cutting edge. These teeth are specially fitted, as their name implies, for cutting the food. In man, there are two of these incisors in each side of each jaw. In herbivorous animals, they crop the herbage; in rodents (the rabbit, hare, rat, beaver, etc.), these teeth are very much developed, and differ from any other teeth occurring in mammals in this respect, that their growth continues throughout life; and if their length does not con-

* Professor Owen divides the class mammalia, in regard to the times of formation and the succession of their teeth, into the *monophyodonts* (Gr. *mōno*, once; *phý*, generate; and *odont*, tooth), or those that generate a single set of teeth, as the sperm whales, dolphins, porpoises, armadillos, and sloths; and the *diphyodonts* (derived from *di*, twice, etc.), or those that generate two sets of teeth, as the mammals generally, with the above exceptions.

stantly increase, it is because their free extremity or edge is worn down by trituration as fast as they grow at the base from their roots.

The *canines* (so called from their prominence in the dog) come next to the incisors. Their crown is rather conical than wedge-shaped, and their fang sinks more deeply into the jaw than in the case of the incisors. In all carnivorous animals, they are largely developed, being obviously formed for tearing the flesh of their prey. In man, there is one canine tooth in each half-jaw; and there is never more than this number in any of the lower animals.

The *premolars* (known also as bicuspid and false molars) come next in order to the canines; they are smaller than the latter, and their crown presents two pyramidal eminences. In man, there are two premolars in each half-jaw. Their function more nearly approaches to that of the true molars behind them, than to that of the canines.

The *true molars* (or multicuspid) are placed most posteriorly. They are remarkable for their comparatively great size, the square form of the upper surface, on which are from three to five elevations or cusps, and for their short root, which is divided into from two to five branches, each of which is perforated at its extremity. In man there are three molars in each half-jaw, the posterior one being termed the wisdom-tooth from its being cut the latest; they are especially employed for grinding the food, under the action of the muscles of the lower jaw.

The teeth are so admirably adapted for the special purposes which they are called upon to fulfill, that it is generally easy, from a careful examination of them, to say to what class of animals they belong, and to draw various conclusions regarding the habits and structure of the class generally. Thus, in carnivorous animals, the molars are not grinding teeth, but present sharp cutting edges, and those of the upper and lower jaw overlap each other; resembling a pair of scissors in their action. In insectivorous animals, the molars have a tuberculated surface, with conical points and depressions, so arranged as to look into each other. In frugivorous animals, living on soft fruits, these teeth are provided with rounded tubercles, while in herbivorous animals, they have a broad, rough surface, resembling a millstone.

There is also a close connection between the articulation or joint of the lower jaw and the nature of the food used by the animal. Thus, in purely carnivorous animals, in which the teeth simply tear and cut the food, no grinding motion is required, and the jaw is capable only of a simple hinge-motion in the vertical plane; while in herbivorous animals, the joint is so constructed as to allow of extensive sliding and lateral motion of the lower molar teeth upon the upper. In man, both the form of this articulation and the general character of the teeth point to an intermediate position in relation to food, and form a good physiological argument for the mixed diet which general custom has decided to be most favorable and natural to our species.—For further information on this subject, the reader is referred, not only to the three works of the professor from which quotations have been made in this article, but to his splendid *Odontography* (1844), and to his article "Teeth," in *The Cyclopædia of Anatomy and Physiology*; to F. Cuvier, *Sur les Dents*, etc., and to De Blainville's *Osteographie*.

DISEASES OF THE TEETH.—The dangers to which infants and children are exposed during the process of teething, are noticed in the article DENTITION; and we shall therefore here confine our remarks to the affections of permanent teeth, of which the following are the most important:

1. *Caries of the teeth*, usually commences in the dentine immediately below the enamel, a yellow or brown spot being observed on the surface of the tooth over the affected part. The tissue soon becomes softened, and a small cavity is formed, which, after a time, presents an external opening, in consequence of the unsupported enamel giving way. The substance of the tooth now decays more rapidly, and the caries gradually approaches the central or pulp cavity, which at length is opened. Hitherto, there has been little or no suffering, but now pain is experienced under the action of irritant substances, heat, cold, etc. Inflammation proceeding to suppuration takes place; the pulp is gradually destroyed by ulceration; and the body of the tooth, thus deprived of its nourishment, decays and leaves nothing but the outer coating of enamel, which then breaks away by degrees, till nothing but the fangs of the tooth remain, and these usually cease to give pain. Caries is not only a common cause of toothache, but frequently gives rise to obstinate headache, pain in the ear, deafness, squinting, impossibility of bearing the light (photophobia), and other anomalous symptoms, which immediately disappear upon the removal of the diseased tooth. In these cases, the tooth may never have ached, but will be found painful when pressed up or smartly struck. The primary cause of caries is constitutional, and it especially occurs in scrofulous and ill-nourished persons, or in those whose health is broken down by too frequent pregnancies, prolonged lactation, the abuse of mercury, etc. The direct or exciting causes are usually described as: (1) Such as destroy the integrity of the enamel, and thereby expose the dentine to the influence of irritant substances; or (2) such as operate upon the vital susceptibilities of the dental tissues. Among the former are acids and other corrosive substances taken into the mouth, sour eructations, the attrition of opposing surfaces of the teeth, and all kinds of mechanical violence; while among the latter may be mentioned hot and cold drinks, especially when taken in quick alternation. The excessive use of sugar is also commonly regarded as a cause of the disease. Many of the best dentists,

however, deny that acids (when taken medicinally) or the abrasion of the enamel can give rise to caries.

With regard to treatment, it may be observed that if the caries be slight and recent, the decayed portion must be removed, and the cavity filled up with gold, as described in the article DENTISTRY. "But," says Dr. Druitt, who on dental matters always quotes the opinion of Mr. Tomes, one of the greatest scientific authorities on the diseases of the teeth, "if the decay has advanced far toward the pulp cavity, or has laid that open, it may be necessary first to employ aperients and tonics, and use some application to deaden the sensibility of the tooth, so as to enable it to bear the stopping, and to protect it meanwhile from contact with food and saliva." Many a useless visit to the dentist might be avoided, if the patient would take an aperient dose of epsom salts two or three consecutive mornings; and after cleansing out the cavity with dry cotton-wool, would insert twice a day a plug of that substance, moistened in eau de cologne, or still better, in either of the following solutions: (1) Mastic solution, formed by dissolving a dram of mastic in an ounce and a half of eau de cologne; or (2) Ethereal tincture of tannin, formed by dissolving a dram each of tannin and mastic in an ounce and a half of sulphuric ether. By these means a painful tooth may be often brought into a state in which it will bear stopping. The patient's sensations will warn him against drinking very hot or cold, or sweet or acid fluids, and against exposure to cold draughts of air. Whenever the teeth exhibit a tendency to rapid decay, general tonic treatment is indicated.

2. *Necrosis* is an affection which is characterized by blackness of the tooth and looseness in its socket. It may be caused by violence, accompanied with destruction of the nutrient vessels, or by inflammation of the pulp. If the tooth gives trouble, it must be extracted. Necrosis of the teeth is quite distinct from the very destructive necrosis of the dental alveolar processes and of the jaws generally, which results from the poisonous action of phosphorus fumes, or from the very similar affection which sometimes follows the eruptive fevers. For an account of the singular and terrible disease from which artisans employed in making lucifer-matches suffer, in consequence of their inhaling the fumes of phosphorus (probably in the form of phosphorous acid), which was first noticed in 1839, we may refer to a review of Von Bibra and Geist's exhaustive treatise (in German) on the subject in the *British and Foreign Medico-chirurgical Review* for April, 1848; and to an article on "Phosphorus Workers" in the fifth report of the medical officer of health. Reference is also made to the disease in the article PHOSPHORUS in this work. The necrosis and exfoliation of the alveolar processes and portions of the jaws in children, consequent upon the eruptive fevers, is accompanied by the shedding of the teeth; and according to Mr. Salter, surgeon-dentist to Guy's Hospital, who was the first to describe its true nature, is essentially the same as the necrosis in phosphorus-poisoning, and, like it, is the result of the local application of a specific poison, generated within the individual, to the vascular parts of the teeth. For a description of this remarkable disease, and of the treatment to be adopted, we must refer to Mr. Salter's article on "Exanthematous Jaw-necrosis," in Holmes's *System of Surgery*.

3. *Alveolar abscess* may be defined as a suppuration around the fang or fangs of a tooth, usually carious, accompanied by absorption of the bony walls of the alveolar process, and enlargement of the little sac of pus or matter, which gradually makes its way to the surface, "either along a canal by the side of the fang of the tooth opening at the edge of the gum, or through the gum itself at a point corresponding to the end of the root (or roots) of the tooth implicated. When, however, the fangs are unusually long, or the reflection of the mucous membrane from the gum to the cheek or lip is very superficial, this same discharge may burrow still more outwardly, and find its exit upon the surface of the face."—Salter, *op. cit.*, p. 2. When the discharge bursts, as it most commonly does, through the gum, the alveolar abscess is reduced to its simplest form, and is known as a *gum-boil*. When the discharge takes place in the region of the cheek or chin, the true nature of the case may easily be mistaken by a careless surgeon, who might refer the symptoms to bone-disease. The cause of this affection is either caries or necrosis. In its earliest stage the disease may be cut short by the extraction of the affected tooth, or even by the removal of the stopping, if the tooth is a stopped tooth. If it is desirable to save (for appearance's sake or otherwise) a threatened tooth, the gum should be freely leached, and hot fomentations applied to the swollen part of the face, and the system should be briskly purged. As soon as matter can be detected it should be allowed to escape by a puncture made through the gum—an operation which is followed by immediate relief, and by rapid subsidence of the swelling, although pus continues to be discharged for a considerable time. Indeed, the disease seldom ceases altogether till the offending tooth is removed. When the abscess shows symptoms of pointing on the face, the tooth must be at once extracted, and more serious surgical interference will probably be necessary.

4. *Toothache* is not so much a disease as a symptom of various morbid states of the affected part, which, for convenience, may be classed under this single heading. "Toothache," says Dr. Wood, "offers every possible variety in degree, character, and duration. The pain runs through all the grades which intervene between a slight sensation of uneasiness and unsupportable agony. It may be dull, aching, heavy, sharp, pungent, throbbing, grinding, or lancinating. It may be continued or paroxysmal, remittent or intermittent, and regular or irregular in its recurrence. It may come in

flashes, and as suddenly disappear; or may continue a long time with little variation."—*Practice of Medicine*, 4th ed. vol. i. p. 512. According to the various conditions which give rise to it, toothache may be divided into: (a.) *Inflammatory toothache*, which is almost always dependent upon caries. The inflammation may be seated in the pulp of the tooth, in the nerve-twigs entering the pulp-cavity, or in the periosteum investing its roots, and reflected over the interior of the alveolar cavity. There is generally some external swelling after the pain has continued for some time, and it occasionally extends to the salivary glands. The tooth is at the same time very tender, and any force applied to it aggravates the pain, which is also increased by hot and cold liquids taken into the mouth. When, as in the great majority of these cases, the pain is associated with caries, the best treatment is as follows: "Let the patient have a dose of calomel and colocynth; confine him to spoon diet; let him wash out the mouth with a solution of carbonate of soda in tepid water; let the gum around the tooth, and between it and its neighbors, if tumid and tender, be deeply scarified with a fine lancet; then let the cavity be filled loosely with a little bit of cotton-wool, dipped into the solution of tannin and mastic (for which the formula has been already given); and if the toothache be curable at all, this plan, with a little patience, will be almost sure to succeed. If the pain is very violent, half a grain of powdered acetate of morphia may be taken up with the cotton imbued with the tannin, which should be warmed before it is put into the cavity. As soon as the pain is relieved, the tooth, if of use, should be stopped with gold or amalgam; or if of no use, it should be extracted. It may be added that most of the violent, burning, empirical nostrums, such as creosote, oil of thyme, etc., although they may be of service when introduced in small quantity by a skillful hand into the carious tooth at the right time, can do nothing but mischief when employed indiscriminately, as they are by the vulgar."—Druitt's *Surgeon's Vade-mecum*, 8th ed. p. 458. (b.) *Neuralgic toothache* may occur either in sound or in carious teeth. It may be recognized by its occurrence in paroxysms at more or less regular intervals, and by its being attended with little or no swelling of the external parts. It is very common in the earlier months of pregnancy, and in persons of a general neuralgic tendency, and is often excited by changes in the weather. The treatment is the same as for neuralgia generally. After the bowels have been freely opened, chalybeates and quinine must be given in large doses, and frictions with veratrum or tincture of aconite (both of which are energetic poisons) may be carefully applied to the gum. (c.) *Rheumatic and gouty toothache* may occur in sound or in carious teeth in rheumatic or gouty persons. The constitutional treatment applicable to these diseases must be tried, together with the local applications already noticed.

5. *Falling of the teeth*, due to absorption of the socket, may be regarded as almost an ordinary consequence of old age; but it frequently occurs under the popular name of *scurvy of the gums* in middle age, although very seldom before the 80th year. True, scurvy, gangrene of the mouth, or mercurial inflammation of the gums, may cause the loosening of the teeth at any age; but there are two other conditions which lead to the same result. In one of these affections, the gums swell, and assume a deep red color, and the inflammation appears to be propagated into the alveoli, producing a thickening of the periosteum, and a consequent elevation of the tooth above its ordinary level. By frequently recurring attacks of this inflammation, the tooth is lifted out of its socket, while the gum retreats from the neck, and leaves a portion of the roots exposed. The tooth thus deprived of its support at length falls, after which the gum heals, and the patient is relieved. The remedies indicated are those tending to relieve inflammation of the gum, but they are seldom successful. In the other affection, there is conjoined suppuration of the gums and sockets, and the disease first shows itself by an oozing of pus from behind the edges of the gums when they are pressed. From the absorption of the sockets, and the simultaneous retreat of the gums, the teeth, as in the previous case, at length fall out, if they have not, for the patient's comfort, been previously extracted. Little can be done in the way of treatment in this form of the affection.

6. *Painful and difficult eruption of the wisdom-teeth* requires a few remarks. The cutting of these teeth is often accompanied by distressing symptoms, which may be protracted for months, or even years, unless surgical aid is called in. The difficulties "arise from the position occupied by these teeth, so close to the joint of the lower jaw, where the mucous membrane is reflected from the gums to the cheek and fauces; combined with the very common condition, that the jaw is not sufficiently elongated backward to allow the *dentes sapientie* to range in the horizontal series with the other teeth." This mechanical difficulty not only holds back these teeth in their bony bed, but it often prevents their proper direction of growth. As a consequence of these displacements in the upper jaw, it often happens that when the jaws are brought together, a bit of mucous membrane is nipped and pinched, leading first to ulceration and extreme tenderness, and subsequently to cicatrization and stiffness of the parts. From insufficient room in the lower jaw the crown only partially emerges through the gum, the first cusp coming through it, while the hinder cusps remain covered. This produces a terrible pinching of the mucous membrane over the tooth every time the jaws are brought in contact. Another troublesome symptom, often associated with the painful cutting of a lower wisdom-tooth, is spasmodic but continuous contraction of the masseter muscle, so as to keep the jaws nearly closed, and capable of only slight separation. The most distressing

result, however, is the suppuration that often attends the difficult eruption of the tooth. Even in ordinary cases, when none of these complications are present, there is often a good deal of diffuse and erratic pain in cutting a wisdom-tooth. It is unnecessary to enter into the treatment, which must be left entirely to the surgeon-dentist.

7. *Hemorrhage after extraction of teeth* has occasionally proved fatal, and is not very unfrequently a troublesome and even dangerous complication of the operation. In most of the recorded cases, there has been distinct evidence of the existence of the hemorrhagic diathesis, or, in other words, of a liability to bleeding profusely from the most trivial wounds. No better local treatment can be recommended than that which was suggested by John Hunter nearly a century ago. "In general, it will be sufficient to stuff the socket with lint, or lint dipped in oil of turpentine, and to apply a compress of lint or a piece of cork thicker than the bodies of the adjacent teeth, so that the teeth in the opposite jaw may keep up a pressure." Matico and saturated alcoholic solution of tannin may be equally efficacious as styptics, but are not superior to oil of turpentine. In some cases, the extracted tooth has been successfully replaced as a plug. The internal administration of astringents, such as tannin and oil of turpentine, should be combined with the local treatment.

8. The subject of *tartar on the teeth* has been considered in a separate article.

TEFF. See MEADOW GRASS.

TEFSA, TADLA, or TEDLA, a t. of Morocco, 135 m. n.e. of the city of that name, stands in the fertile, well-peopled district of Tadla, on the banks of the Um-er-Beg. It is one of the oldest towns of the country, and its manufactures of woolen cloths and shawls are important.

TEGÆA, an ancient city of Arcadia, Greece, said to have been founded by Tegeus, son of Lycaon. The inhabitants were noted for their courage, and were subdued by the Spartans only after a prolonged warfare. From Tegea came 3,000 soldiers to the battle of Platæa and disputed the place of honor with the Athenians. They supported the Spartans in the Peloponnesian war, but after the battle of Leuctra joined the league, the formation of which brought on war with Sparta. The city resisted the attack of Lycurgus, but was captured by Machanidas, and afterward retaken by Philopæmen. A good account of the place is given by Pausanias. Its ruins are to be found near the modern town of Tripolizza.

TEGNER, ESAJAS, a Swedish poet of high reputation, was born in 1782 at Kyrkerud, in the Swedish province of Wermland, and educated at the university of Lund, where he took the degree of M.A. in 1802. In 1805 he was appointed sub-librarian to the university, and lecturer on æsthetics. In 1811 the academy prize was awarded to Tegner's poem of *Soea*, or Sweden, which at once raised him to the rank of one of the most popular writers of his country. Prior to the appearance of this successful poem, he had written several spirited war-songs and national odes, which had attracted the favorable notice of the king and government. In 1812 he became professor of Greek, and at the same time was ordained to the pastoral care of the parish of Ståfje. During the next 10 or 12 years of his life, he devoted himself to the prosecution of his clerical duties, and the acquisition of theological learning, with an earnest and unwearying zeal which was scarcely to be expected from his previous indulgence in the pleasures of society, and his natural inclination toward the exhibition of a taste for coarse humor and equivocal puns. During this period, he composed his two famous religious idyls of *Prestvigelsen*, or the "Consecration of a Priest," and *Natvardsbarnen*, or "The Young Communicants," and wrote his *Axel*, a poetic romance, which is regarded by some Swedish critics as even superior to his *Frithiof's Saga*, of which the first cantos appeared in a literary journal, edited by the historian Gejer, under the title of the *Iduna*, and conducted under the auspices of the Gothic society, the leading object of which was to foster national literature, and put down the prevalent taste for the pedantic classical or foreign school of writing. In 1825 Tegner published the closing parts of *Frithiof's Saga*, which rather errs in the opposite direction, and follows too closely the ancient saga on which the tale is founded. But notwithstanding the inharmonious character of the composition, which may be regarded rather as a collection of many ballads and odes in various meters than as a complete epic, the *Frithiof's Saga* became the most popular poem of Sweden, and attracted to its author the admiration and notice both of his fellow-clergy and of the sovereign, as was evinced in 1824 by the clergy of the diocese of Wexio nominating him for the vacant bishopric, and the king at once appointing him to the see. In his place at the diet, as a member of the chamber of the clergy, he made himself conspicuous for his support of ultra-conservative views, in opposition to the extreme liberal doctrines which he had advocated in early life. His speeches in the chamber and on numerous other public occasions have a great reputation in Sweden and Norway, and are devoted to the discussion of questions of education, literature, and finance. In 1839 Tegner was proposed for the archbishopric of Upsala; but in the following year, he was seized with unmistakable symptoms of insanity, which had been strongly manifested in two of his brothers and other members of his family. Although, after a few months' confinement in an asylum, he was able to return to his work, his health soon broke down; and after lingering for many months in a paralytic condition, he died in 1846. His collective

works were edited by his son-in-law, Prof. Böttiger, and published in 6 volumes (Stock, 1848). All his larger and more popular poems have been translated into German, French, and English; the English translations of his *Frithiof* are very numerous, three or four new ones having appeared between 1873 (Spalding's) and 1879. Longfellow's is well known.

TEGUCIGALPA, capital of Honduras, Central America, is situated on the Rio Choluteca, in a table-land 3250 ft. above the sea, and 60 miles from its port of Amapala, on the gulf of Fonseca. Tegucigalpa is the largest and finest city in the state. It has a university, library, ladies' seminary, etc. In the vicinity are gold, silver, copper, iron, and coal mines. Pop. about 12,600.

TEHA'MA, a co. in n. California; drained by the Sacramento river, and by Antelope, Red, Cottonwood, Beaver, and other creeks; traversed by the Southern Pacific Co.'s railroad; about 2988 sq. m.; pop. '90, 9916, chiefly of American birth. The surface between the offshoots of the Sierra Nevada in the e. and the Coast range in the w. is a plain without timber. The soil in the central parts is fertile. The principal productions are corn, barley, wheat, wool, live stock, and wines. Co. seat, Red Bluff.

TEHRAN', or **TEHERAN**, capital of Persia and of the province of Tehran, situated in a barren plain 70 m. s. of the Caspian sea. On the n.e. runs the lofty range of the Elburz mountains, rising in Demavend to a height of 18,000 ft. above sea-level. Until recently the town consisted almost entirely of mud houses, packed within a mud wall 20 ft. high and 4 miles in circumference, but within the last ten years Tehran has been very much modernized, the narrow irregular streets giving place, to a large extent, to wide avenues and boulevards planted with trees, and open squares. The old walls have been replaced by earthen ramparts, which enclose nearly double the territory. A considerable portion of the city, however, is still narrow and dirty. In the midst of the northern quarter lies the great fortified palace of the shah, with gardens, lakes, arsenal, prisons, military school, etc. The city has numerous mosques, a normal school with library, founded in 1850, large modern bazaars, and numerous baths. Its industries are of merely local importance. The population is estimated at about 120,000, which in winter, when the court is at Tehran, is increased to 200,000. Tehran is the most important place in Persia, both as the court residence, and as being the center of European commerce with the east. By the construction of numerous underground water-courses, the formerly arid region surrounding the city has been made inhabitable, and numerous villages and palaces have been erected. In the neighborhood lie, among others, the royal pleasure palaces, Negristan, with beautiful gardens, Kasrkadshar, and Niaveran. To the s. lie the ruins of Rei, the *Rhages* of Scripture, known in the time of Alexander the Great, under the name of *Ragae*, and the birthplace of Harûn-er-Raschid.

TEHUANTEPEC', a river port of the s. of Mexico, in the territory of the same name, and 13 m. above the mouth of the river Tehuantepec, in the bay also of that name. Pop. (est.) 8000. The staple products are salt, cotton fabrics, cochineal, and indigo. Pearl-fishing is carried on, and a purple dye is procured from a shell-fish which abounds in the vicinity.

TEHUANTEPEC' CANAL. See **INTEROCEANIC SHIP CANAL.**

TEHUANTEPEC', ISTHMUS of, that geographical division of Mexico which extends between the gulf of Mexico and the Pacific ocean, in an e. and w. direction, and includes the political divisions Vera Cruz and Oaxaca. It comprises the Atlantic plains, which lie along the foot of the Cordilleras, on the gulf; the central mountainous districts; and the Pacific plains on the west. The basin of the Cootzacalcos, and the contiguous territory, on the e. is a highly fertile alluvial country. This river rises in the Sierras, is navigable 80 m. from its mouth; and is important as offering one of the means for the projected canal connection with the Pacific. The Pacific plains average about 20 m. in width, descending gradually from the mountains. The population of the isthmus, principally Indians and half-breeds, numbers about 62,000; its productions are maize, coffee, cocoa, indigo, cotton, sugar, and tobacco. On the gulf side there are extensive forests of mahogany, cedar, gum, and india-rubber trees. On the western plains are great herds of cattle. The city of Tehuantepec on the river of the same name—which is merely a mountain torrent, thus dignified—is the second town in importance in the state (Oaxaca), and has about 13,000 Indians and half-breed inhabitants, with a few Spaniards. It is situated 11 m. from the Pacific; contains 16 churches, one of which was built by the last Zapoteco cacique in 1530, and possesses manufactures of pottery, cotton, shoes, hats, saddlery, etc. A portion of the isthmus was carefully surveyed by Cortes, who was seeking for an opening to the South sea—the great *desideratum* of the early Spanish navigators to America. Cortes, in fact, was the first to conceive of a method for connecting Asia with western Europe, *via* this isthmus. See **INTEROCEANIC SHIP CANAL.**

TEÏDE. See **MONITOR.**

TE IGITUR, one of the service-books of the Catholic church. It is properly but an extract from the Roman missal, and contains the canon of the mass, and certain other portions of the liturgy which do not vary with the variety of festivals or of the ecclesiastical seasons, but are always the same. It is so called from the first words of the canon, *Te igitur, clementissime Pater*. This service-book, as distinct from the missal, was used, and is still used by bishops, prelates, and other dignitaries; and as the "canon" is the most sacred part of the service, oaths upon the *Te Igitur* were regarded

as especially solemn. The *Te Igitur* appears to have been used as the ordeal "of compurgation."

TEIGNMOUTH, a seaport, market t., and favorite watering-place on the s. coast of Devonshire, situated on the English channel, at the mouth of the Teign, 15 m. s. of Exeter. In front, on the seaside, is the wide, grassy esplanade known as the *Den*, formed of a huge bank of sand, accumulated at the river's mouth, and from this a handsome pier runs out into the sea. The harbor is safe and commodious, though difficult of entrance, the channel of the river being obstructed by a shifting bar of sand. The chief imports are coal and culm; the exports, granite from Dartmoor, and china-clay; there is also a considerable sea and river fishery. Teignmouth is connected with Shaldon, on the other side of the river, by a wooden bridge (completed in 1824) of 34 spans, 1671 ft. in length, with a swing over the main channel for the passage of ships. The climate is mild and salubrious, and the country around beautiful. It is a station on the South Devon railway. Pop. '91, 8292.

TEJADA. See **LERDO DE TEJADA**.

TEKELI (more properly, *Tökely*), **EMERIC**, Count, a celebrated Hungarian patriot, was descended from a noble Lutheran family, and was born at the castle of Kasmark, in the county of Zips, in 1656. His father, count Stephen, had been implicated in the conspiracy of Zriny and Ragotsky to free Hungary from the rule of Austria; and after his death, and the execution of Zriny and others, young Tekeli sought an asylum in Poland, where he had large possessions. After vain endeavors to recover from the emperor his patrimonial estates, he repaired to the court of Abaffi, prince of Transylvania, who put him at the head of an army of 20,000 men, with which, in 1678, he invaded Hungary. Being joined by numbers of the malcontents, he rapidly extended his conquests, made predatory inroads even into Austria, Styria, and Moravia, till Leopold I. was forced (1681) to temporize with the insurgents, and thus gained over a portion of them. But Tekeli, distrusting with good reason the emperor's sincerity, refused to disarm, and being joined by the Transylvanian prince and the Turks, he was declared by the sultan Mohammed IV. (1682) king of upper Hungary, and again recovered most of the country. Tekeli joined Kara Mustapha in his celebrated inroad upon Austria; but after the failure of the expedition many of his followers fell off from him, and his patron, the sultan, being prejudiced by his enemies against him, he was twice imprisoned by the Turks; and during his detention Hungary was wholly overrun by the Austrians, and Transylvania separated from the Turkish alliance. Tekeli, however, was favored by a brilliant though ephemeral change of fortune in 1690, when, at the head of a Turkish force, he burst into Transylvania, routed the combined Austrians and natives repeatedly, and woke up the energies of his partisans in Hungary; but the imperialists, under the markgraf of Baden, routed his allies, the Turks, at Salankemen (Aug. 19, 1691), and under Prince Eugene of Savoy, so completely demolished them at Zenta (Sept. 11, 1697), that they gladly agreed to the peace of Carlovits (Nov. 14, 1697), by which all aid to the Hungarian malcontents was withdrawn. From this time Tekeli lived in retirement in Turkey, at first being munificently entertained by the Turkish government, but afterward so completely neglected that he was forced to adopt the occupation of a vintner. He died at Constantinople in 1705.

TELAUTOGRAPH. A telegraphic system for the fac-simile reproductions of handwriting. This apparatus, which was invented by Elisha Gray, consists of a transmitting and a receiving instrument, each at its station, the two connected by two conducting wires. When the instrument at the transmitting station is written upon in ordinary handwriting, the same is reproduced in fac-simile by a pen, which works automatically on the receiving instrument. Two cords at right angles to each other are connected at the point of the transmitting pencil, which thus give motion to the mechanism as the pencil moves. The motion of a permanently magnetized steel gear-wheel in front of an electro-magnet produces pulsations in the circuit between the machines. The receiving instrument contains an electric motor driven by a local battery, and the pulsations in the circuit control an escapement-wheel driven by the motor which moves the receiving pen so as to make an exact reproduction of the writing on the sending instrument. Both pencils move in unison. The machine has worked satisfactorily over distances of several hundred miles.

TELECTROSCOPE, an apparatus invented by M. Tenlecq, of Andres, France, to reproduce telegraphically at a distance the images obtained in the camera obscura. A camera obscura is arranged with an unpolished glass at the focus, with an arrangement also for autographic telegraphic transmission—the point of the transmitter being made of selenium, which is capable, in a marked degree, of electrical resistance when brought into contact with the light. This point of selenium is made to trace along the unpolished surface of the glass, lightened with variable intensity; the point thus minutely informs the receiver (a tracing-point of black lead joined to a thin plate of iron, and made to vibrate by the current sent through the line which connects with one of the springs holding the selenium) of the light-vibrations; and the lead receiver, in turn, prints these vibrations on a small sheet of paper, ingeniously attached to it. The apparatus possesses much theoretic interest, but has seldom been put to practical use.

TELEPU, *Mydaus meliceps*, a quadruped of the weasel family (*mustelidae*), a native of the mountains of Java, at an elevation of 7,000 ft. and upward; remarkable, like the skunk (q. v.) of America, for the excessive fetor of a volatile secretion formed in glands situated a little within the rectum, the emission of which is its principal means of defense.

TELEGRAPH (Gr. *tele*, far off, and *grapho*, to write) is a general name for any means of conveying intelligence other than by voice or writing. The idea of speed is also implied. It is now used to mean exclusively the transmission of messages over a wire by means of electricity. Alarm-fires (see **BEACON**), the semaphore (q.v.), and the signals (q.v.) used at sea are among the earlier forms of telegraph. But all other agents are now entirely surpassed by the electric telegraph.

The practical application of the scientific laws under which the telegraph operates—in the form of the instrument still, with certain modifications, in general use—is supposed to have been first made by S. F. B. Morse (q.v.) in 1832-35. With the discovery that electric currents could be transmitted instantly over long distances came the idea of employing them for signalling, and in 1774 Bishop Watson made some experiments in discharging leyden jars through 10,600 feet of wire suspended on wooden poles in the neighborhood of London. In the *Scotts Magazine* in 1753 a detailed description of a plan for electric telegraphy is given, and in 1774 a telegraph line was erected at Geneva, Switzerland, which consisted of twenty-four wires connected to pith-ball electroscopes, each representing a letter. The difficulty of using frictional machines, however, prevented the attainment of any practical results in this direction before the discovery of the voltaic cell. In Germany the invention of the telegraph is credited to Sömmering of Munich, whose original apparatus, built about 1811, was exhibited in operation at the Congress of Electricians at Frankfort, Germany, in 1891. Baron Schilling in 1832 exhibited a telegraphic model in Russia in which the letters were represented by the deflections of a single needle. Weber and Gauss modified this plan by using a magnet suspended horizontally, to which a mirror was attached. Steinheil of Munich was the first to notice the important fact that by using the earth as a conductor no return wire is needed. He also invented a code using but two elementary signals in different combinations, and an instrument for recording the characters on a moving strip of paper in the shape of two rows of dots. The telegraph was established as a commercial enterprise in Germany with Steinheil's system, in America with Morse's, and in England with Wheatstone and Cooke's. The first telegraph line in commercial operation was between Paddington and Drayton, in England, in 1835, and was 13 m. in length. This antedated by seven years the Morse line, which was laid between Washington and Baltimore. The printing telegraph was first invented by Alfred Vail, of New Jersey, in 1837, but it was not until 1841 that Wheatstone made his first model of the instrument. In 1845 Mr. C. J. Fleischmann exhibited the Morse apparatus to the emperor of Austria, at Vienna, and with such success that it was adopted by the Austrian government. In 1848 two Americans built a line between Hamburg and Cuxhaven at the mouth of the Elbe, a distance of 90 m., which was operated on the American plan with Morse instruments, and was employed for reporting marine news. The Wheatstone apparatus did not work well except through comparatively short distances, and at a very low rate of speed, and was altogether inferior to the Morse telegraph. The superior efficiency of the latter in working direct through long distances was caused by the application of the relay and local circuit. In Oct., 1851, a convention of deputies from Austria, Prussia, Bavaria, Württemberg, and Saxony met at Vienna to effect a common and uniform telegraph system. By this convention it was decided that the Morse system was practically the best, and this was therefore adopted. In the beginning of Morse's experiments he made use of the fountain pen and other devices for recording the characters; but in the end, the stylus or steel point for embossing these was found to be the most convenient and satisfactory.

The space at our command will not permit us to describe the various steps which led to the introduction of the perfected telegraph. We must be content to furnish a description of the apparatus and methods now in use, and to give some statistics showing the growth of the business and its present extent. In our description of instruments, etc., we shall assume the reader to be familiar with the chief features of electricity (see **GALVANISM**) and of electro-magnetism (see **MAGNETISM**). The apparatus first developed by Prof. Morse depended upon the principle brought out by Prof. Henry, that a piece of iron when wound with wire will exert magnetic attraction as long as a current of electricity sent along the wire is passed through the coil.

The temporary magnetic attraction so produced was used by Prof. Morse to impart a slight movement to a lever placed near the magnet, thereby giving a visible indication each time that the current was sent through the wire at the distant station. Different combinations of charges of current, each one being of only momentary duration, were arranged to represent the letters of the alphabet, and by this means messages were spelled out by short impulses or dots of current over the wire from Washington to Baltimore. This is the foundation of all electric telegraphs. The application of the principle is modified in innumerable ways, for the purposes of permitting the transmission and the reception of the messages to be done in various ways that are convenient for special places and uses. The numerous instruments so employed may be classed under two heads—namely, those which record the signals so that they may be read at any time after the message is received, and those which give only a passing signal, indicated by a sound or a motion, and which therefore require the constant attention of a receiving operator. Among the former are several kinds—namely, those giving a record in arbitrary signs—i.e., in the dots and dashes of the Morse alphabet; those which print the message in ordinary type, such as the modern type-printing instrument, of which the Phelps printer

is the most common, and lastly a class of instruments giving a fac-simile of the message. The last class is not much used, and the instruments which print in type, though used extensively, are confined to main offices where a great many messages are sent rapidly over long lines. We have not space to describe these instruments. See Prescott's *Electricity and the Electric Telegraph*. The greater part of the telegraphing of the world is done by the Morse non-recording instruments, that is the Morse sounder and key, as they are called, and to these we shall therefore devote the greater part of our description, referring the reader to the illustration plate TELEGRAPH INSTRUMENTS.

The Morse Telegraph and Morse Instruments.—The leading principle in the Morse instruments is that by the depression of a key, or by other means, at the sending station an electric circuit is "closed" or completed, and a signal is transmitted along the wire to a distant receiving station, where on its arrival it reproduces the signal by the action of an electro-magnet, or otherwise.

Electrically, the Morse system consists of a battery or other source of electricity and a wire, with the instruments connecting the telegraph stations and returning to the battery. This is done so that a current of electricity is kept in continuous circulation in the wire except when interrupted. A signalling outfit at each office is connected to the wire, and consists of a key for interrupting the current, and thereby producing signals throughout the entire length of the wire, and a receiving instrument or sounder, consisting of an electro-magnet with a responsive lever, which is attracted by the magnet making an audible click when the current passes.

The sounder, fig. 4, consists of a small magnet wound with insulated wire and firmly attached to a base. In front of the poles of the magnet a bar of soft iron, suitable to be attracted by it, is supported by a lever, pivoted at one extremity in such a way that the lever is free to descend and allow the keeper to approach the magnet when attracted by it. The weight of the lever and of the keeper are counterbalanced by a spring which is made adjustable, and is always so adjusted that the keeper is kept away from the magnet by a slight pressure. The motion of the lever, upward and downward, or toward and from the magnet, is limited by adjustable stops. When the keeper and lever are attracted downward by the magnet an audible click is produced by their striking the downward stop. When the keeper is released by the magnet and carried back by the pressure of the spring another click is produced by its striking the upward stop. These clicks are always different in sound, so that the skilled operator has no difficulty in distinguishing an upward from a downward stroke of the lever. The length of wire wound upon the magnet is always proportionate to the length of the line, in order to get the best effect.

The Transmitting Key.—The "key" by which signals are transmitted from the operator at the sending office is shown in fig. 3 in its most improved form. It consists of a lever pivoted near the middle and carrying at one end a knob by which it is manipulated upward and downward by the operator in sending signals, or "writing," as it is sometimes called. Two platinum contacts are fastened respectively to the under side of the lever and to an insulated piece on the upper side of the base. These contacts are exactly opposite to each other, so that they come together every time the key is depressed. The lever is held up and the contacts therefore kept apart, when the key is not depressed by the operator, by a small spiral spring which presses upward under the lever. One end of the line wire is connected to the metallic base from which the current may pass through the pivots to the lever and thence to the small contact point attached to the underside of the lever; and the other end of the line wire is connected to the small insulated piece supporting the lower contact. By this arrangement no current can pass through the line until the key or lever is depressed. Since the terminal of the wire which is fastened to the lower contact is insulated, the current has no means of reaching the other part of the wire. When it is desired to send the current the handle is depressed, and the current generated in the battery, finding a passage between the two contacts, passes from one end of the wire to the other and proceeds upon the line wire to the distant station. Various modifications of this key are in existence, but in all the principle remains the same, that the electric circuit is closed or completed by the depression of a key. The length of time during which the handle is depressed determines the length of time between the upward and downward clicks of the sounder at the other end of the line. Thus if the operator presses down the handle and releases it quickly, the keeper of the sounder will go down and up, immediately indicating the letter "E," while if he presses the key and holds it down a moment before releasing it, there will be a longer interval between the downward and upward clicks of the sounder, and the letter "T" will be produced. In early instruments, before the operators had learned to read the messages by the clicks, the receiving instrument was arranged to make a record of the signals upon a moving strip of paper. For this purpose a pen or pencil was attached to the lever of the sounder, and a strip of paper, kept in motion by clockwork, was arranged to pass under the pen, so that a mark was produced by the pen every time the lever was pulled down by the magnet. If the lever was immediately released a dot was recorded, but if the lever was held down a moment a longer mark called a dash was produced.

Fig. 2 shows such a recording Morse instrument with the letters "H. I. P." written upon the tape. It is of the most improved pattern, being arranged to start and stop the tape automatically. All of the delicate parts are under glass. The signals used at first were

arranged for making the record with a crude instrument of this kind, and while the increasing skill of the operators now enables them to read the signals directly from the clicking of the instrument without looking at the tape, the signals are still spoken of as consisting of so many dots and dashes, as if recorded upon paper.

The Morse Alphabet.—Before going further the details of the alphabet may be given. The only elements which can be combined for making telegraphic signals in the Morse system are the dot, the dash, and the space, and the alphabet is made up of the simplest combinations of these that can be made. The preference of the shortest combinations is given to the letters which are most frequently used. It is stated that Prof. Morse founded his alphabet upon information given him by his brother, a journalist, as to the numerical relation of the letters in the English alphabet. The simplest signal, a dot, being given to "E" and the next simplest, a dash, to "T," those letters occurring most frequently in our language.

Owing to the fact that in some of the early telegraphs used in Europe the space could not be employed as part of any of the signals without causing confusion, it was necessary to rearrange the combinations of dots and dashes, so as to form the whole alphabet with the dot and dash without the use of the space. This alphabet is known as the continental Morse alphabet. It is used throughout Europe and in all submarine telegraphy.

The Battery.—For the generation of power in the electric telegraph, the gravity batteries (see GALVANIC BATTERIES) are chiefly employed in this country. Various forms of the Daniell battery are also used, especially in Europe. The power employed varies with the length of the line, the condition of the wires as regards insulation and the nature of the instruments used. It is now becoming quite common in this country, especially in cities where many lines center, and therefore where considerable quantities of electricity are used for telegraphing, to employ dynamos driven by steam engines for generating the current in place of batteries. In this way in New York galvanic batteries have largely been displaced by dynamo electric generators.

The Circuit.—The mode of joining up two or more stations by means of the line wire is shown in fig. A. It being necessary to furnish a complete circuit or path for the current from the battery over the line and back to the battery, a return connection is required, as mentioned before. But in practice, in telegraph work this return connection is made by simply connecting the instruments at the distant station with the earth, and allowing the current to come back to the battery by this means.

FIG. A.

Assuming S and S₁ to be telegraph stations, P and P₁ are the earth-plates (see subsequent paragraph), B and B₁ are the batteries; *n* and *n'* the sounders, consisting of electro-magnets, with their armatures, while *b k* are the transmitting keys. The connection at the key is always completed by a supplementary switch, when the key is not being used to send a message, in order that the path may be complete for the reception of any message from the other office.

The station at the right in the diagram is now supposed to be sending a message.

Whenever this key is depressed, a current of electricity will pass from the battery, B, along the line wire, around the magnets *n n'*, drawing up the levers and making a click; thence down to the earth-plates, P P₁, and through the earth back to the battery.

Supposing then that the operator desires to send a message along the line wire L L, he depresses his key several times, so as to send a series of dots and dashes corresponding to the letters to be sent to the distant station. These are heard by the receiving operator, who writes down their meaning as fast as received.

The Line.—From the same figure some idea may be gained as to the mode of carrying a wire or series of wires over posts, these posts being carried along the sides of a road or railway. In towns, wires are carried "over-house," or by underground pipes, the wires in the latter case being insulated by means of a gutta-percha or other suitable covering. The subterranean method is being applied to extended lines, especially in Germany, and is found to answer as well as the over-head system, while it avoids many of the casualties to which the latter is liable. In pole and over-house lines, the wires are kept from each other and from contact with the earth by insulators of various kinds. White porcelain and brown stoneware are the chief materials used, and the former, when it is of good quality, well glazed and well burned, is perhaps the most perfect of all insulating materials, and does not deteriorate with age. The fewer the poles are in number on which the wires are suspended, the better is the insulation and the less the cost, but the liability to accident is probably greater. The number of poles used varies from 16 to 30 per mile, and is governed by the number of wires carried, the configuration of the track, and other considerations. On road lines, the number of poles is generally larger than in the case of telegraphs carried alongside railways, the greater levelness and straightness of the latter reducing the number of supports required. The wire chiefly used for inland telegraph purposes is of iron, galvanized, and of No. 8 ($\frac{3}{8}$ in.) gauge. The conductivity of a wire increases in the ratio of the square of its diameter (the resistance decreasing in the inverse ratio), and the advantage of using a thicker wire on the longer lines is thus seen. No. 4 wire is, for this reason, used on some of the longer lines.

The Earth—Earth Currents.—Mention has been made of the "earth," in the preceding description. This is the technical expression used in relation to the fact discovered by Steinheil in 1838, that the earth itself serves the purpose of completing the circuit, and renders the employment of a second or return wire unnecessary. The "earth" may consist of a buried plate of metal connected with the battery or line-wire, and of sufficient surface to afford the necessary contact, with sufficient earth to make a good connection, it being understood that a small quantity of earth does not conduct well. The gas or water pipes of a town form excellent "earths," care being taken that the connection is made with the pipe itself, and not with a branch, where a badly made joint might spoil the connection. Where dissimilar "earths" are in use, as, for instance, a copper plate at one end and an iron pipe at the other, a quasi battery is created, and minute currents pass along the line; these, however, are too weak to be of consequence. The earth, being of great size, offers no sensible resistance to the passage of the current, in the same way that a large wire offers less resistance than a thin one. While this quality of the earth

is one of the most valuable aids to telegraphy (reducing so materially the cost of wire erection), it presents at times those embarrassing interruptions known as *earth currents*. These currents, at all times unwelcome visitors to a telegraph office, are very variable, changing rapidly at times from positive to negative, altering their direction with the hour of the day, and leaving one circuit to appear on another in a manner not explainable. The lines most liable to such disturbances are those running n.e. and s.w.; that is, connecting places separated in a straight line in those directions, and without reference to the actual direction of the wires. The easiest remedy for earth currents, when they are of sufficient strength to affect the lines, is to dispense with the earth connection and revert to the original plan of using two wires. Thus, between places where there are two wires, both may be disconnected from "earth," and used as a complete metallic circuit. Another remedy has been found in extending the circuit by joining to it a further wire, the terminal point of which lies beyond the direction or line in which the earth current is flowing. We must refer to the larger treatises on telegraphy for information regarding lateral induction, velocity of electric discharge, the tests for resistance, insulation, etc., and also for notices of some of the less prominent pieces of apparatus now found in the instrument room of the electrician.

The Relay.—We now proceed to notice several methods by which the transmission of signals is facilitated or accelerated. First among these may be placed the *relay*. In the previous description of the Morse, we have assumed the instrument to be worked directly by the current sent along the line. On long circuits, however, direct working could only be accomplished by great battery power, as, owing to inevitable loss by leakage, a current loses greatly before it reaches its destination. It is found to be a much better arrangement to have the instrument worked by a "local current," derived from a local battery at the receiving station. This is accomplished in the following way: The receiving instrument connected to the line instead of being made heavy enough to give an audible sound by which the signals may be understood, is made extremely light and delicate so that it can be operated by a weak current.

To the lever, which responds and is attracted by the magnetism, is attached a contact point which strikes another stationary contact when the lever is drawn towards the magnet, fig. C, closing a circuit through these extra points in precisely the same way that the usual signalling key is worked. These contacts are connected by short wires with a regular sounder and a small battery. Whenever the delicate lever of the relay is attracted it closes this extra or local circuit and causes the sounder to respond to every signal precisely as if it were connected directly to the main line.

By this device of using a delicate instrument to set another in operation, it is practicable to reproduce faint signals upon a large scale. The use of the "sounder" has greatly increased in this country owing to its cheapness and efficiency. For a description of the type-printing and *fac-simile* instruments, on which great advances have been made of late years, we must refer our readers to the larger treatises on the telegraph and its history.

Duplex-Working.—The fact that two currents may be sent simultaneously (one from each end) has been long recognized by electricians, but the principle of the duplex was revived and patented by Stearns, an American, in 1872. At first the duplex-working was only tried on short circuits of 40 to 60 m.; but it has now become a matter of daily use on every busy circuit, long or short, both in this country and abroad. The principle of the duplex telegraph, which is an apparatus for sending messages simultaneously in different directions over a single wire, may be briefly described as follows: It is accomplished by connecting two complete sets of telegraph instruments to the wire at each end, and so connecting and adjusting one of them that it is only sensitive to the impulses which come *out of the wire*, having traveled over it from the distant end, while the other set, operated by another man, sends signals *into the wire*, which travel to the distant station without producing any effect upon the first set of instruments just mentioned. To accomplish this the current sent on the depression of the key is divided into two parts, one half being carried through one pair of coils in a differentially wound sounder, to the line, and the other half through the other pair of coils to a resistance coil, and thus to earth. The resistance of the latter is made exactly equal to that of the line-wire, and the instrument of the sender being so placed that this divided current presses equally in each direction, this instrument remains unaffected, while the armature at the other end responds to the signal sent. At the same time an operator at the other end is sending a current, which is divided in like manner, and leaves his own instrument unaffected while operating on the armature of the first instrument. The two currents on the line-wire assist or oppose each other in such a way as to affect the equilibrium in the differential sounder, but each operates only on the distant instrument. Duplex-working led to *duplex*, that is, two messages passing over a wire in the same direction at once, and to this has followed quadruplex and multiplex telegraphy. Quadruplex-working was first perfected in 1876 by Prescott, Edison, and Gerritt Smith, but the possibility of its being accomplished was suggested by Stark, of Vienna, in 1855. It was introduced into Britain as a practical branch in 1878, and is now used from London to Liverpool, Dublin, and other towns. An illustration of the value of these additions to the wire power is afforded by a wire from Chicago to Pittsburg, 550 m., which is quadruplexed, and at Pittsburg branches off in two duplex circuits to Baltimore and Philadelphia, giving Chicago duplex communication with these two places. In the same way Middlesborough and

West Hartlepool have been duplexed to London, on separate wires as far as Leeds, and quadruplex on one wire thence to London.

Multiplex Telegraphy and "Phantom" Circuits.—The most original feature of the telegraph section of the Paris exhibition of 1878 was the harmonic telegraph of Haskins and Gray, based on principles laid down by Cromwell Varley in 1870. In one application it occupies a place midway between duplex and multiplex telegraphy, namely, in the "way duplex," or as it was felicitously termed by the late Mr. Orton, the "phantom circuit." A wire may be occupied by the ordinary business of a series of intermediate offices, while there may be superimposed on that a through traffic (which can be duplexed) between the terminal stations. Thus between Chicago and Dubuque, a wire provides for 17 intermediate stations working ordinary Morse sounders, while the harmonic telegraph (the principle of whose action is vibratory currents sent and received by musical forks tuned in unison) works between the terminals. By an extension of this principle we have the multiplex telegraph, each fork taking off at the receiving end those vibrations corresponding to its own tone.

One of the principal instruments used for the purpose of distinguishing different messages which are sent over a wire at the same time is the polarized relay. The object of the instrument is to distinguish between messages sent with a positive current and those sent with a reversed current. Thus two such instruments can be placed in an office, connected to the same wire and adjusted so that one will respond only to the messages sent with the positive current while the other will respond only to those sent with a negative current.

Fig. B.

Fig. C.

The way in which this is arranged will be seen from the figs. B and C. In these N, S is a hard steel permanent magnet whose south end, S, has a slit in which the soft iron armature *a* is pivoted. To this armature a thin aluminium tongue, *b*, is attached, which by making contacts on either side completes either of two local circuits, and operates either of two sounders, according to which side the tongue is attracted to. The coils of the magnet are so connected that a positive current attracts the tongue to one side, while a negative current attracts it to the other.

Automatic Transmitter.—The speed of the ordinary Morse instrument is limited to the rapidity with which the hand of the operator can move the key, so as to preserve the proper spacing between the marks at the receiving instrument. To overcome this we now have an apparatus which trebles, and in some cases quadruples the carrying capacity of a wire, securing, at the same time, mechanical accuracy in the relative size of the dots, dashes, spaces, etc. To effect this, three different instruments are required: First, there is a perforator, by which holes are punched in a paper slip to correspond with the signals required. The operator strikes three disks, the central one producing a central hole, which is of no avail electrically, only carrying forward the paper; the left-hand disk producing two holes, directly opposite to each other, on the sides of this central row, and that on the right producing two holes, placed diagonally to each other. The passage of the electric current is regulated by the position of the outer holes. Those opposite each other admit of a momentary passage of the current through the "transmitter" used in sending the message, while the holes diagonally placed produce a lengthened mark corresponding to the dash. The following diagram represents the word "and," as shown on the punched slip:

As printed at the other end, this reads:

The third portion of this instrument is the "receiver," in which the currents sent by the action of the punched slips in the transmitter are reproduced in the dots and dashes of the Morse code—the printing being, moreover, done with a mathematical accuracy which keying by hand cannot attain. The speed of transmission depends on the length of line and state of the atmosphere; but the movement of the clock-work, both of transmitter and receiver, is capable of adjustment to any speed below 120 words per minute.

This method of transmission is now extensively used on all long lines. By combining the automatic transmission with Bain's principle of producing marks on chemically prepared paper, an American inventor has accomplished still higher speed, the lever action of the sounder or of the pencil recorder being saved.

A system of synchronous multiplex telegraphy invented by Delany has attracted considerable attention, as it provides for the simultaneous transmission of a number of messages either all in the same direction or part in one direction and the remainder in the opposite direction. The apparatus consists of (1) a circular table of alternately insulated and grounded contacts at either end of a telegraph line, (2) a synchronized rotating arm at each end of the line driven by a phonic wheel by means of electric impulses automatically sent out over the main line in either direction, or the failure of the wheel at either end to rotate synchronously with that at the other end, and (3) transmitting and receiving instruments connecting similar contacts at each end of the main line and forming practically separate and independent lines for the simultaneous transmission of despatches over the main line in either direction. The main line is connected at both of its ends to corresponding operating instruments, and transferred from one set of instruments to another so rapidly that the operators cannot realize that the line has been disconnected from their instruments and given to others, because each of them will have the line ready for use even at the highest rate of manipulation. There will therefore be established by the use of a single line as many separate lines as there are transferences of the line from the time it is taken from the first operator and again given back to him. This system has been extended to as many as 72 separate and distinct printing circuits maintained and operated on a single connecting line wire. The best results are obtained from six divisions of the contacts in the circle which gives each operator about 36 contacts with the line per second.

Statistics.—In Great Britain the first public introduction of telegraphy was made in 1846 by the Electric and International Telegraph co. Subsequently the British and Irish Magnetic co. was established, and afterward the United Kingdom co. Besides these companies, there were the London District co., the Universal Private Telegraph co., and a large number of railway companies. In 1868 and 1869, after some agitation of the question, acts were passed transferring the property of the telegraph companies to the post-office, and giving that department a monopoly in the conduct of telegraph business within the kingdom. In 1890 the number of offices belonging to the post-office was 7352, these figures including 1679 railway telegraphic offices. It appears, however, that the railway offices only take in from the public 7 per cent. of the messages sent. The mileage of land lines in Great Britain and Ireland in charge of the postal telegraph department in 1894 was 193,960, and the submarine cables under the same department numbered 118. The latter contained 2875 nautical miles of conductors. Under the government administration the system has been very greatly extended, for which purpose alone the sum of £1,193,684 has been expended in twenty-three years. The rates of toll have also been greatly reduced, and from the standpoint of efficiency this system in Great Britain is second to none in the world. The extent of the growth of its business in twenty-one years may be shown by the fact that during its first year of government control (1870–71) the gross revenue amounted to £801,262, and for 1892 the revenue reached £2,528,423 with the rates of service greatly reduced. From a financial standpoint, however, the British telegraph system has not proved a success. It was acquired by the government at a cost of a little over £10,000,000, and for the first two or three years the results were satisfactory. Since then the expenditures have exceeded the revenues, so that at the close of twenty years (March 31, 1891) a deficit of £4,074,520 had been accumulated against the postal telegraph account. It should be added, however, that there has been a very large extension of the lines and cheapening of the service since it has come under government control.

In 1894 the total length of land lines of the world was 601,142 miles, and the total length of submarine cables with one or more cores, 153,649 nautical miles.

While each kingdom fixes its own internal tariffs and regulations, the rules for the interchange and transmission of telegraph messages between the various countries of the world are regulated by telegraph conventions agreed to at Paris, Vienna, Rome, St. Petersburg, and London (the last named being held in 1879); and all official intimations in connection with international telegraphy are issued from a central bureau in Berne, Switzerland. To the mountain republic the world is indebted, not only for the example of an excellent and cheap internal system, but for the suggestion of this central administration, where all international matters are conducted. In France and Belgium internal telegraph arrangements are complete and cheap; while the United States has for many years held a place far in advance of other countries in the ordinary every-

day use of its great telegraph organizations. Perhaps the most striking instance of telegraph enterprise is that by which the daily newspapers of San Francisco are enabled to give, by means of a line of telegraph carried over the Rocky Mountains (on the line of the Central Pacific and Union Pacific railroads), not only the news from New York, but the parliamentary news from London, the prices of all the continental exchanges, and quotations from Calcutta and China of the previous day.

*These figures are for the Western Union Company's business alone. No others are obtainable.

Since the introduction of the multiplex systems the improvements in telegraphy have been generally in the direction of perfecting the details of the apparatus and methods employed without introducing any radical changes in the principle of the system. One novel method, however, of telegraphing without wires deserves some attention. Induction telegraphy, as this is called, has been operated in two different ways, namely, electrostatic induction and electromagnetic induction. The first system has been employed to communicate between moving trains or between the trains and stations on a railroad. The roofs of the cars being metal, form one condensing surface, and a wire run parallel to the tracks near the roofs of the cars forms the other. Each condensing surface is connected to the earth and are supplied with the necessary instruments and batteries. By changing the charge on one surface a corresponding impulse is induced on the other surface, the impulses being sent and received in Morse characters. Instead of the ordinary sounder a telephone receiver is used. By the use of the electromagnetic induction system it is possible to signal through considerable distance in space. The most notable results with this system were achieved by Mr. W. H. Preece, chief engineer of the British postal telegraph system, who succeeded in telegraphing through distances of three and five miles without intervening wires.

TELEGRAPHY, SUBMARINE.—From the year 1850, when a copper wire insulated with gutta-percha, submerged between Dover and Calais, continued in use for one day, the progress of submarine telegraphy has been as remarkable as that of telegraphy on *terra firma*. The Malta-Alexandria cable was laid in 1861, and continued in use till 1872, when, from repeated breakages in shallow water, its use was discarded. The core consists of a strand of seven copper wires, covered by three layers of gutta-percha; outside of this, a serving of tarred yarn; and, finally, eighteen iron wires, constituting the sheathing. This was the first long cable successfully laid (its total length, in three sections, being 1331 miles); and it was also the first properly tested under water before being laid, and carefully constructed with constant watchfulness as to its electrical and mechanical conditions. This cable was thrown out of use because the chafing it underwent in shallow water made it too expensive in maintenance. So far as construction goes, it corresponds very nearly with Sir James Anderson's typical "successful iron-covered cable." With careful testing and supervision, and with the weight of cable, etc., duly proportioned to the strain, etc., a cable forms a permanent property of much value. A new form of cable, with lead as the conductor, has been suggested. The laying of the first and second Atlantic cables in 1866, after repeated failures, is described at length under ATLANTIC TELEGRAPH. In 1869 a cable 2328 m. long was laid from Brest, France, to the island of St. Pierre, s. of Newfoundland; in 1873, one from Lisbon, Portugal, to Pernambuco, Brazil. In 1874 a third British cable was laid, from Ireland to Newfoundland, and in 1875 a fourth, from Ireland to New Hampshire. In 1877 the task of duplexing a submarine cable was accomplished by Muirhead on the Aden and Bombay cable of the Eastern Telegraph company, and the "artificial line," or balance, has been since applied successfully to other cables, including two crossing the Atlantic. In view of the enormous cost of submarine telegraphy, the attainment of a means by which the carrying capacity of a cable is nearly doubled is of vast importance. In 1877 the Marseilles-Algiers cable, belonging to the French system, was duplexed by M. Ailhaud. The *Journal Télégraphique* gave in 1877 a list of 149 cables belonging to companies, and 420 belonging to government systems, existing at that date. In point of number, Norway

stood first, with 193 cables, but the total length of these was only 233 nautical miles. The total length of the 420 government cables was 4442 nautical miles, of which Britain possessed 49, measuring 1338 miles. The longest of these (excluding cables to the continent) was to Guernsey 70, and to Shetland 63 miles. The company cables (of which 96 per cent. had their administration in London) measured 59,547 nautical miles. The longest cable was that from France to America, 2585 nautical miles, and the largest organization that of the Eastern and Eastern Extension companies, embracing 48 cables of a total length of 21,883 nautical miles, to which, since 1876, several thousand miles have been added in new routes or duplicated cables.

English companies have laid three long ocean cables in the east; and a French organization of capitalists have laid a transatlantic double line. The duplication of the lines of the Eastern telegraph company from England to Bombay was completed in 1878. A similar duplication on the part of the Eastern extension telegraph company has extended the connection from Bombay to Australia by way of Madras, to Penang in the Malay peninsula, and to the East Indian islands. In 1879 the Eastern telegraph company were engaged in laying their cable to the cape of Good Hope. An agreement was made by this company with the British government to have their line down between Durban and Zanzibar by the end of July, 1879, and to have the whole cable laid and in working order by the end of the year. In consideration of an annual subsidy of \$17,500, this company agreed to give priority to government messages, and to transmit them over the cable, which was to have a capacity of fourteen words per minute, at half the rate charged the public. The British government also stipulated for the right to take possession of the wires and offices, or to permit any of the colonies so to do, in the event of the occurrence of a war, rebellion, or any other public necessity, and to retain possession so long as this might be required, on the payment of a reasonable sum in compensation. The Cape cable is covered with a brass wrapping, to protect it against the ravages of the teredos and other injurious insects, except as to those portions laid in the deep sea, where there is no danger from these annoyances. On Nov. 16 the American end of a new French cable, which was manufactured in the workshops of the Siemens Brothers in Charlton, England, was landed at North Eastham, Mass., on Cape Cod, from the steamer *Faraday*. This cable was constructed and submerged at a more rapid rate than any other ever known, the line being completed and messages sent from continent to continent seven months after the concession had been granted to the company by the French government. At about the same time a new cable was put down between Germany and Norway, this being done at the cost of the German government. Prior to that, the only telegraphic communication between Germany and Scandinavia was by way of Denmark. The new cable was a three-wired line, extending from Romøe, an island off the coast of Sleswick, to a point near Arendal. The effect of this enterprise was to throw all telegraphic traffic between Germany and Norway, and the greater part of that with other countries, except Denmark, England, and France, over the new wires, withdrawing it from the Danish lines; this cable was made by Siemens and Halskæe of Berlin. A short cable was laid by Russia across the Caspian sea from cape Gurgian to Krasnovodsk, a distance of 150 miles. This made telegraphic connection between Tjikislar and Asterabad, and messages can be sent by way of Teheran, by the Indo-European line to Tiflis. In 1880, a sixth cable was laid between Europe and America, a seventh and eighth in 1882, and the ninth and tenth in 1884. These last two mentioned belonging to the Commercial or Mackay-Bennett co., start from Penzance, Cornwall, and are connected directly with Cape Ann, Mass., and New York city. Communication is held through these lines with Havre and with Emden in North Germany. In 1882 was completed a submarine line, 3,100 miles in length, between Lima and Vera Cruz in Mexico, crossing the Isthmus of Tehuantepec by a land line of 220 miles; it thus connects the South American Pacific coast with the United States. The employment of subterranean telegraph wires, which has gained much favor on the continent of Europe, has been specially extended in Germany. These were at first only used for short distances, but were found to work so well that they have been laid for considerable lengths, and have entirely answered their purpose. A new method of insulation employed in Philadelphia obviates the difficulties which interfere with the successful working of subterranean wires. In this the material employed is paraffine oil. The wires are first wrapped in cotton, and then as many as fifty or more of them are bound together in a tight cover of netting, the whole being then inclosed in a pipe. The pipe, when laid under-ground, is kept continually filled with the oil under pressure, being supplied from connecting reservoirs. Since 1877 there have been short lines in successful operation on this plan; one of them being laid in 35 ft. of water under the Schuylkill river.

The following table sets forth the entire system of submarine cables of the world in 1896, including those along the shores and in the bays, gulfs, and estuaries of rivers, but excepting those in lakes and the interior watercourses of continents. The list includes all cables operated by private companies, and in addition thereto under the name of each nation is given the list of cables operated by the government of that nation:

| COMPANIES. | Number of Cables. | Length of Cables in Nautical Miles. | COMPANIES. | Number of Cables. | Length of Cables in Nautical Miles. |

The effect of the ocean upon cable signals is such as to make it impossible in cable telegraphy to use currents of strength corresponding to those used on land lines. The causes of this are now perfectly understood, but at the time the first cable was laid they were unknown, and the cable was destroyed because a very strong battery proportionate to the length of the cable was used. On the contrary, it is now found best to use an extremely small battery, and about as much is now used as is required to ring a call bell in a private house. The problem then became to construct an instrument for reading the signals of this weak battery at the other end of the cable. For a long time a delicately suspended magnetic needle or compass was used, and its slight motions were observed by watching a spot of light reflected from the needle upon a screen. But this left no record of the message, and it was necessary for an operator of great skill to give it the closest attention and interpret the signals. The improved apparatus now in use is known as the siphon recorder. See full-page plate, TELEGRAPH INSTRUMENTS. A delicate siphon-shaped tube (fig. 9) hangs from a trough of ink, with its end close to but not touching the moving band of telegraph tape. A fine coil of wire is delicately suspended near a stationary magnet so as to twist slightly when attracting itself to the magnet. The siphon is connected by a thread with the coil, so that the motions of the coil are imparted to it. The apparatus is so delicate, and the moving power of the coil so slight, that the siphon tube is not allowed to touch the paper, on account of the resistance to its motions

when tracing the record which would result from contact with the paper, but the record is made by fine dots of ink which are made to drop from the end of the tube by a slight but constant jarring given to the table on which the whole apparatus stands. The suspended coil is connected with the ocean cable, and every faint signal current sent over the cable enters the coil, throws out delicate lines of force which attract the coil slightly to the magnet, pulls the thread attached to the siphon, and makes a wave in the line traced on the paper. Each different undulation in the tracing signifies a corresponding letter.

The signals employed are according to Wheatstone's arrangement of the European code, in which the dash is replaced by a dot sent with a negative current, or a current of opposite polarity.

All such negative currents would draw the needle, in the case of the recording instrument, to the opposite side of the tape from that to which the positive currents would move it—that is, dots and dashes would be indicated by marks on opposite sides of a line drawn along the centre of the tape. The dots placed above the tape in the figure indicate the composition according to this system of the signals representing the first part of the alphabet. The dotted line represents the way these signals actually appear upon the receiving instrument, and give an idea of the amount of practice required to decipher in these irregular waves the original signals represented directly over them. But by close examination, a definite resemblance can be seen in each case.

The waves are not exaggerated, but are reproduced by photography from a message containing the alphabet, which was transmitted under the ocean specially for the purposes of this illustration.

TELEMACHUS, son of Odysseus (see **ULYSSES**) and Penelope (q. v.), was an infant when his father left home to join in the war against Troy, but during the latter's long absence of about 20 years, grew into manhood. At the instigation and under the guidance of Athene (Minerva), who had assumed the appearance of *Mentès* (commonly known as Mentor, Lat. "the thoughtful one"), king of the Taphians, his father's dearest friend, Telemachus set out in search of his long-lost sire, after having vainly endeavored to eject his mother's troublesome suitors from the house. Having visited Pylos and Sparta, at both of which places he was most hospitably entertained, Telemachus returned home to Ithaca, where he found his father in the guise of a beggar, living with the swineherd Eumæus. After mutual recognition, father and son proceeded to slay the suitors.—In modern times, Telemachus is known chiefly as the hero of Fénelon's (q. v.) romance, *Télémaque*, once very popular as a school-book.

TELEMETRY is the art of measuring the distance to a remote object. For this purpose many forms of telemeter have been invented. They are much used in military operations; the Boulongè telemeter tells the distance of a remote object by the sound coming from it. The artilleryman can by it know the distance which his shell reaches from the noise of the explosion. Gautier's telemeter depends upon the double reflection of a ray of light. In navigation T. is useful in making known the distance of a ship from the shore.

TELEOLOGY, the doctrine of ends, is derived from the Greek *telos*, an end, a word brought into philosophic discussion by Aristotle. The idea of an end entered into the Aristotelian conception of physical science, but more properly into ethical science or morality. All the ancient systems of morality, from Socrates downward, correctly regarded it as a *practical science*; they started with the inquiry, "What is the proper and final end of all human conduct?" and the answer given by each school was the characteristic doctrine of the school. Aristotle answered, "Happiness in a peculiar sense;" the Stoics said, "A regard to the whole universe of being;" the Epicureans, "Pleasure and the absence of pain." John Stuart Mill, in the concluding chapter of his *Logic*, entitled, "The Logic of Practice, or Art; including Morality and Polity," adopts the ancient point of view, and observes that there should be a science of ends, or a reasoned statement of the final purpose of all human action; for this science he suggests the name teleology, remarking that it corresponds to what the Germans call the practical reason. There would be comprehended under it, the art of living or happiness, taste or the beautiful, morality, and politics. See **CIVILIZATION**. The word teleology is applied to the argument from design in proof of the Deity. This is in keeping with Aristotle's employment of the word in physics.

TELEOSAURUS, a genus of fossil crocodiles, the remains of which occur in the oolitic rocks. They are found associated with marine fossils, and the peculiar modification of their skeleton seems to have specially fitted them for an aquatic life.

TELEOSTEL, the order of bony fishes, corresponding very nearly with Cuvier's division of *osseous fishes*, and comprising nearly all the common fishes. Among sub-orders are *malacopteri*, *acanthini*, *acanthopteri*, *plectognathi*, and *lophobranchii* (q. v.).

TELEPATHY (Greek, *tèle*, far off, and *pathein*, to suffer). The affection of one mind by another without communication through the ordinary channels of sensation. Its phenomena are classified in correspondence with the emotions, will, senses and intellect. There are impressions:

1. Emotional; as gladness or gloom.
2. On the motor nerves impelling to action.
3. Interpreted by the sensory centres; as a visible figure (apparition), a sound, touch, taste or smell.

4. Of abstract ideas.

Telepathy has not yet established a claim to be regarded as an exact science. The Society of Psychical Research was founded a few years ago, with headquarters at London, for the purpose of collating psychical facts and scientifically investigating psychical phenomena. It made numerous experiments both upon hypnotized and non-hypnotized patients, and in 1882 sent out circulars inviting records of unusual psychical experiences. Four years later, it published *Phantasms of the Living* a two-volume work, of which Edward Gurney, Frederic W. H. Myers, and Frank Podmon were the editors, embracing all the verified facts large and small, experimental and spontaneous, that had come under its notice, analogies between the experimental and spontaneous, and a few conservative conclusions. Of the last, the most important are (1) that "under particular conditions of excitement—the rationale of which we probably do not understand, though insensibility and the near approach of death are apparently some of the most effectual of these conditions—certain persons appear to have the faculty of communicating to other persons at a distance what is happening to them, often without any intention to do so or any consciousness of doing so on their own parts," and (2) that "certain small experimental results can be produced and that certain impressive spontaneous phenomena are shown to belong to the same class."

TELEPHONE. An instrument for transmitting sounds or speech through a wire by means of electrical vibrations corresponding to the sounds. The first instrument which bore any resemblance to the telephone was constructed in 1860 by Reis, of Frankfort, but it did not embrace the most important principle of the telephone, and would not transmit speech. The successful articulating telephone was invented by Alexander Graham Bell in 1875, and first exhibited at Salem, Mass., and at the Philadelphia Centennial Exhibition.

The crude but operative apparatus of Bell was accompanied by nearly simultaneous inventions of Gray of Chicago, Edison, and others. The instruments were rapidly improved by the same men, and by Berliner, Blake, and a number of others, the best points of each combined, and the apparatus in use now is of very simple construction. The Bell instrument consists of a pear-shaped case containing a bar magnet wound with a coil of fine wire at one end and adjusted in very close proximity to a diaphragm or thin sheet-iron plate placed crosswise at the end of the case. This diaphragm is held in place by a cap screwed to the end of the case, which is hollowed out on the under side, where it bears on the diaphragm, so that the latter is gripped only around its edge, and its center is left free to vibrate towards and from the end of the magnet. Through the center of the cap is a trumpet-shaped opening similar to the mouthpiece of a speaking-tube, for the purpose of collecting the sounds and causing them to set the diaphragm in vibration. Upon the occurrence of any sound near the mouth of the instrument this diaphragm follows the motions of the surrounding air, being set into vibrations which are exactly the same as those constituting the sound. Now, if, when at rest the diaphragm could be set into the same vibrations by any other cause, the air at the mouthpiece would receive the motions or be set into the same vibrations, and the sound would be audibly produced with perfect accuracy, giving every peculiarity of volume, pitch, and quality of the original. This is the first half of the theory of the telephone. If one of these instruments when its diaphragm is set in motion by sounds, can be made to communicate the same motions to a similar instrument by electricity, or otherwise, the same sounds will be reproduced in the other instrument by its diaphragm. This is easily demonstrated by drawing a string tight between the bottoms of two spice-boxes which will serve as diaphragms, the string being passed through holes in the center of the tin and knotted. This is an old device, known as the mechanical or string telephone, and is cheap and effective for short distances. This communication of vibrations of sound over long distances was first accomplished by electricity in 1875 with the Bell electrical telephone described. The coils around the magnets of two such instruments are connected to the terminals of a telegraph wire of any length. When, in obedience to the sound vibrations, the diaphragm of the transmitting telephone approaches its magnet, the latter becomes momentarily strengthened, and an impulse of electricity is generated by induction in the coil. This impulse is transmitted over the wire, passes through the coil around the other magnet, strengthens that magnet, and causes it to attract its diaphragm. When the diaphragm of the transmitting instrument recedes from its magnet, the latter is weakened, and an impulse of electricity in an inverse direction is generated in its coil. This impulse travels over the wire, weakens the receiving magnet, and allows its diaphragm to recede in the same manner. In this way a series of impulses of electricity corresponding exactly in power, rapidity, and shape, or quality, with the sounds generated in the transmitting telephone are sent over the line and reconverted into facsimile sounds at the other instrument.

Although the reproduction of sound with the telephone is perfect in quality, the loss of volume by the time it has reached the ear is very excessive, the loudest as well as the faintest sounds being audible only when the ear is close to the receiving telephone. It is estimated that what reaches the hearer has only one three-millionth of the power of the original sound, and all efforts to improve the telephone in this respect have been unsuccessful. The form of instrument described is known as the Bell receiver, and was the first employed. It served for transmitting as well as receiving. As a transmitter it depends upon its power of generating impulses or waves of current in obedience to the vibration of the air against its diaphragm.

For commercial use, except on a few short lines, the battery system of transmission is now employed. It consists in the use, with the instrument described as a receiver, of a

transmitter in which the necessary impulses are obtained by passing a steady flow or continuous current from a battery through an instrument which throws the current into the proper vibrations, by stopping the current at each interval between impulses. It is made by substituting for the magnet and coil behind the diaphragm a few pieces of carbon between the diaphragm and a solid support. The wires are connected to the support and the diaphragm and the battery current passes through the carbon. When the diaphragm vibrates, the carbon is slightly compressed, its resistance is reduced, and the amount of current passing to the line permitted to increase momentarily. All of the necessary impulses are transmitted in this way, and speech is reproduced with sufficient precision for business purposes. The instrument is known as the Blake transmitter, and is used in connection with the Bell receiver. The transmitter is placed in a square box, with a small magneto hand-generator for ringing the call bell at the central office. The current from the transmitter, instead of being sent directly through the line, is sent through an induction coil, and the amplified current generated therein is sent to the line. The case containing the transmitter and magneto call are now always provided with a sliding-hook upon which the receiving instrument is hung when not held to the ear. The weight of the telephone pulls down this hook and closes an electrical contact whereby all of the apparatus is disconnected from the line, and an alarm bell thrown into connection so that notice may be received when some one is wanted at the telephone.

In the telephone service of cities each instrument is connected by wire to the nearest central office. As each subscriber is liable to call for connection with any one of all the others, it is necessary to so arrange the terminals that every such connection may be accomplished. For this work a device known as the multiple switch-board has been found most successful. It consists of a large frame built in vertical divisions or panels, each panel containing an annunciator for as many of the lines from subscribers as one operator can wait upon, usually about fifty. Below this, but arranged on the same panel or section, and within reach, are a great number of pins connected to all the other subscribers, so that when one of the drops of the annunciator indicates a call from one of the fifty wires in charge of this operator, he can connect that line with the one asked for by attaching one end of a piece of flexible wire to the terminal corresponding to this annunciator drop and to the pin which leads to the other subscriber asked for. Branching connections, for the convenience of the operator, are also made to his board from all of the other wires. And the calls from the lines in other groups are attended to by other operators.

An important branch of the business known as long-distance telephony is now rapidly coming into use. By means of large conductors, improved instruments, and by the use of double lines of wire instead of earth connections, it is made practicable to hold conversations easily over distances of hundreds of miles.

The telephone is of great value for detecting very delicate electric currents, for use in rough testing work on account of its simplicity, and for a great variety of special purposes.

The following table gives the Bell Telephone company's statistics for the U. S. for four years. This company has practically a monopoly of the telephone business in this country.

TELERADIOPHONE, an instrument for reproducing sounds at a distance through the medium of an intermittent ray of light. It is based upon the discovery that if a ray of light falls upon a piece of selenium the resistance of the selenium to the passage of electricity is temporarily decreased. If a battery is connected to a telephone through this selenium, at each flash of the light the strength of the current flowing through the telephone will increase, owing to the decrease of the resistance of the selenium. If the flashes of the ray of light be made rapid, the sounds in the telephone will be correspondingly close together, or a musical note will be produced. The transmitter is arranged to throw the light upon the selenium at each sound or signal. The sounds are thereupon reproduced in the receiver as above described. The apparatus has not as yet advanced beyond the experimental stage. See **SPECTROPHONE**.

TELESCOPE (Gr. *tele-skopos*, far seeing) consists essentially of a lens or mirror, to form, within our reach, an image of a distant object; and a microscope (q.v.), to examine this image in detail. Its invention is ascribed to various individuals living about the end of the 16th c.; but there is no doubt that Galilei (q.v.) was the first to apply it to any purpose other than the gratification of mere curiosity.

The space at our disposal will not allow of our entering into any minute details, so we propose to give: *first*, a general idea of the mode in which a telescope acts, in the course of which we shall incidentally show how the magnifying power and the brightness of the image depend on the dimensions of the various parts of the instrument; *second*, to point out the various causes of imperfection, which in all telescopes are

unavoidable, and how these are reduced to as small an amount as possible; *third*, to mention the most important of the many forms which have been devised, and the processes by which these delicate instruments are practically constructed.

When a lens is employed, as in a camera obscura, to form an image of an object, as AB in fig. 1, the distance of the image from the lens depends on the focal length of

FIG. 1.

the lens, and also on the distance of the object. Practically, with telescopes, the distance of the image from the lens is, on account of the remoteness of the object, the focal length of the lens. Also the image of any point, A , of the object lies in the prolongation of the line joining A with the center, C , of the lens. Join AC , and produce it to a , Ca being made equal to the focal length of the lens, a is the point at which the image

FIG. 2.

of A is formed. Similarly at b the image of B is formed. Thus the image is *inverted*; and, seen from C , the image and the object subtend equal angles, or look equally large. When a concave mirror forms an image, the effect is as in fig. 2, where C is now the center of the sphere of which the mirror is a portion. When the object, AB , is at a great distance, the image, ab , is *inverted*, and is formed half way between C and the mirror. As before, object and image subtend equal angles at C . In order to see these images, the eye must be placed at some such point as E in each of the figures.

So much for the formation *within our reach* of an image of a distant body. We must next show the action of a lens when employed to magnify this image. When an object, as ab in fig. 3, is placed rather nearer to a lens than its focal length, rays which pass from the object through the lens appear to have come, not from the object, but from an enlarged image as $\alpha\beta$, at a greater distance from the lens—but subtending, as before, the same angle at the center, c , of the lens. In practice, the lens is so adjusted as to form the image, $\alpha\beta$, at a distance of about 10 in. from c , in which case the eye sees it most distinctly, and the distance of ab from the lens is then (practically) the focal length of the lens.

FIG. 3.

We now combine the first and third diagrams, and we have the *common astronomical telescope*. The magnifying power is obviously to be measured by the increase in the angle which is subtended by the image $\alpha\beta$ (fig. 4), over that which is subtended by the object, AB . The angle at C is the measure of the apparent size of the object; that at e , of the apparent size of the image. And it is easy to see from the quadrilateral $Caeb$ in the figure that these angles are inversely as the sides Ca and ac . (For instance, if Ca have six times the length of ac , the angle at C will be only one-sixth of that at e .) Hence the magnifying power is to be found by dividing the focal length of the object-lens by that of the eye-lens. In practice, the lenses are so mounted in tubes that their distance may be increased or diminished at pleasure. When the object, AB , comes nearer the observer, its image, ab , is formed *further* from the lens C . Hence, for near objects, the telescope requires

FIG. 4.

to be pulled out. Again, the distance of most distinct vision differs for different people, so that even when AB is at a fixed distance, short-sighted and long-sighted eyes require the eye-lens to be removed from, or advanced to, ab , so that for each eye $\alpha\beta$ may be formed at the distance at which it can be most distinctly seen.

To estimate the relative brightness of the image and object, suppose, for simplicity, all the light which enters the telescope from the object to reach the eye. Then the quantity of light which enters the eye from the image is greater than that which would enter the unaided eye from the object, in the ratio of the aperture of the object-glass, C , to the aperture of the pupil of the eye. But it is spread over a magnified image. If the image be as much larger than the object as the object-glass is larger than the pupil of the eye, the object and image will appear equally bright. Taking the aperture of the pupil as $\frac{1}{10}$ in., the object-lens would require an aperture of 10 in., with a magnifying power of 100 times, in order that brightness should not be lost. Practically, the most formidable difficulty in attaining very high magnifying powers is that due to the enormous size of lenses and mirrors which are required to give the necessary brightness to the enlarged image. It is easy to see that it is impossible to render the final image brighter than the object by any increase of dimensions in the object-lens.

After what we have said about the common astronomical telescope, the reader will have no difficulty, from a combination of figures 2 and 3, in understanding the construction of the Newtonian or Herschelian reflecting telescope.

We proceed to the second part of our proposed scheme of treatment of the subject, viz., the unavoidable imperfections of the telescope, and their reduction to a minimum.

In the first place, then, even with a mirror—where we are not annoyed by the breaking up of white light into its component colors, since the law of reflection (q.v.) is the same for all rays—it is impossible to form a perfectly sharp image of more than *one* definite point at a time. In order to do even this, the mirror must be formed as part of the prolate spheroid produced by the rotation, about its longer axis, of an ellipse (q.v.), one of whose foci is the object-point, the other the image. If the object-point be, like a star, practically at an infinite distance, the requisite form of the mirror is that formed by the rotation of a parabola (q.v.) about its axis. The axis of the mirror must then be directed to the object-point, and all rays from it will, after reflection, pass accurately through the focus. But this is not strictly true for any other object-point in the field of view, although so nearly true that no inconvenience is practically found to result from it. But, if the mirror used be part of a sphere, no point can be found such that rays diverging from it shall all be brought after reflection accurately to one point of the image; and this defect, called *spherical aberration*, increases proportionally to the surface of the mirror; so that by increasing that surface, for the attainment of brightness, we increase proportionally the indistinctness of the image. To give an idea of the delicate manipulation required in the construction of a reflecting telescope, we take the case of a speculum of 4 ft. aperture and 40 ft. focus, as calculated by sir J. Herschel. If this be first ground to a truly spherical form, it must have a radius of 80 ft., as we have seen above. Now, such a mirror will give a very indistinct image, even under the most favorable circumstances; yet to grind it to the parabolic form, which is practically perfect, leaving the middle untouched, and grinding more and more away from its surface as we proceed outward to the edges, even at the edges we have to remove a film of metal of only the $\frac{1}{1000}$ part of an inch, somewhere about the $\frac{1}{100}$ part of the thickness of the paper on which this is printed!

Lenses, whether the object-lens or the eye-lens, have this defect also; but, as a rule, the spherical aberration in lenses is almost negligible compared with *chromatic aberration*, which arises from the different refrangibilities (see REFRACTION) of the various colored rays; and leads to the formation, by a lens, of a separate image of a bright object for each colored ray. The remedy consists in *achromatizing* (see ACHROMATISM, REFRACTION) the lens—i.e., forming it of two or more lenses of different kinds of glass—so that the colors, separated by one, shall be reunited by the others. With a double achromatic lens, in which a convex lens of crown glass is united to a concave of flint-glass, the focal lengths of the separate lenses can be easily adjusted so as to bring, when in combination, any two assigned rays of the spectrum (q.v.) simultaneously to a focus; and, by a judicious selection of these two rays, we may reduce the consequences of irrationality of dispersion (see REFRACTION) to a minimum. But this is not all. To construct a lens of a given material which shall have a given focal length, is an *indeterminate* problem; we may assign the curvature of either surface at pleasure, and then that of the other is definite, and can be calculated. Thus, the achromatism of a double-lens can be secured in an infinite variety of ways, and we may impose further conditions; i.e., that the curvatures of the convex and concave surfaces shall be adjusted so as to destroy as far as possible the spherical aberration. Other imperfections, such as those due to diffraction (q.v.), etc., cannot be here more than alluded to, as they do not admit, within any reasonable limits, of being popularly explained. Nor can we enter upon questions connected with the correction of chromatic and spherical aberrations in eye-pieces, which is effected by the combination of two or more lenses (generally of the *same* material) placed at a certain distance from each other. We may only mention that the defect (for terrestrial purposes) of the common astronomical telescope, the inversion of the image, is overcome by combining two such telescopes, the smaller to examine the image formed by the larger, and therefore to reinvert it. This practically comes to constructing the eye-piece of three lenses at a distance from each other; though, for greater distinctness, four are usually employed.

In the earliest, or Galilean, telescope, the eye-lens is concave; a construction only

now used in opera-glasses. It has far less chromatic and spherical aberration than the common astronomical telescope, and is shorter, since the distance between the lenses is the *difference*, not the *sum* of their focal lengths; but it has a very serious defect in the smallness of its field of view. This can only be enlarged, as in opera-glasses, by making the diameter of the object-lens disproportionately great.

Before the discovery of the possibility of forming an achromatic lens, Huygens, Cassini, and others, had endeavored, by enormously increasing the focal length of the object-glass of the common astronomical telescope in proportion to its diameter, to get rid as far as possible of chromatic aberration. This was called the *aërial* telescope, as the object and eye-lenses were mounted separately on stands; the tube (which would have been 100, 200, or even 600 ft. long) being dispensed with. Valuable work was done with some of these telescopes, of 125 ft. focus, but the longer ones proved unmanageable. The principle involved in these constructions is, practically, the throwing the magnifying power more on the object-lens than on the eye-lens; as the image formed by the former was still so imperfect as not to bear much additional magnification; although achromatic eye-pieces could even then be made with one kind of glass. The great step required for shortening the unwieldy instrument was therefore the perfecting of the object-lens. We have already seen how this was effected. Various very ingenious improvements on achromatic combinations, even yet (we should be inclined to think) worthy the consideration of opticians, were devised by Dr. Blair. He obtained in solutions of mercury or antimony in hydrochloric acid, media, in which, while much more refractive and more dispersive than crown-glass, no irrationality of dispersion as compared with crown-glass could be detected. With these fluid lenses he was enabled to give the telescope an aperture of $\frac{1}{2}$ of its focal length without a trace of residual color. The *diolytic* telescope, invented in 1828 by Mr. Rodger, and since made by Plössl, seems to promise very well. Its object is to obtain a large aperture for the telescope with a flint-lens (the obtaining of which, in large and perfect disks, is the great difficulty) of moderate size. In this telescope the object-lens is single, and of crown-glass; having, of course, all the defects of the single lens. These are corrected, at some distance in the cone of converging rays, by the interposition of a combination of a pair of much smaller lenses, whose focal lengths are equal for red rays; the first being a convex lens of crown, the second a concave of flint glass. The adjustments of this instrument for exact correction are, a motion of the pair of lenses to or from the object-lens, to correct chromatic aberration; and a change of the distance between the two smaller lenses, to correct spherical aberration.

Chromatic being so much more serious than spherical aberration, it is not to be wondered at that the idea of substituting an object-mirror, in which the former is absent, for an object-lens, was early suggested. The first practicable scheme for the purpose seems to have been that of Gregory; in which, however, two mirrors are employed. In the skillful hands of Short, this instrument completely superseded the ordinary astronomical telescope. Its chief defects are, the great loss of light by two direct reflections, and the increase of the spherical aberration by the fact that both mirrors are concave. The first defect is incurable, the second was partially overcome by Cassegrain's plan of using a small *convex* mirror for the second reflection. To Newton is due the simple idea of using the combination of a single curved mirror with a plane mirror and an eye-piece; a construction differing only in slight particulars from that now universally adopted for reflecting instruments. Newton constructed several such telescopes with his own hands, some of which are still preserved, as in the apartments of the royal society at Burlington House.

The process of Liebig for depositing on glass an exceedingly thin film of silver, which, by careful polishing, can be rendered more highly reflective than any other material, has been taken advantage of by Steinheil in the construction of large specula. This is an immense step, since any disk of glass will do, its optical properties not being employed; while, if it be once brought to a true parabolic figure, the silvering may be renewed as often as may be required. One of the great difficulties in the construction and working of large reflectors has hitherto been the casting and annealing of metallic masses of a few tons' weight. This, in the silvered specula, is entirely avoided. We cannot here enter into a description of the processes, often extremely ingenious, which have been devised for the grinding, figuring, and polishing of lenses and specula. Nearly all the recent telescopes are refractors; a notable one is that in the Lick observatory, Cal., having an aperture of 36 in.; among the other large ones are that of Poltava, Russia, lately made by the Clarks of Cambridge, Mass., object glass 76 centimetres; Nice, also 76; Paris, 73.5; Vienna, 68.5; Washington, 66; and the McCormick telescope, 66. A reflecting telescope of importance is that of Common, erected at Ealing, Eng.; it has a silver-on-glass reflector of $37\frac{1}{2}$ in. diam., and has proved to be a very powerful instrument. The largest refracting telescope in the world was presented by Charles T. Yerkes to the Chicago university. The lens is 40 inches, the steel tube 64 ft. long, and the column on which it rests 43 feet in height. The dome in which it stands is 90 feet in diameter, and 60 ft. high (see illustration). The dome revolves by machinery to keep pace with the motion of the earth, so that the telescope may point to any particular star all night. The floor may be raised and lowered so as to keep the observer's eye level with the glass. All the adjustments are made automatically by electricity.

TELESEME, an instrument for automatically telegraphing either of a number of words that are printed on its dial, by merely setting the pointer to the required word. An important feature is that, after being set, it remains locked and does not transmit its signals until the wire is entirely free from other messages. This is called the latent signal, and was invented by Dr. F. Benedict Herzog.

TELETHERMOMETER or **TELEMETER**. See **TELEMETRY**.

TELFAIR, a co. in s. Georgia, drained and bounded by the Ocmulgee and Little Ocmulgee rivers; traversed by the Savannah, Americus, and Montgomery, and the Southern railroads; 491 sq. m.; pop. '90, 5477. Co. seat, McRae.

TELFORD, THOMAS, an eminent engineer, was b. in the parish of Westerkirk, in Eskdale, Dumfriesshire, Aug. 9, 1757. His father was a shepherd; and during the intervals of his attendance at school, young Telford followed the same occupation, diligently employing his leisure moments in the perusal of whatever books were within his reach. At the age of 14, he adopted the trade of a stone-mason; and long years afterward, when he had attained the summit of his profession, he confessed the advantages which he derived during this period from "the necessity of making himself acquainted with every detail in the procuring, preparing, and employing of every kind of material, whether it be the produce of the forest, the quarry, or the forge." In 1780 he removed to Edinburgh, and in 1783, he repaired to London, obtaining employment under sir William Chambers, who was then engaged on his chief work, the erection of Somerset house. Telford's merits attracted the notice of his employer, and he was appointed in 1784 to superintend the erection of the resident commissioner's house at Portsmouth dockyard, a work which lasted over three years, and afforded Telford the opportunity, of which he fully availed himself, of mastering the details of construction of docks, wharf-walls, etc. In 1787, he was appointed surveyor of public works for Shropshire; and his two bridges over the Severn at Montford (3½ m. w.n.w. of Shrewsbury) and Buildwas (1½ m. w. of Coalbrook Dale), a large number of minor bridges, and other county works, testified to the genius and industry of the rising engineer, and gained for him the planning and superintendence of the projected Ellesmere canal, 103 m. in length, to connect the navigation of the Severn, Dee, and Mersey—a work which occupied 10 years (1795–1805), and greatly added to the already eminent reputation of Telford. In 1790 he was appointed by the British fishery society to inspect the harbors at their various stations, and in 1801 he received a commission from government to report on the state of Scotland, and on the desirable public works for that country. As a consequence, the plan of a canal from Inverness to Fort-William was revived, and its planning and construction intrusted to Telford (see **CALEDONIAN CANAL**). In the same capacity of engineer to the parliamentary commission of roads and bridges for Scotland, he executed more than 1000 m. of road in the Highlands, Lanarkshire, and Dumfriesshire (see **ROADS**), and erected about 1200 bridges, besides churches, manse, harbors, etc. In 1808, and again in 1813, he was invited to Sweden, to report on the projected scheme for connecting lake Wener with the Baltic, and superintended the construction of the Gotha canal, by which this was effected; receiving on his departure numerous and valuable marks of the royal approbation. His next great work was the construction of the road from London to Holyhead, including the erection of numerous bridges—among others, of the Menai *suspension bridge* (q.v.)—and the last was the execution of the St. Katharine's docks in London, a work of remarkable merit. His other works are far too many to enumerate. We can only afford to state that, of bridges, the Conway (q.v.), the Broomielaw at Glasgow, the Dean in Edinburgh, the Over at Gloucester (an innovation on the ordinary form); of canals, the Glasgow and Paisley, the Macclesfield, the Birmingham and Liverpool junction, the Gloucester and Berkeley, the Weaver system, the great tunnel (1½ m. long) on the Trent and Mersey; of harbors, Peterhead, Banff, Fraserburgh, Fortrose, Cullen, and Kirkwall—were planned by this indefatigable genius, and wholly or partially erected under his superintendence. He was much employed by parliament to report on all public engineering schemes or works of importance, and was also occasionally consulted by the Russian government. For the last few years of his life, he retired from the active duties of his profession, employed himself in collecting and arranging materials for a complete history of his various works, and had the greater portion of the MSS. ready when he was seized with a severe bilious attack, and died at Abingdon street, Westminster, Sept. 2, 1834. His life, entitled *The Life of Thomas Telford, Civil Engineer, written by himself*, was published in 1838, in 1 vol. 4to, accompanied with a companion volume of plates.

TELL, a district in the extreme n.w. of Africa, stretches along the shores of the Mediterranean, and comprehends the corn-growing tracts extending s. from the Mediterranean to the Atlas mountains, and from w. to e. through Morocco, Algeria, and Tunis. The Tell is noticed under the articles Africa and Sahara (q.v.).

TELL, WILLIAM, was, according to Swiss tradition, a patriot who, in the 14th c., rescued his native district from the tyranny of the house of Austria. His story has been variously told, but that version which has found the widest currency is the following. In the beginning of the 14th c., Albert I. of Austria was striving to annex the three Waldstädte, Uri, Schwyz, and Unterwalden, to his family estates. Hermann Gessler, his bailiff (or *Landvogt*), lived at the castle of Küssnacht, and perpetrated on the people of the dis-

friest the most atrocious cruelties. A league was formed of the principal men of the Waldstätte to resist the Austrian pretensions, and to it belonged Walter Fürst, and William Tell, his son-in-law. Among other acts of tyranny, Gessler placed the ducal hat of Austria on the top of a long pole, erected in the market-place of Altorf, and gave orders that no one should pass without uncovering his head. Tell and his little boy one day took no notice of the hat, and were at once dragged before Gessler. He, hearing that Tell enjoyed great reputation as a cross-bowman, resolved to make his skill a means of punishing him. He was ordered to shoot an apple from his son's head, and told that if he missed it, he should die. To the amazement of all present, he hit the apple without injuring the child. But this did not satisfy Gessler. Turning to Tell, he asked him what he meant to have done with a second arrow he had in his girdle. "To have shot you if it had slain my son," was the reply. Tell was then seized, bound, and thrown into a boat on the lake of Lucerne, to be taken with Gessler and his men to the castle of Küssnacht. A sudden Alpine storm sprung up. Tell was the only man on board who knew the shore, and could manage a boat in such weather. He was allowed to take the helm, and he soon ran her toward a rocky ledge; he there seized his bow and arrows, sprang on shore, and pushed the vessel back into the water. The storm, however, abated, and Gessler and his party landed. Tell lay in wait for them in a rocky defile, and as they passed, he shot Gessler through the heart. This befell in 1307, and was followed by the great Swiss war with Austria—the first of a series which lasted till 1499—in which, however, Tell took no prominent part. Tell was drowned, it is added, in 1350, in attempting to save a friend during a great flood of the river Schächen.

There is evidence that, in 1387, a religious service was instituted to commemorate the act of Tell at the place where he lived; and that, in the following year, Tell's chapel was built on the spot where the boat was said to have landed. Russ and Etterlin, chroniclers who lived toward the end of the 15th c., told his story as true history. Tschudi, who wrote in the first part of the 16th c., repeated it in the form in which it is now familiar to us, and in which it was adopted by Schiller, in his well-known drama. So early as the end of the 16th c., however, doubts were expressed of its authenticity. Guilmann, who wrote a book, *De Rebus Helveticis*, called in question the very existence of Tell. What, he asks, has become of his family and relatives? Why was he not spoken of by his contemporaries? Grasser, the author of a Swiss *Heldenbuch*, pointed out a striking resemblance between Tell and Toke, the hero of an old Scandinavian fable, recorded by Saxo Grammaticus. From that period, incredulity became general, and several books were published to show that the story was legendary. One of these, *Guillaume Tell; fable danoise*, was burned by the public hangman at Uri, and then a patriotic feeling was manifested on the subject, which, it is believed, made Swiss writers, including J. von Müller the historian, cautious in expressing farther doubt. Voltaire, in speaking of Tell, makes the remark, that "*l'histoire de la pomme est bien suspecte*," and asserts that no part of the tale had a foundation in fact. His opinion became known all over Europe; and since then, a whole library has been published on the story of Tell, in Switzerland, Germany, Denmark, and France. The most important works, however, bearing on the question, are (1) Ideler's work, *Die Sage vom Scheusse des Tell*, published at Berlin in 1826, in which it is shown that the incident of the apple is purely legendary; (2) an edition of Russ's chronicle, edited in 1834, by M. Schneller of Lucerne, in which it is proved that serious disparities exist between the different versions of the story as told by the Swiss chroniclers; and (3) a work containing a series of documents relating to early Swiss history, published in 1835 by M. Kopp, also of Lucerne, in which it is as satisfactorily shown that, although a continuous series of charters exist relative to the bailiffs of Küssnacht in the 14th c., there is no Gessler among them. Tell is nowhere mentioned in contemporary records; but it need not, therefore, be inferred that an obscure peasant did not exist of the name, who shot an Austrian bailiff on the banks of the lake of Lucerne, who by this act caused a revolt, and who lost his life in attempting to save that of a friend. If such incidents really occurred—and from the early foundation of Tell's chapel, and other facts connected with it, we must presume they did—it would be easy to explain how they became connected with the old fable of the tyrant, the bowman, and the apple.—Ample information on the Tell controversy will be found in Hisely's *Recherches* (1843); and Vischer's *Die Sage von der Befreiung der Waldstätte* (1867).

TELLER, HENRY M., b. Allegany co., N. Y., 1830; graduated at Allegany univ.; was admitted to the bar, 1858, and removed to Ill. He settled in Colorado, 1861, and was chosen the first U. S. senator from the new state, 1876. In the senate he was noted as an advocate of the unlimited coinage of silver. He was sec. of the interior, 1882-85, under Pres. Arthur; U. S. senator from Colorado, 1885 and 1891.

TELLEZ, GABRIEL, better known by his literary pseudonym of *Tirso de Molina*, a Spanish dramatist of great reputation, was b. at Madrid in 1585, became a monk in 1620, and died in 1648, prior of the order to which he belonged. Tellez was a friend and pupil of Lope de Vega, whom he almost rivaled in facility of execution. In the preface to his *Cigarrales de Toledo* (1621), a collection of novels and comedies, he reckons the number of the latter composed by him at 300; of which, however, only 68 have come down to us. Besides these, he wrote several interludes, a great number of *Autos Sacramentales*, an *Acto de Contrición en Verso*, and a *Genealogía de los Condes de Sástago* (Mad. 1640). Tellez ranks next to Calderon and Lope de Vega as a dramatist. Although he generously affected to consider himself only a follower of the latter, he is really one

of the most decisively original geniuses of his country, and imitated Lope in nothing except in cultivating the same national spirit in literature. His plays, deficient in artistic conception, are full of dramatic vitality. The "situations" are numerous and captivating, the delineation of character fresh, piquant and vigorous; the wit abundant, and the language richly poetical.—The best edition of Teller's works is that of Don Juan Eugenio Hartzenbusch, in the *Teatro Escogido* (12 vols., Madrid, 1839-42).

TELLICHERY, a sea-port t. and military station of British India, in the district of Malabar, Madras. It is situated on the open sea, in a beautiful and fertile district, the low lands producing two, and in some cases three, crops of rice in the year. Spices and sandal-wood are exported. Pop. '91, 27,196.

TELLINIDÆ, a family of lamellibranchiate mollusks; having the mantle widely open in front; the foot tongue-shaped; the siphons separate, long, and slender; the shell usually equivalve and shutting close, the hinge toothed. The species are very numerous, and are found in almost all seas, mostly living in sand or sandy mud, some of them at a considerable depth. The fossil species are also numerous, and are found in the more recent formations. The genus *donax* belongs to this family.

TELLURIUM (symb. *Te*, equiv. 64—new system, 125—spec. grav. 6.24) is a chemical element, which some authorities place among the metals, and others among the non-metallic bodies or metalloids. Although in its outward characters it closely resembles the metals, its close analogies with sulphur and selenium indicate that its true place is among the metalloids. It possesses a high metallic lustre, and resembles bismuth in color; it fuses at about 932° F. (500° C.), and at a higher temperature is converted into a yellow vapor; it is a bad conductor of heat and electricity. When strongly heated in the air it burns with a blue flame, and gives off white fumes of tellurium dioxide. Like sulphur and selenium, it is soluble in cold oil of vitriol, to which it gives a fine purple-red color, and on dilution it is precipitated unchanged; and in these respects differs from all metals. In nitric acid it dissolves with oxidation.

Tellurium forms two compounds with oxygen, viz., *tellurium dioxide*, TeO_2 , and *tellurium trioxide*, TeO_3 . These have corresponding hydrates; *tellurous acid*, H_2TeO_3 , and *telluric acid*, H_2TeO_4 , which are parallel with sulphurous and sulphuric acids. *Tellurous acid* exhibits very slight acid properties, and in the anhydrous state it even combines with acids, and acts the part of a weak base. These salts have a metallic taste, and are said to act powerfully as emetics. The *telluric acid* has only a feeble affinity for bases, but it forms salts, which contain 1, 2, and 4 molecules of the acid to each molecule of base. Tellurium unites with hydrogen to form tellureted hydrogen, TeH_2 , which is a gaseous body, analogous to hydrogen sulphide, and precipitates most of the metals from their solutions in the form of tellurides, which have a close analogy with the corresponding sulphides.

In experimenting upon the action of the salts of tellurium, it has been found that they possess the power of forming, in the body of a healthy person, compounds which impart to the breath, to the perspiration, and to the gases generated in the intestinal canal, a disgusting fetor, which makes him a nuisance to every one he approaches.

Tellurium is a rare substance, found chiefly in Transylvania, but recently discovered in Hungary, in North America, and in the Altai silver mines. It sometimes occurs native, but more commonly as a telluride of gold, lead, or silver. For the method of extracting it, we must refer to any of the larger works on chemistry, and especially to the *Lehrbuch* of Berzelius. It was discovered in 1782 by Müller von Reichenstein, but it was not till 1798 that its properties were accurately studied by Klaproth. The word tellurium is derived from the Latin *tellus*, the earth.

TELPERAGE, a system of aerial transportation devised by Prof. Fleeming Jenkin, and designed primarily for the transportation of freight. A light wire rope or steel rod serves as the conducting rail, and is strung between poles at such a height that the carriages or buckets, called "skips," cannot possibly touch the ground in their passage. A train is composed of several carriages headed by an electro-motor, in a separate frame. Several systems are in use. In that of Ayrton and Perry, self-governing motors, weighing only 96 lbs., are used. Saddles curved in a vertical plane are placed at the extremities of the cross-arms of the supporting posts, and to these the wires or cables are attached. By one method of construction, called the "series" system, the line is divided into successive sections, and the train as it moves by, breaks the electric connection between them, this being restored automatically as the train passes on. Experiments with a line at Weston, England, arranged on the multiple arc system, led to the conclusion that, working 20 hours a day, a train could transport 1850 tons a m. It was found that the carriages ran smoothly, that the grip of the locomotive was entirely satisfactory, and that there was no difficulty in insulation even with high-tension currents. It will be seen that for the transportation of freight, of ores, coal, etc., telpherage affords a cheap and comparatively easy method.

TEMBU (Abatembu, or Tambookie) is the name of an important tribe of Kaffirs, occupying the region e. of the present boundary of the Cape Colony, where it forms the eastern limit of the district of Queenstown, formed by sir Harry Smith in 1849-50, a rather elevated plateau, from which flow the head-waters of the Kéi, Bashee, Tsomo, and other important rivers. They number about 90,000 souls.

TEMES, a co. in s.e. Hungary, in the trans-Tibiscan circle; 2741 sq. m.; pop. '90, 434,529. It is drained by the Berzava, Temes, Krassó, and Nera rivers. The soil is very fertile, producing wheat, corn, hemp, flax, fruit, cotton, and grapes, from which much wine is made. The silkworm is raised, and great numbers of cattle. Capital, Temesvár.

TEMESVÁR, a city in Hungary, the seat of a Roman Catholic and Greek bishop, situated in a plain on the Bega canal, 188 miles s.e. of Budapest. The town is strongly fortified, and has handsome streets and large public squares, two cathedrals, an ancient castle, built by Hunyady in 1442, a palace of the Greek Catholic bishop, an armory, barracks, and a theater. Temesvár has important manufactories of cloth, paper, leather, wool, soda, oil, machinery, etc., royal tobacco works and a large brewery. There is also important trade in grain and wood. Temesvár was founded in the 13th century, was afterwards a strong fortress, and played a prominent part in the Turkish wars. It has often been besieged, most recently in 1849, when it was bombarded 107 days by the Hungarian insurgents, and partly destroyed, when it was relieved by Marshal Haynau. Pop. (a mixture of Germans, Magyars, and Roumanians), '90, 39,884.

TEMISCOUATA, a co. in s.e. Quebec, Canada, bordered n. by the St. Lawrence river, and s. by New Brunswick and Maine; 1770 sq. m.; pop. '91, 25,698. The surface is mountainous. Co. seat, Isle Vert.

TEMPÉ, a narrow valley or gorge, about 6 m. long, in the n.e. of Thessaly, between Olympus (q.v.) and Ossa (q.v.), through which flows the river Peneus. The classic poets (none of whom, curious to say, appear to have ever seen the glen) praise it for its matchless beauty, and hence the name with them became a synonym for any lovely vale. In point of fact, however, the scenery of Tempé is characterized by wild grandeur rather than by soft sylvan charms.

TEMPERA, in painting, the same as *distemper* (q.v.).

TEMPERAMENT is a term which has been employed in physiology ever since the time of Galen, to designate the certain physical and mental characteristics presented by different individuals. Dr. Todd, in his article on this subject in the *Cyclopædia of Anatomy and Physiology*, observes that "the temperaments the existence of which seems most consistent with observation, are those admitted by Cullen, namely, the *sanguineous* and the *melancholic*, the *phlegmatic* being a degree or modification of the sanguineous, and the *choleric* of the melancholic."

Individuals of the *sanguineous* or *sanguine* temperament are such, according to Cullen, as have the quantity of fluids in the body large in proportion to the solids; the habit of body soft and plump; the skin smooth, white, and readily sweating on exercise; the hair soft, and generally pale, passing from thence to a red tint; the complexion ruddy; the eyes blue; the bodily strength moderate; and the mind sensible, irritable, cheerful, and unsteady. In persons of the *melancholic* temperament, the habit of the body is somewhat hard and meager; the skin and complexion coarse, and of a dun color; the hair hard, curly, and black; the strength considerable; the mind slow, disposed to gravity, caution, and timidity, but tenacious and steady.

Some writers recognize a *nervous* temperament, in which the predominating characteristic is a great excitability of the nervous system, and an undue predominance of the emotional impulses. This temperament is always associated with the sanguineous or the melancholic. In both sexes, the characteristics of the temperaments are far less manifest in old age than in earlier life. If it be admitted, as Dr. Todd believes, that a constant connection exists between color and temperament, it obviously follows that the nature of the temperament is determined by certain peculiarities in the physical condition of the organism. The different temperaments often merge so gradually into one another that it is in many cases difficult to decide positively to which variety any special case belongs.

TEMPERAMENT, in music, a system of compromise in keyed instruments for the avoidance of the necessity presupposed by the strict relation of musical intervals of having a separate row of keys corresponding to each tonic. Taking C as keynote, the ratios of the notes of the diatonic scale, as derived from the number of vibrations in a given time of a string sounding that note (see *MUSIC*), are:

| | | | | | | | |
|----|----|----|----|----|----|----|----|
| C | D | E | F | G | A | B | C |
| 24 | 27 | 30 | 32 | 36 | 40 | 45 | 48 |

The intervals between these notes are by no means equal, and may be thus expressed in numbers by logarithms:

| | | | | | | | |
|----|----|----|----|----|----|----|---|
| C | D | E | F | G | A | B | C |
| 51 | 46 | 28 | 51 | 46 | 51 | 28 | |

We have here three species of intervals, of which those represented by 51 are called major tones; those by 46, minor tones; and the smaller intervals represented by 28, semitones. These intervals will evidently only serve with C as keynote. If, for example, we start from D instead of C, we find E a tolerable, though not quite correct, second to D: but the third and seventh of the scale are entirely wrong. Were the major and minor

tones equal, and each semitone exactly half a tone, the insertion of a note in the middle of each tone dividing the seven intervals would make it immaterial where the scale began; any one of the twelve notes becoming alike available as a keynote; and though such equality is contrary to the immutable principles of harmony, an arrangement based on it is found practically to give but little offense to the ear. In what is called the *equal temperament*, the twelve intervals are all of the same length, and no advantage is given to one key over the rest. This is, in theory at least, the temperament adopted in the pianoforte. Another system, known in this country as *Smith's* or the *vulgar temperament*, in which some keys were favored at the expense of others, has been much used in organs. While the keys of B \flat , F, C, G, D, and A are more perfect than on equally tempered instruments B \flat , A \flat , D \flat , and F \sharp contain some very harsh intervals. The bad fifths and thirds which exist in these keys are designated by musicians by the name of *wolf* intervals. This mode of tuning the organ is being more and more abandoned for the equal temperament, or an approximation to it. The different characters of the various keys often observed on the pianoforte, as well as the organ, could have no existence were the temperament absolutely equal, and arise out of the circumstance that this strict equality is not altogether adhered to in practice.

TEMPERANCE, a magisterial dist., Amherst co., Va. Pop. '90, 3635.

TEMPERANCE. *History of the Movement.*—The origin of the temperance movement dates from the beginning of the present century; and the merit of having taken the first steps in the matter belongs to America, where the vice of drunkenness appears to have reached an alarming height about that time. In the month of April, 1808, a society was established at Moreau, county of Saratoga, in the state of New York, consisting of 43 members; one of whose rules was as follows: "Art. 4. No member shall drink rum, gin, whisky, wine, or any distilled spirits, or compositions of the same, or any of them, except by the advice of a physician, or in case of actual disease (*also excepting at public dinners*), under the penalty of 25 cents, provided that this article shall not infringe on any religious rite." This society had other rules prohibiting members (under penalties) from offering any of the above liquors, or from being intoxicated; but though it continued to exist for 14 years, it does not seem to have accomplished much good. Gradually, however, the attention of the clergy and of philanthropical laymen was called to the subject; and after a series of sermons had been preached and published against a vice whose rapid progress was threatening (according to Dr. B. J. Clarke) to make the Americans "a community of drunkards," a society was started at Boston (Feb., 1826), called The American Temperance Society, "to restrain and prevent the intemperate use of intoxicating liquors." In 1829, The New York State Temperance Society was formed; and before the close of the year, 1000 local societies, with 100,000 members, were in existence, and a periodical entitled *The Journal of Humanity*, established to promote the new movement. Rumors of the progress of temperance societies soon reached the old world, and in Aug., 1829, a society was started at New Ross, in the county of Wexford, Ireland, under the auspices of the Rev. George Whitmore Carr, the members of which pledged themselves "to abstain from the use of distilled spirits, except as a medicine in the case of bodily ailment;" and further, "neither to allow the use of them in their families, nor to provide them for the entertainment of friends." Simultaneously, a movement in favor of temperance was begun in Belfast and the north of Ireland, by the Rev. Dr. Edgar, Rev. Dr. Cook, and Rev. Mr. Morgan, and before 12 months were over, 60 societies had been constituted, numbering about 3500 members, both Catholics and Protestants. Meanwhile, Scotland had not been uninfluenced. As early as Oct., 1829, Mr. John Dunlop, of Greenock, a justice of peace for Renfrewshire, after lecturing on the subject of temperance in Glasgow, Sterling, and elsewhere, succeeded in forming a society at Greenock, the first in Scotland, and the precursor of The Glasgow and West of Scotland Temperance Society, formed in the ensuing November. Mr. Dunlop is thus entitled to be considered "the father of temperance societies in Great Britain." In his early labors, he was greatly assisted by Mr. William Collins of Glasgow, who became the editor and publisher of the *Temperance Record* (1830-35). The rules of The Glasgow and West of Scotland Temperance Society were substantially the same as those of the American and Irish societies—the members voluntarily agreeing "to relinquish entirely the use of ardent spirits, except for medicinal purposes," although "the moderate use of other liquors is not excluded." The zeal and activity of this society were remarkable. According to the report read at the first annual meeting (Dec. 30, 1830), it had circulated in the course of the year 425,300 tracts and 20,200 pamphlets, and numbered in Glasgow alone 5,072 adherents; while it was stated that throughout Scotland at large there were 130 societies, and 25,478 members. It is not necessary to follow further in detail the course of the temperance movement, *strictly so called*, in Scotland, except to remark, that numbers of the clergy now began to interest themselves in it, and at the close of 1831, there were 187 ministers of various denominations in Scotland connected with the cause; but we must now notice the introduction of a new and more stringent application of the temperance principle. On Sept. 21, 1830, Mr. John Davie, and several other members of the temperance society of Dunfermline, pledged themselves to "total abstinence from all intoxicating liquors—small-beer excepted, and wine on sacramental occasions;" and in the course of the next two years, "total abstinence societies" were started in Glasgow, Paisley, and other places. In 1830, the temperance movement

extended to England. Mr. Henry Forbes, a merchant of Bradford in Yorkshire, happening to be in Glasgow on business, had attended one of the meetings of the Glasgow society, became deeply interested, and on his return home took steps to organize a Bradford society (Feb. 2, 1830). Another society was formed at Warrington (April 4, 1830); a third at Manchester (May 12, 1830); and by the close of the year, about 30 temperance societies were in existence, numbering in all 10,000 members. In June, 1831, The British and Foreign Temperance Society was organized in London, mainly through the persevering efforts of Mr. William Collins of Glasgow. This was for many years the leading society of the party, its patron being the bishop of London, and its vice-presidents including several other prelates, distinguished officials both civil and military, and a few members of parliament. The pledge taken by its members was simple: "We agree to abstain from distilled spirits, except for medicinal purposes, and to discountenance the causes and practice of intemperance." We have not space to narrate its history and progress in detail, but we may notice that it was instrumental in awakening an interest in the temperance movement both in the army and navy, and that, in the course of a single year (1831-32), it could boast of having induced 400 old Greenwich pensioners to give up their grog.

Gradually, however, the more fervid friends of temperance in England arrived at the same conclusion as the Dunfermline "reformers"—viz., that a crusade against gin and other "alcoholic" liquors was not enough; that "beer" was the great cause of drunkenness in their country, and that nothing but total abstinence from all intoxicating drinks would cure the evil. The movement in this direction first took shape at Preston in Lancashire, in Sept., 1832, when Mr. Joseph Livesey, and some other members of the temperance society there, pledged themselves "to abstain from all liquors of an intoxicating quality, whether ale, porter, wine, or ardent spirits, except as medicines." An active propagandism in all the principal towns of Lancashire followed, and a considerable number of adherents were gained to the new cause. In Sept., 1833, according to the commonly received story (see Burne's *Teetotaler's Companion*, p. 333), the notable word *teetotal* was first used. A certain Richard Turner, or, as he was more generally called, "Dicky Turner," a plasterer's laborer or *lime-larry*, who was much given to holding forth in the Lancashire dialect at the meetings of the new sect, happened in the course of a philippic against temperance to say: "I'll hev nowt to do wi' this moderation—*botheration*—pledge; I'll be reet down tee-tee-total for ever and ever." "Well done, Dicky!" said Mr. Livesey: "that shall be the name of our new pledge." This origin of the word, which appears to make it but a stuttering pronunciation of *total*, has, however, been disputed; and it is affirmed that the term is simply a Lancashire phrase for final, thorough, or complete; thus, when a man is discharged merely for want of work, he is said to be *sacked*, but when discharged from inability to work, *teetotally sacked*. Whatever may have been the origin of the term, the new sect was resolved to be "thorough." In April, 1834, a Youths' Temperance Society, on strictly teetotal principles, was formed at Preston; and before a year had passed it reckoned nearly 1000 members. By dint of zeal, respectable teetotal societies were also established at Manchester (Aug., 1834), Lancaster (Nov., 1834), Colne (Dec., 1834), Isle of Man (Dec., 1835), and numerous other places. Meanwhile (Sept., 1835), a conference of Lancashire and Yorkshire delegates was held at Manchester, and a new general society formed under the title of The British Association for the Promotion of Temperance on the Principle of Total Abstinence from all Intoxicating Liquors. This title clearly indicated the ambitious views of the new sect. It wished, and it hoped erelong, to speak in the name of the whole temperance party; and as early as 1836, one of the Yorkshire district societies, that of Wilsden, ventured to memorialize The British and Foreign Temperance Society of London on the subject of the total abstinence pledge. The answer that it received showed that a disruption was not far off. In Scotland and Ireland, the progress of teetotalism, as distinct from temperance, was not at first very marked; but its votaries were resolute, and held vehement discussions, public and private, with the advocates of the rival system, in which they were generally considered victorious by the crowds before whom they disputed. During 1834-35, teetotalism was struggling hard for recognition in London—the influential leaders of the old temperance society being dead against it. At length, however, owing to the persevering efforts of Mr. Livesey of Preston and other enthusiasts, the teetotalers got a footing, and, in Sept., 1835, established The British Teetotal Temperance Society, which, in Aug., 1836, was merged into The New British and Foreign Society for the Suppression of Intemperance. Teetotalism now in turn began to get the upper hand, and in the course of the next two or three years the "moderate" party almost disappeared; the majority of its members doubtless passing over to the ranks of the total abstainers. But these now fell out among themselves. Up to 1839, The New British and Foreign Society had two pledges, the long and the short; the former including the "neither give nor offer" clause; and the latter omitting it. The more rigorous teetotalers made strenuous efforts to get the "short" pledge abolished, which were as strenuously opposed, and in a very brief period the whole teetotal world was up in wild commotion on the subject. Various meetings of "delegates" from the different societies in England, Scotland, and Ireland were held in London in May, 1839, under the presidency of earl Stanhope, and scenes of the utmost disorder ensued. The result was a temporary disruption, and the formation of two socie

ties. Still the cause prospered in spite of fierce distractions. Strong provincial associations were formed in Yorkshire, Leicestershire, Lancashire, Norfolk, and Cornwall and Wales, almost always on the "long pledge" principle. In Scotland, the "long pledge" took deep root; indeed, after 1837-38, the "short pledge" was scarcely ever thought of. But it was in Ireland that the most brilliant successes attended the movement. In 1838, Father Mathew (q.v.) commenced his extraordinary career, and in less than two years, 1,800,000 men and women were enrolled in Ireland's Great National Total Abstinence Society.

The subsequent history of the movement must be briefly sketched. In Nov., 1842, the disruption, above mentioned, of the British and Foreign Temperance Society was healed, and the two societies which that disruption had called into existence were amalgamated in The National Temperance Society. The work of proselytizing then went on vigorously. Innumerable tracts were circulated, and all Britain echoed with the noise of infinite speech. Excursions, processions, Exeter hall demonstrations, incessant tea-parties, etc., were got up with enthusiasm, which speaks volumes for the energy and sincerity of the teetotal agents. But in a less showy though more noble way, the missionaries of the new faith pursued their benevolent work in the lanes and alleys of large cities, the haunts of profligacy and dissipation, where they sought out the homes of drunkards, and tried (not without success) to rescue them from the power of the horrible vice that was dragging them to destruction. Action of this sort—whatever one may think of the movement as a whole—is to be spoken of only with reference. In Aug., 1846, The World's Temperance Convention met in London, on which occasion 302 delegates were present, representing different societies in the United Kingdom and the United States. Since then, the temperance cause has steadily, if not rapidly, progressed. It has recently been estimated that there are not fewer than 4,000,000 total abstainers (inclusive of juveniles) in Great Britain and Ireland, and a much greater number in the United States of America. Of late years, total abstainers have devoted themselves mainly or largely to advocating the necessity or propriety of imperial legislation on the subject of intoxicating liquor.

One of the recent developments of the temperance movement is that known as *Good Templarism*. It originated in New York in 1851, and rapidly spread through the United States. In 1868, the order established itself in England, in 1869 in Scotland, and in 1870 in Ireland. Its progress has been singularly rapid. In England alone, exclusive of Scotland, Ireland, and Wales, there were in 1875 no fewer than 3,570 "lodges," having 168,425 members, estimated in 1880 to have increased to more than 200,000 persons. These of course do not represent absolutely new adherents to the temperance cause. They are in many cases members drawn from the older temperance societies, though it is also an undoubted fact that the order has been very successful in making fresh converts to the cause of total abstinence. The name is derived from the famous Knights Templars, and originated in a fanciful analogy between the functions of the ancient order of military monks, and the modern disciples of temperance. As the former were enrolled to defend the holy sepulcher and the interests of religion, so the latter are banded together to protect Christianity against a worse foe than the Saracens, viz., "the drinking institutions of the land." It is professedly a *religious* movement, and its ritual is evangelical. Its platform is absolute prohibition of the manufacture, importation, sale, or use of all intoxicating liquors as beverages: but it owes its great popularity to certain peculiarities in its constitution, its picturesque or showy ceremonial, and its aim to combine social and festive amusements with missionary zeal.—See *Good Templarism*, by the Rev. George Gladstone (Glasgow, 1872). A more recent movement, The Blue Ribbon Army, is very successful. The Salvation Army obliges its members to be abstainers.

Pleas and Counter-pleas.—The question of abstinence from intoxicating liquors is capable of being argued on three distinct grounds, *scriptural*, *physiological*, and *social*. We propose to furnish a brief synopsis of the leading arguments *pro* and *con* under each of these aspects. First, then, the *scriptural argument*.

The scriptural argument in favor of abstinence from intoxicating liquor may be briefly stated. The only "strong drink" mentioned in the Bible is wine. It is both praised and blamed. The question raised by teetotalers is: Are the sacred writers referring in both cases to the same kind of wine? This they deny, and endeavor to make good their denial by an appeal to the original Hebrew. On examination it is found that ten or twelve different designations for wine are used, but the two by far the most frequent are *yayin* and *tirōsh*. The first of these is the generic term for wine, and therefore (say the advocates of total abstinence), as it *must* embrace fermented liquor, it is the word used when wine is denounced. Thus, it is *yayin* that is a "mocker" (Prov. xx. 1), that is not to be looked upon (Prov. xxiii. 31, 32), etc. On the other hand, when wine is praised, *tirōsh* is the word used, and *tirōsh* (it is asserted) means the wine in clusters, that is, the actual grape itself, or the unfermented juice thereof, then, as now, liberally drunk as a beverage by the inhabitants of Syria and elsewhere. The application of this view to the New Testament is obvious. If there was a wine that might be used, as well as a wine that was condemned—which, ask the teetotalers, would Christ and his apostles be most likely to sanction? The wine that "maketh red the eyes," that "biteth like a serpent, and stingeth like an adder," that "deceiveth," that "maketh drunken" and "mad;" or the wine that "maketh glad the heart," that is "good," a "blessing," etc.:

—in a word, *yayin* in any of its dangerous forms (*sôbe*, from the root to “soak;” *chemer*, the “foaming or bubbling;” and *mesec*, *mezeg*, *mimsac*, the mixed wines), or the innocent *tîrôsh*, that cheers, but not inebriates? It is conceived that there can be but one answer to this question, and that every candid and reverent Christian must be forced to the conclusion, that the wine which Jesus made at the marriage-feast at Cana of Galilee, and used in his last supper with his disciples, and which Paul advised Timothy to drink for his stomach’s sake, was the unfermented, innocuous, and popular *tîrôsh*.

To this it is replied that the distinction made between *yayin* and *tîrôsh* does not exist. Both parties are agreed that the former term is the generic one (corresponding with the Greek *oinos*, the Latin *vinum*, and the English *wine*, with all of which it is believed to be etymologically connected); but it is denied by the scriptural opponents of total abstinence that *yayin* means fermented, and *tîrôsh*, unfermented wines, exclusively. Not to trench upon the chemistry of the question, which, it is affirmed, wholly disproves the possibility of the “juice of the grape,” being kept for any length of time without undergoing a process of fermentation, and thereby acquiring to a certain degree intoxicating properties, it is alleged that the etymology of *tîrôsh* does not favor the teetotal view. According to Gesenius, it is derived from the root *yârash*, “to get possession of;” that is, of the brain. Dr. Lees, indeed, quotes Bythner as suggesting that it may have been so named because the vine was a “possession” in the eyes of the Hebrews; but this is extremely improbable, and in the absence of other explanations, that of Gesenius is certainly to be preferred. Again *tîrôsh* is not exclusively used to denote the “fruit” (strictly so called) of the vine; the dreaded *yayin* performs the same harmless function—e.g., in Jer. xl. 10, 12, where it is connected with a verb significant of “gathering,” and in Ps. civ. 14, 15, with another expressive of growth. It is even denied that *tîrôsh* is ordinarily to be so understood, for although, being mostly found in connection with “corn,” the verb applied to the consumption of that article of food is by *zeugma* made to apply to the “wine” also, yet in the only passage where the act of consuming *tîrôsh* alone is mentioned (Is. lxii. 8, 9), the verb is *shâthâh*, which invariably signifies the act of drinking. Lastly, it cannot be shown that *tîrôsh*, when it does mean wine, means innocuous wine. No doubt, *yayin* is the one generally employed when wine is denounced, and *tîrôsh* when it is praised, but this is not uniformly the case, for in Hos. iv. 11, “whoredom and wine (*yayin*) and new wine (*tîrôsh*) take away the heart,” *tîrôsh* actually forms (as has been remarked) “the climax” of intoxicating influences. The conclusion, therefore, to be drawn from a consideration of Scripture is, that the distinction insisted on by total abstiners between the two terms—viz., that the one (*yayin*) means fermented, and the other (*tîrôsh*) unfermented wines, is one that cannot be maintained. Both must be held as referring to fermented intoxicating wine; and the praise of *tîrôsh* is simply to be considered a recommendation of the moderate use of ordinary wine, as the condemnation of *yayin* is to be regarded as a solemn prohibition of excess in the same.

The physiological argument in favor of total abstinence necessarily takes various shapes; for it is concerned with physiological questions which are yet, to a great extent, matter of opinion—of speculation and conjecture, not of science. A question arises upon three distinct points: 1st, the effects of alcoholic liquors in quantities sufficient to produce intoxication; 2d, their effects when habitually used in moderate quantities; 3d, the effect of abstaining from them altogether.

Upon the first point, teetotalers usually maintain that insanity, idiocy, almost every form of organic disease, many chronic, not a few acute disorders, are frequent results of habitual intoxication; that the children of drunkards are often idiotic, and have transmitted to them various diseases, which are produced by excessive drinking—which, therefore, tends to the deterioration of the race; that drunkards are always the first victims of epidemics; and that it can be shown from tables of mortality that drinking has a marked effect in shortening life. It is not disputed that many of these effects can be connected with the habitual use of liquors in excess; but as to some of the most striking of them, it is denied that they are physiological effects of such excess—being not direct results of hard drinking, but due to the bad conditions under which poor people who drink hard usually live. The question between teetotalers and those who differ from them, at this point, however, is only a matter of degree. The latter admit that alcohol, in narcotic or intoxicating quantities, produces only injurious results. In such quantities it has a deteriorating, a devitalizing influence upon the brain and nervous tissue, and habitual excess in its use is attended by a progressive impairment of nervous structure, indicated at length by such results as epilepsy or delirium. See INTOXICATION. But the results of excess differ greatly, it is said, in the case of different persons, so that, not unfrequently, many years of hard drinking do not affect the system of the drinker in a marked degree.

It is upon the second point—the habitual use of alcoholic drinks in moderation—that the opinion of teetotalers seriously conflicts with that of many physiologists. The teetotal argument—leaving out minor points, such as an alleged effect of alcohol in impairing the digestion—may be stated thus: 1. Alcohol can never have been intended by nature for the food of men. It is never produced spontaneously in nature. The vegetable world yields in abundance the principles which form the flesh, and those which keep up the heat of the body, but the healthy plant never produces alcohol. In the body too, in health, food is never converted into alcohol. And the body does not

merely not produce alcohol; it treats it as a foreign element, and gets rid of it as fast as possible. 2. Alcohol in the body, by taking up the oxygen supplied through the lungs, checks the burning of tissue, upon which life and the production of energy, muscular or mental, depend; and similarly it impedes the efforts of the body to get rid of the waste matters which are the products of the burning. It thus lowers vitality, vitiates the blood, and prevents the production of healthy fiber. Toddy or beer taken at bed-time, instead of being favorable to health, has just the same effect, according to Dr. Carpenter, with sleeping in a four-post bed with the curtains carefully tucked under the bed-clothes. In either case, that is, there is a diminution of the supply of oxygen required for vital processes, especially for burning the waste of the body. 3. The stimulation produced by alcohol is succeeded by a recoil or reaction; and to produce a certain effect of stimulation, the quantity taken must constantly be increased. From this cause—to say nothing of social influences connected with drinking calculated to produce the same result—moderate drinking tends to pass into excessive drinking, about the evil consequences of which there is no dispute.

The physiological opinion opposed to those arguments is, that while alcohol, like other similar substances, has in large quantities a narcotic, a devitalizing effect, it has in small quantities a stimulating effect, between which and narcotism there is a difference, not of degree, but of kind. The stimulating effect is precisely the same with that of highly-nutritious and easily digested food; as regards the vital functions, it differs from the effect of ordinary food only in rapidity of production. It does not substitute an abnormal for the normal action of the bodily organs; it restores their natural functions; and it is capable of rectifying either deficient or redundant functional action. The only positive difference of effect between ordinary food and alcoholic stimulation is, that the latter does not, to any great extent, add to the bulk of the body. There is no recoil or reaction after it, except that, as in the case of ordinary food, the effect is exhausted after a time. There is nothing to support the belief in a reaction, except the depression involved in the gradual recovery from the narcotic effect of a large quantity of alcohol; but between the narcotic effect of a large, and the stimulating effect of a small, quantity, there is, as already said, a difference of kind—their connection is merely accidental. And the experience of mankind—the fact that moderate drinking does not usually pass into excessive drinking—sufficiently shows that it is not found necessary to increase the quantity used for stimulation. Since stimulation restores the natural functions, it, of course, is capable of removing the consequences of functions being perverted. Thus, it is maintained that, among other things, it gives relief from pain and muscular spasms, reduces the circulation when too rapid, produces healthy sleep, and removes general debility, as well as the fatigue of special organs. Whether it, to an important extent, affects the waste of tissue, or keeps waste matters in the blood, is at present undetermined; however this may be, there is no justification for holding that life is to be measured by the aggregation of tissue, or the rapidity of bodily changes. The notion that alcohol checks the burning of tissue by taking up the oxygen received by the lungs, originated when it was believed, upon the authority of Liebig (it was so believed until a few years ago, but the contrary is generally held now), that alcohol was altogether decomposed in the body. If these views are correct, it follows that alcohol, taken cautiously and in small quantities—the quantities varying with the circumstances and with the constitution of the individual—may be used not only with safety but with advantage.

Under the third head teetotalers, of course, maintain that total abstinence is highly favorable to health. They adduce their personal experience; the mortality statistics of one or two regiments and of ships' crews mainly, or entirely, made up of abstainers; the evidence of arctic voyagers on the one hand, and of travelers in tropical regions on the other, to prove that in every climate health can be maintained, and is most likely to be maintained, when no use is made of alcoholic drinks. On the other side, the fact that men of all races use alcoholic beverages is held to show that men, living as men must usually do, find those beverages useful, if not necessary. It is not disputed that many persons live in health without them—that persons having an abundance of wholesome food, not over-worked, living in well-constructed houses, and in wholesome air, can usually dispense with them. But when some, or all, of those conditions are wanting—which in towns, at any rate, happens in all but exceptional cases—it is alleged that a nearer approach to health is made when a moderate use is made of alcohol.

The social arguments in favor of total abstinence, though very weighty and earnestly insisted upon, can be indicated in a few sentences. It is affirmed that the use of alcoholic drinks is at the root of all the misfortunes of the poorest and most numerous class, that it is the chief cause of pauperism, the chief cause of crime, a frequent occasion of immorality; that it lowers the health and shortens the life of the great mass of artisans and laborers, makes their homes wretched, and exposes them and their families to the evils and temptations of chronic destitution. Then, such are the seductive influences of drink and good-fellowship, that moderate drinkers are in danger of becoming drunkards; thus the use of liquors effects the ruin of a considerable percentage of the middle and upper classes. Total abstinence is demanded as a measure of personal precaution, because no one who drinks at all is safe against falling into drunkenness; as a patriotic duty, incumbent upon those who desire the improvement of the poorer classes; as a duty

of example which every man owes to his neighbor, and which, involving self-denial, must have a favorable reflex influence upon character. On the other side, it is not denied that drinking is closely connected with, or that it exasperates, the misery undergone by the poor; but it is denied that it is the cause of the misery. It is maintained that drinking must be regarded as an effect of the bad conditions inherited by the poor, and under which they live. Persons born in close alleys, and brought up in foul air, living always from hand to mouth, often upon insufficient or unwholesome food, feel (it is said) a need of stimulants to support vitality. It is affirmed that the fluctuations of crime (properly so called) do not depend upon the amount of drinking, but—so far as they can be traced to one circumstance—upon variations in wages; that it is destitution, not drunkenness, that contributes most largely to the production of crime. The drunkenness, the crime, the pauperism, it is maintained, cannot be permanently reduced except through a material and moral improvement being effected among the poor. Then it is denied that moderate drinkers, in general, are in any danger of becoming drunkards; it is persons wanting in prudence, and of intemperate constitution, who are exposed to that danger.

Of late years total abstiners—in unison with others who, though not themselves abstiners, are anxious to promote public sobriety—have exerted themselves to obtain, in one shape or another, a legislative prohibition of the trade in drink. This movement was set on foot in Great Britain in 1853, by an organization called "the United Kingdom alliance," on account of the success which had crowned the exertions of teetotalers in Maine and many other of the United States. In Maine the liquor traffic was suppressed in 1846; the law was made more stringent by a provision for confiscating all alcoholic drinks in 1851; and though in 1856 the existing laws were repealed, and it became lawful to distill spirits, to sell spirits, and to have spirits in possession, drinking-houses continued to be prohibited. The "alliance" soon found that there was no possibility of carrying a Maine liquor-law through the British parliament; and they accordingly confined themselves to asking for a permissive bill, enabling the ratepayers of a parish, if a majority of two-thirds think fit, to suppress all public-houses within the parish. They now demand local option (see PROHIBITION). They support the bill upon the merits by a variety of arguments. Alcohol, they say, being a poison, its sale ought to be subject to the same restrictions as that of other poisons. The legislature has admitted the exceptional and dangerous nature of the liquor trade, by putting it under strict regulation; in consistency, it should suppress it as a trade altogether. They allege that the amount of drinking in a place always varies directly with the number of public-houses; and then that the amount of crime and of pauperism varies directly with the amount of drinking. In 1857 Dr. Lees calculated the expense of the use of liquors to this country at 120 millions a year—the cost of the liquor being put at 60 millions, and the remainder of the amount made up by allowing for the crime and pauperism caused by drinking, the loss of time in drinking, and, through disease induced by drinking, the waste of life consequent upon it and many minor items. This money, it is said, if not spent upon drink, would have a marvelous effect in improving the condition of the poor. On the other side, it is maintained, *in limine*, that the subject-matter of this bill is so very important, and so full of difficulty, that parliament should not delegate its functions in respect of it to the ratepayers; also, that to do so would be to plant, in every parish in the country, the seeds of perpetual strife. Upon the merits it is said that a prohibitory law could not be carried out—at any rate, in large towns where the worst evils connected with drinking are found; and that systematic attempts at evasion would be made, which would demoralize the people, and put them in chronic antagonism to the law. Besides the arguments already stated upon this side, it is urged that—excepting the case of poisonous substances—it is no part of the duty of a governing body to say to its people: You shall not spend your money upon this or that; that it is unreasonable, in a fiscal point of view, to speak of the national resources being wasted upon liquors any more than upon tea or beef, or other substances that perish with the using; and that the power of procuring articles which are desired is what men work for—the great motive of industry. It is also maintained that compulsory abstinence from drink would not produce the same results as voluntary abstinence; that men would seek indemnifications, resorting, it might be, to other and more injurious narcotics than alcohol, and to vices which might be even more injurious than drinking. It is said that abstinence, to be valuable, must be a sign of a moral improvement; and that it is safest we should leave the poor to face the temptations of their situation, trying to fortify them against these temptations by education, by giving them just, moral, and religious views; at the same time holding before them the spectacle of temperance and its results in the case of the more comfortable classes. See PROHIBITION, etc.

The following are the leading organizations in Great Britain that, with various modifications of creed, carry on the temperance agitation. They can claim as directors and advocates men of acknowledged position and ability; and the aggregate sum of money spent annually is very great. The National Temperance League, London (organ, the *Weekly Record*); the United Kingdom Alliance, Manchester, with numerous branches (organ, the *Alliance News*); the Church of England and Ireland Temperance Society, London (organ, the *Church of England Temperance Magazine*); the Scottish Temperance League, Glasgow (organ, the *League Journal*); the National Band of Hope Union, London

(organ, *Band of Hope Review*). Besides these, the Roman Catholic and Methodist branches of the temperance society form distinct organizations, while the Order of Good Templars has its organs in the United States, and in England, Scotland, and Ireland. See **BAND OF HOPE**. For temperance as a political question, see **PROHIBITION PARTY**.

TEMPERATURE OF THE BODY IN HEALTH AND DISEASE. It is universally admitted as a result of the observations of numerous physiologists, among whom our own countryman, Dr. John Davy, stands pre-eminent, that although the range of temperature varies in different parts of the human body, the normal temperature at completely sheltered parts of the surface amounts to $98^{\circ}.4$, or a few tenths more or less in temperate climates; and that if there is a persistent elevation above $99^{\circ}.5$, or a depression below $97^{\circ}.3$, some form of disease is certainly indicated. (In warm-blooded animals, generally, the temperature is one degree lower at completely sheltered parts of the surface than in the back of the mouth, or other accessible internal parts.)

Some of the circumstances which cause a deviation from the normal temperature are mentioned in the article on **ANIMAL HEAT**. It may be further noticed, that exposure to cold without exercise, and sustained mental exertion, reduce the temperature, and that the amount of heat is at first reduced after a full meal, although, as stated in the above-named article, it subsequently rises. Moreover, in the tropics, the average temperature is nearly 1° higher than in temperate regions.

When the temperature rises in cases of disease, the following relation to its augmentation and that of the pulse has been established: *an increase of temperature of 1° above 98° corresponds with an increase of 10 beats of the pulse in the minute*. Thus, if the pulse is 60 at 98° , it is 70 at 99° , 80 at 100° , and so on. It is now established beyond all doubt, by the observations of Wunderlich, Virchow, and many other foreign physicians, and by Parkes, Jenner, Aitken, and Ringer in this country, that the preternatural heat which in certain cases can be detected by the thermometer, and may exist to the extent of 4° , 6° , or even 8° above the healthy average, and which varies in amount in different diseases, in different persons, and at different times of the same day, is the essential symptom of fever. Dr. Davy, in his *Physiological and Anatomical Researches*, vol. i. p. 206, describes the case of a lunatic soldier, in whom the accidental discovery that his temperature was 6° above the normal standard, led to the detection of tubercular disease of the lungs and intestines. Wunderlich, whose experience embraces at least half-a-million exact thermometric observations, bears unqualified testimony to the value of this mode of investigation in the early detection of disease, and as often furnishing an important guide to treatment. Some of these instances are quoted by Dr. Aitken in his *Science and Practice of Medicine*, 3d ed. vol. i. pp. 44-46.

We give in a condensed form a few of the more important of these observations. In *ague*, the temperature of the body begins to rise several hours before the beginning of the paroxysm, and after the disease *seems* to have disappeared, a periodic increase of the temperature may still be detected, and as long as this continues, the patient is not really cured. In *typhoid fever*, the rise of temperature, or its abnormal fall, will indicate what is about to happen three or even four days before any change in the pulse or other sign of mischief has been observed. A sudden fall of temperature has thus denoted intestinal hemorrhage several days before it appeared in the stools. A fall as low as 93° was noticed by Parkes in a case of this kind. When a person, who yesterday was healthy, exhibits this morning a temperature above 104° , it is almost certain that an attack of ephemeral fever or *ague* is coming on, and should the temperature rise up to or beyond $106^{\circ}.3$, the case will certainly turn out one of *ague* or of some other form of malarious fever. If, during the first day of illness, the temperature rises to 106° , it is certain that the patient does not suffer from typhus or typhoid fever; and if the temperature of a patient, who exhibits the general signs of pneumonia, never reaches $101^{\circ}.7$, it is certain that there is no soft infiltration in the lungs. "In typhoid fever, a temperature which does not exceed on any evening $103^{\circ}.5$, indicates a probably mild course of fever. A temperature of 105° in the evening, or 104° in the morning, shows that the attack is a severe one, and forebodes danger during the third week. On the other hand, a temperature of $101^{\circ}.7$, and below, in the morning, indicates a very mild attack, or the commencement of convalescence. In pneumonia, a temperature of 104° and upward indicates a severe attack. In acute rheumatism a temperature of 104° is always an alarming symptom. In a case of jaundice otherwise mild, an increase of temperature indicates a pernicious turn. In tuberculosis, an increase of temperature shows that the disease is advancing, and that untoward complications are setting in. In short, a fever temperature of 104° to 105° in any disease indicates that its progress is not checked, and that complications may still occur."—*Op. cit.*, p. 21. We may further observe that, from the observations of Dr. Sidney Ringer, a persistent elevation of temperature exists as an invariable precursor of the growth of tubercle in any organ. As a general rule, when the temperature rises continuously to $106^{\circ}.2$, the prognosis is unfavorable; and when it rises to 110° , a fatal issue is almost certain. The diseases in which the highest temperatures have been observed are scarlatina, in which it has been noted at 112° , and tetanus, in which, at the period of death, it was $112^{\circ}.5$, and an hour afterward was $113^{\circ}.8$. In Dr. Aitken's work, the reader will find a series of diagrams illustrating the range of temperature in *ague*, *erysipelas*, *measles*, *pneumonia*, *simple continued fever*, *scarlatina*,

small-pox, typhoid and typhus fevers, etc., together with a full description of the instruments to be used, the method of using them, and practical rules for recording observations.

TEMPERED, or TOUGHENED, GLASS, glass in a peculiar molecular condition, produced by placing it while hot in a tight box containing oil. The box is tight to prevent ignition of the oil. The surface to variable depths, depending upon the conditions of the experiment, becomes very hard, and apparently tough, for articles of glass prepared by this method may be thrown with considerable violence upon the ground without breaking. When, however, they do break they are shattered into minute fragments, after the manner of prince Rupert's drops (q.v.), indicating that the molecules of glass are held together in a condition of strain, and this is shown to be the case by an examination of the optical properties of the glass. Continued jarring will produce disintegration, and the material will not bear to be ground. It is the invention of M. de la Bastie of France.

TEMPERING STEEL. A peculiar effect is produced upon steel by heating it to redness, and then suddenly cooling it. By this means, extreme hardness is obtained. Steel is so susceptible to this process, called tempering, that almost any degree of hardness and brittleness can be obtained. If, for instance, we make a piece of steel red-hot, and then plunge it into cold water, it becomes hard and brittle when cold, and is actually, though slightly, increased in bulk. But if we reheat the metal, and allow it to cool slowly, it again becomes soft and malleable as before. Moreover, if we again reheat it, but not to redness, and cool it suddenly, it is still further softened. If, before reheating, the surface has been polished, a beautiful shade of color is produced by the heat, which is varied according to the temperature employed; and so exactly is this the case, that the experienced manipulator is entirely guided by the color produced, instead of by nice regulations of the heat applied. For ordinary operations, the metal is cooled by plunging it in cold water; but oil, mercury, and saline solutions are used for special purposes. An exact series of experiments has proved that the following colors are produced at the temperatures given: very pale yellowish, by 430° Fahr.; pale straw, 450°; yellow, 470°; brown, 490°; mottled brown, 510°; purple, 530°; bright blue, 550°; blue, 560°; dark blue, 600°.

TEMPLARS, GOOD. See **TEMPERANCE.**

TEMPLAR, KNIGHTS, a celebrated religious and military order, founded at Jerusalem in the beginning of the 12th c., by Hugues de Paganus, Geoffroy de St. Omer, and seven other French knights, for the protection of the Holy Sepulcher, and of pilgrims resorting thither. Baldwin II., king of Jerusalem, bestowed on this order their first place of residence; and an additional building was acquired from the abbot and canons of the church and convent of the temple, whence the order obtained the name of the "poor soldiers of the temple of Solomon," afterward abbreviated into templars. The knights were bound by their rule to hear the holy office every day, or if prevented by their military duties, to say a certain number of paternosters instead; they were to abstain from flesh four days in the week, and from eggs and milk on Fridays. They might have three horses and an esquire each, but were forbidden to hunt or fowl. In the earlier period of their history, the templars made a great show of poverty, contrasting much with their later condition. After the conquest of Jerusalem by the Saracens, they spread over Europe; their valor became everywhere celebrated; immense donations in money and land were showered on them; and members of the most distinguished families thought themselves honored by enrollment in the order. In every country where they existed, they had their governor, called the master of the temple or of the militia of the temple. The templars had settlements in England from an early period. The first was in London, on the site of Southampton buildings, Holborn; but from 1185 their principal seat was in Fleet street, still known as the temple.

The templars were at first all laymen and of noble birth. Pope Alexander III., however, in 1162, authorized the admission of spiritual persons not bound by previous vows, as chaplains to the order, who were not required to adopt the military vows. A third class was afterward introduced, consisting of laymen not of noble birth, who entered as serving brothers, some of them being attendants on the knights, and others exercising trades in the houses or lands of the order. Eventually, many persons became affiliated members without taking the vows, for the sake of the protection afforded them. As the power and prosperity of the templars increased, so did their luxury, arrogance, and other vices, which gave the French kings a pretext for endeavoring to suppress them, and lay hold of their possessions. Accusations, many of which were absurd and incredible, were brought against them by two members of their own body. Their principal enemy was Philippe IV. of France, who induced pope Clement V. to accede to a scheme by which the whole members of the order were seized and imprisoned, their lands confiscated, and many of them tried, convicted, and executed for capital crimes. The English templars were arrested by command of Edward II.; and a council held in London in 1309 having convicted them of various crimes, most of which were probably imaginary, the king seized their possessions. In 1312 the whole order throughout Europe was suppressed by the council of Vienne, and its property bestowed on the

knights of St. John, to which latter order their English possessions were formally transferred by a statute of Edward II. in 1323.

The habit of the templars was white, with a red cross of eight points of the Maltese form worn on the left shoulder. Their war-cry was "beau seant;" and their banner, which bore the same name, was parted per fess sable and argent. They also displayed above their lances a white banner charged with the cross of the order. Their badges were the *Agnus Dei*, and a representation of two knights mounted on one horse—indicative of the original poverty of the order.—See Addison's *History of the Knights Templars, the Temple Church, and the Temple* (Lond. 1842); A. O. Haye's *Persecution of the Knights Templars* (Edin. 1865).

As to the modern society called Knights Templar, see ASSOCIATIONS, SECRET AND BENEVOLENT.

TEMPLATE, a mold in wood or metal, showing the outline or profile of moldings, and from which the workmen execute the molding.

TEMPLE (so called because the Knights Templars had one of their branches in that part of London), in its connection with the law of England, is a part of the city of London occupied exclusively by barristers or attorneys, with few exceptions. It is the joint-property of the two Inns of Court (q.v.), called the societies of the inner temple and middle temple, each of which has a right of calling persons to the degree of barrister—a privilege shared by the two other Inns of Court, Gray's Inn (q.v.) and Lincoln's Inn (q.v.). The temple consists of buildings occupied by barristers, who rent the same from the above two societies, who are the private proprietors, and issue their own regulations as to the management of the property.

TEMPLE, DANIEL, 1789–1851; b. Mass.; graduated Dartmouth college, 1817, and Andover seminary, 1820; sailed as a missionary of the American board to the east, 1822, with a printing-press; stationed at Malta, 1822–28, and had charge of the press; resided at Smyrna, 1832–44; returned to America, 1844. He published many books in modern Greek, Italian, and Armenian, wrote many scriptural histories, and edited and contributed to a monthly magazine in modern Greek. His life and letters were published after his death by his son, the Rev. Daniel H. Temple.

TEMPLE, FREDERICK, D.D., b. on Santa Maura, one of the Ionian islands, Nov. 30, 1821; graduated with the highest honors at Balliol college, Oxford, 1842; was fellow and tutor in mathematics; ordained in the church of England, 1846; principal of the training college, Kneller Hall, 1848–55; an inspector of colleges, 1856–58; master of Rugby school, 1858–69; appointed bishop of Exeter, 1869, his confirmation as such being ineffectually opposed because of his share in writing, 1860, the well known *Essays and Reviews*. He was one of the queen's chaplains, and published three volumes of sermons preached in Rugby chapel; was, 1883, April, elected Bampton lecturer at Oxford for the ensuing year; and 1885, Jan., was transferred from the see of Exeter to that of London, left vacant by the death of Bp. Jackson. In 1897 he was made archbishop of Canterbury.

TEMPLE, Sir RICHARD, b. near Worcester, England, 1826; entered the Indian civil service in 1848; was knighted, 1867; became lieutenant-governor of Bengal, 1874; and governor of Bombay, 1877. Returning to England, he was a member of the school board of London, 1886–94, and in 1885 entered parliament. His publications include *India in 1880*; *Men and Events of My Time in India* (1882); *Oriental Experiences* (1883); *Cosmopolitan Essays* (1886); *Palestine Illustrated* (1888); *Memoirs of John Lawrence* and *James Thomason*; *Life in Parliament*; and *Story of My Life*.

TEMPLE, RICHARD GRENVILLE, Earl, 1711–79, b. England; returned to parliament from Buckingham, 1734; and in 1752 succeeded to the earldom. He was a political associate of William Pitt, and held the positions of lord of the admiralty, 1756–57, and lord privy seal, 1757–61. The *Grenville Papers* (1852–53), edited by W. J. Smith, consist of the correspondence between Pitt and George and Richard Temple. They throw much light on the political and court life of the period.

TEMPLE, Sir WILLIAM, an eminent diplomatist and popular writer, was the eldest son of sir John Temple, master of the rolls in Ireland. He was born in London in 1628, studied for two years at Emmanuel college, Cambridge (where he had the celebrated Dr. Ralph Cudworth for tutor), and at the age of 19 went abroad on his travels. He acquired the French and Spanish languages, and also cultivated his taste for English composition. He entered on public life in 1661, as member for the co. of Carlow, in the Irish parliament. In 1665 he was selected to proceed to Westphalia on a secret mission to the bishop of Münster; and on his return he was created a baronet, and appointed resident at the court of Brussels. His most important diplomatic success was the famous treaty of 1668, known as the triple alliance, by which England, Holland, and Sweden bound themselves to unite in curbing the ambition of France. This negotiation was accomplished in five days, in conjunction with the great Dutch statesman, De Witt. At the congress of Aix-la-Chapelle, and at the subsequent treaty of Nimeguen, Temple was also a negotiator. He was long ambassador at the Hague, and assisted in bringing about the marriage of the Prince of Orange with the Princess Mary. Charles II. in vain endeavored to prevail upon him to accept the appointment of secretary of state; but though shunning such arduous duty, he attempted to reform the government by establishing, with consent of the king, a privy council of 30 persons, by whose

deliberations his majesty promised to be guided in all public affairs. As might have been foreseen, so numerous a council, under such a sovereign as Charles, and in times of such fierce rivalry and faction, proved an utter failure. Temple then finally abandoned politics, and retired to the country. In fact, the chief aim and desire of this accomplished statesman was to enjoy lettered ease and leisure, apart from all exciting public care and responsibility. When the revolution placed William III. on the throne, Temple was again solicited to become secretary of state; but he again refused. The remaining ten years of his life were mostly spent at his favorite seat of Moor Park, in Surrey, where he carried out his schemes of planting and landscape gardening, and realized his early wish for studious retirement. During this period he had, as secretary and humble companion, the immortal Jonathan Swift, who regarded his stately self-complacent patron with more fear and distrust than affection, but who ultimately became his literary executor. Temple died at Moor Park, in Jan., 1699. His collected works form four volumes (Lond., 1814).

As an author Temple is now known chiefly by his historical *Memoirs*, and his *Miscellanea*, the latter being a collection of essays on various subjects—as government, trade, ancient and modern learning, gardening, heroic virtue, and poetry. He has been considered one of the reformers of our style; “the first writer,” says Johnson, “who gave cadence to English prose.” His style has quite a modern air, and is smooth, copious, and agreeable. He is too pretentious as respects scholarship and learning, and has no weight as a political writer; but he expatiates very pleasantly on foreign travel and country life, on flowers and fruits, on parterres, terrace-walks, and fountains.

TEMPLE OF SOLOMON AT JERUSALEM (Beth Jahveh). A temple on Mount Moriah, Jerusalem, 2419 feet above the Mediterranean, and built in the fourth year of Solomon's reign. It was the first work of importance constructed by the Jews. It followed the outline of the Tabernacle with doubled proportions and innovations, and was designed as a place for worship, a dwelling for the priests, and a place for public assembly. As all attempts to restore it are conjectural, the best idea is received through comparative study of ancient architecture; and scholars now agree that its style was Phœnician. It is supposed to have resembled the Temple of Astarte at Paphos, and Hierapolis, described by Lucian, offers a parallel, facing the East like Solomon's, decorated with gold work, and having before its portals, adorned with twin pillars, a brazen altar within a walled court. (See T. L. Donaldson, *Architectura Numismatica*, London, 1859.) The chief motives of ornamentation were palm-tree and cherub; the former a common Phœnician device, the latter a variety of sphinx. Tradition has accepted the most extravagant statements regarding the magnificence of Solomon's Temple, the only descriptions of which are I. Kings iv.-ix. (the most ancient and trustworthy); I. Chronicles ii.-vii.; Josephus, *Antiq.*, viii.; and Eupolemus in Eusebius, *Præp. Ev.* Solomon first appealed to Hiram, King of Tyre, for architects and workmen, and, upon agreement of yearly tribute, assistance was granted. Three years were spent in amassing materials. Four classes of men were employed: (1) 30,000 native Israelites working in relays of 10,000 every three months in the forest of Lebanon, whence timber was sent by floats to Joppa, and dragged to Mount Moriah; (2) Phœnicians, who worked for pay; (3) slaves, home-born and captured; (4) vassal Canaanites, numbering 70,000 burden-bearers and 80,000 quarrymen under 3600 Israelite officers. Skilled Sidonian artisans were employed in molding and carving the gold and brass, and coloring and embroidering the hangings with the famous Tyrian dyes of purple and scarlet. The summit of Mount Moriah was enlarged and supported by massive walls, the stones being hewn from the subterranean quarries over which Jerusalem is built, and cisterns and conduits of immense capacity were constructed. The Temple, completed in seven years and a half, was the centre of national life and the symbolical dwelling of Jehovah among his chosen people. None but priests ever entered its sacred portal, and only the High Priest once a year was permitted to approach the Oracle, or Shrine, known as Holy of Holies. The people, who worshipped in the open air in the Outer Court below the “Priest's Court,” never beheld the wonders of the Temple. Briefly, it was a building 60 × 20 cubits and 30 cubits high, of huge stones, roofed and floored with cedar overlaid with gold, having rooms shaped like cubes, and upper stories of light woodwork—all characteristic features of Phœnician architecture. Before the portico stood two bronze pillars—Jachin and Boaz—40 cubits high, with lotus capitals and further decoration of network encircled with pomegranates. Through a door of cypress overlaid with gold the priests entered the sanctuary, decorated with gold and carved with pomegranates, lotus, and palms. Here stood the altar of incense, the table for shewbread, and the golden candlesticks. These, with all the vessels for service, were golden. The Sanctuary was separated from the Oracle by a two-leaved door of wild olive-wood covered with gold and ornamented with cherubim, flowers, and palm-trees. This was always open, but a veil, or tapestry, of purple and crimson, bearing the emblem of the winged cherubim and festooned with golden chains, concealed the Holy of Holies from view. This small room, enveloped in mystery, contained the Ark standing on a rock and protected by Solomon's two cherubim, ten cubits high, with outstretched wings, five cubits long, touching over the Ark and resembling the winged emblems of Egypt and Assyria. The immediate enclosure, 600 feet square, known as the “Priests' Court,” was shut in by three gates, and in it stood the great brazen altar, directly in front of the twin pillars

of the Temple. Not far away was the "Sea of brass" for the ablutions of the priests, consisting of a reservoir, shaped like a lily blossom, festooned with bronze garlands, and standing on the backs of twelve brazen oxen. Five caldrons on wheels for conveying water, and adorned with emblems, stood on each side of the Temple. The "Outer Court," 900 feet square and separated by a wall, contained no permanent structure, but was crowded morning and evening with worshipers and priests, for here the sacrifices of the people took place. The enclosing walls of the Temple and its two courts were 10½ feet high and 9 feet thick.

The dedication (996 B.C.) was delayed nearly a year after the Temple was finished. The relics of the Tabernacle and its ancient furniture were borne from Gibeon in triumphal procession, in which Solomon took part; and, after the people had watched the Ark pass into the Temple, from which it never issued until carried away by Nebuchadnezzar four centuries afterwards, Solomon took his seat on a huge throne erected for the purpose in the "Priests' Court," and visible to the audience in the "Outer Court." In front of him on the altar steps the white-robed priests and musicians stood with their harps, cymbals, and psalteries. At a signal of the trumpets the entire assembly sang hymns of praise, and, after the king's prayer, blessing, and exhortation, followed the stupendous slaughter of 22,000 oxen and 120,000 sheep. To meet the increased demands for service, the duties of the 38,000 Levites were reorganized. The general care of the Temple was given to 24,000; 6000 were made judges and officers; 4000 porters, and 4000 musicians (3700 being singers) appointed for the stately antiphonal and instrumental services. Canon Farrar says in his *Solomon* (London, 1887) that "the taste of a modern worshiper would have been shocked beyond measure by the appearance and smell of the Temple Court. On many occasions it must have been converted into a ghastly *abattoir*, which, but for immense care in purification, would soon have been prolific of pestilence. In that comparatively confined area cattle, large and small, were constantly being slain to the number of many thousands. The floors must literally have swum with blood, and under the blaze of Eastern sunlight, the burning of fat and flesh on the large blazing altar must have been carried on amid heaps of sacrificial foulness."

Solomon's Temple was plundered by Shishak, King of Egypt, thirty years after completion, and finally destroyed by the Chaldeans under Nebuchadnezzar (B.C. 484). It was rebuilt by Zerubbabel (B.C. 520), in a style inferior to the first, and supposed to have been Persian in design. The same ritual was observed, but it became a sort of priestly citadel. Antiochus Epiphanes erected on the altar of burnt offering the Temple of Jupiter Olympus (B.C. 173), but the Maccabees restored the Jewish religion (B.C. 165). Twice ruined in war, the bulwarks were twice rebuilt, and at the time of Pompey's siege (B.C. 63), it was almost an impregnable fortress. Herod laid siege (B.C. 37), and began its reconstruction (B.C. 17). His edifice, with its numerous buildings, was a little city enclosed in its own fortifications and entered by various gates. For the Temple proper the ancient ground plan and dimensions were preserved, and the Oracle remained in the same spot. The Greek-Roman influence was seen in the vast colonnades and cloisters, the eastern one being known as Solomon's Porch, because it rested on the supposed foundation of the original. During the siege of Jerusalem by Titus (A.D. 70), the Temple perished in a conflagration, and, as all traces of it have disappeared, its exact position has for years been one of the most fiercely contested points in Jerusalem topography. The latest results of excavation seem to support Fergusson's theory that it occupied a square of 600 feet at the s.w. angle of the Harâm enclosure, which agrees with Josephus.

Mount Moriah is endeared to Mohammedans and Jews, being revered as the Tomb of Solomon, the place where Abraham offered Isaac, the praying spot of David, Elijah, and the prophets, "the threshing-floor of Araunah" (Chronicles II., iii.), and associated with Mohammed. Here he rested after his miraculous journey from Mecca to Jerusalem, and from it he is thought to have ascended into heaven upon his steed, El-Borak. Sakhra, the Sacred Rock, is said to bear a foot-print of Mohammed and a hand-print of the Angel Gabriel, and beneath it the Ark of the Covenant is now supposed to rest. The famous Basilica called *The Dome of the Rock* (Kubbet es Sakhra), popularly known as the *Mosque of Omar*, is built upon the Sakhra, which rises out of the marble pavement in nearly the centre of Mount Moriah. In *Temple or Tomb* (London, 1880), Sir Charles Warren says the "Sakhra is the traditional site of Solomon's Temple among the Jews, and that all Jewish and Mohammedan writers concur in supposing the Sakhra to have been the Holy of Holies." The construction of the Dome of the Rock, which has been compared in beauty to the Taj Mahal, and of which a good description is contained in Sir Charles Wilson's *Jerusalem: the Holy City* (London, 1889), has been the subject of controversy. It is variously attributed to Omar-ben-al-Khataab, Constantine, Justinian, and the Arabs under Byzantine influence. For accounts of this and the neighboring Mosque el Aksa, see T. Hayter Lewis, *The Holy Places of Jerusalem* (London, 1888); Sir Charles Wilson, *Temple or Tomb* (London, 1880); Comte Melchior de Vogüé, *Églises de la terre sainte* (Paris, 1860); Sepp, *Die Felsenkuppel eine Justinianische Sophienkirche* (Munich, 1882); Procopius, *Buildings of Justinian* (translated by Aubrey Stewart in *Palestine Pilgrims' Text Society*, London, 1886); and Mukad-dari (*Palestine Pilgrims' Text Society*, London, 1886). These buildings and others used by the Knights Templars stand in an enclosed space known as Harâm es Sherif, now the scene of excavations. The work undertaken by the Palestine Exploration Fund has revealed the enormous height of Herod's walls, now supposed to have been reconstructed on

the original masonry; and although these are not entirely uncovered, they seem to justify the measurements of Josephus, until recently considered exaggerated. The literature of the subject is enormous, one of the first important works being by the brothers Pradi, Spanish Jesuits, known as Villapandi, a superbly illustrated folio (Rome, 1596-1604). See Josephus, *History of the Wars of the Jews and Jewish Antiquities*; L. Capina, *Tempio di Gerusalemme* (Rome), and *L'Architettura Antica* (vol. i.); De Vogüé, *Le Temple de Jerusalem* (Paris, 1864); Thrupp, *Antient Jerusalem* (Cambridge, 1855); Fergusson, *Topography of Jerusalem* (London, 1847); do., *The Temples of the Jews* (1878); do., *History of Architecture* (1863-'67); do., *Principles of Beauty in Art* (1849); Lewin, *The Siege of Jerusalem by Titus* (London, 1867); Wilson and Warren, *The Recovery of Jerusalem* (London, 1871); Perrot et Chipiez, *Histoire de l'Art* (Paris, 1887); Charles W. Wilson, *Jerusalem* (London, 1889); Mrs. Margaret Oliphant, *Jerusalem* (London, 1891); E. Robinson and E. Smith, *Biblical Researches in Palestine* (Boston, 1841); Timothy Otis Paine, *Solomon's Temple, or Holy Houses of the Hebrew, Chaldee, Syriac, Samaritan, Septuagint, Coptic, and Itala Scriptures, Josephus, Talmud, and Rabbis* (with plates, Boston and New York, 1885); E. Robins, *Review of Various Theories, etc., respecting Solomon's Temple* (Dryden Press, London, 1886); Banister, *Temples of the Hebrews* (London, 1861); *El-Sinti: History of the Temple from the Arabic*, by Reynolds (London, 1837); Bennett, *Temple of Ezekiel* (London, 1824); Meyer, *Der Tempel Salomons* (Berlin, 1830); Hirt, do. (Berlin, 1809); Bähr, do. (Carlsruhe, 1848); Keil, do. (Dorp, 1839); Rosen, *Der Tempel-Platz des Moria* (Gotha, 1866); *Monographs in Hebrew*, by C. Altschul (Amsterdam, 1724); J. M. Altschul (do., 1782); W. Altschul (Sklov, 1794; Warsaw, 1814); Heller (Prague, 1602); Chefetz (Venice, 1696); Snizler (London, 1825); Leone (Amsterdam, 1660); and *Publications by the Palestine Exploration Fund* of London, notably *The Jerusalem Volume*, by Sir Charles Warren (1884); *History of Jerusalem*, by Walter Besant and E. H. Palmer (1871), and *Thirty Years' Work in the Holy Land*, by Walter Besant (London, 1895).

TEMPLEMORE, a market-t. of the co. of Tipperary, province of Munster, Ireland, is supposed to take its name from a commandery of the knights templars, and is situated on the right bank of the river Suir, 9 m. n. of Thurles. The pop. in 1891 was 2433.

TEMPO (Ital. time), the degree of rapidity with which a piece of music is to be executed. The rhythmical proportions of notes, as indicated by their form, give them only a relative value, and have no reference to the absolute speed with which the composition should be played. Some compositions require, from their character, a quick lively movement; for others, a slower movement is more suitable; and different terms are used to indicate different gradations of movement. Of these the principal, beginning with the slowest, are: *Largo*, broad; *larghetto*, somewhat broad; *lento*, dragging; *grave*, heavy, solemn; *adagio*, slow; *andantino*, moving a little; *andante*, moving; *allegretto*, somewhat lively; *moderato*, moderately quick; *allegro*, lively; *vivace*, with vivacity; *presto*, rapidly; *prestissimo*, with great rapidity. These terms are not always used with the precision that might be wished, and sometimes apply more to the character than to the absolute speed of performance. They are often modified by other qualifying words, as *allegro con brio*, lively and with briskness; *allegro appassionnato*, passionately excited. The *tempo* is indicated with more exactness by a reference to the beat of the metronome (q.v.). Thus, M.M. ♩ = 120, signifies that 120 beats of the metronome, each representing a crochet, are to fill up the space of a minute; M.M. ♪ = 60, that 60 quavers are to be performed in a minute.

While the general rule is, that the time of a movement is to be steady and unvarying, cases often occur where a certain part of a composition has to be taken quicker or slower than the rest; this is indicated by such terms as *più vivo*, more lively; or *ritenuto*, kept back; while a return to the original time is expressed by the words *a tempo*. The performer may be required to proceed from one degree of movement to another, not abruptly, but gradually; the terms used to express this are: *ritasciando*, slackening; *ritardando*, retarding; *calando*, calming down; *stringendo*, pressing on; *accelerando*, gradually increasing speed; with some others.

TEMPO RUBATO (stolen time) is the name given to a mode of performance in which a restless character is imparted by protracting one note beyond its proper duration, and curtailing another, so that the aggregate duration of each measure remains unchanged.

TEMPORAL BONES. See SKULL.

TEMPORAL POWER (OF THE POPE) is a phrase susceptible of two meanings, which are very distinct from each other, and the confusion of which has led to frequent and serious misunderstanding.

I. In one of these senses it means the sovereign power which the pope possessed as ruler of the so-called papal states (q.v.), and which, especially of late years, has been the subject of much controversy. The power which the pope exercised within his own states, although modified in its exercise by his spiritual character, was in substance the same as that of any arbitrary sovereign. The history of its origin and progress, and of the variation of the limits within which it has been acknowledged, is briefly detailed under the head PAPAL STATES. The question as to the necessity or utility of such a power vested in the hands of a spiritual ruler, and even of its lawfulness and its compatibility with his spiritual duties, has been very warmly debated; nor is this controversy of entirely recent origin. Many of the mediæval sectaries put forward the principle of the incompatibility of the spiritual with the temporal power in the same person, not only in relation to the pope, but also as to the baron-bishops or other ecclesiastical

seigneurs of that age. Such were the doctrines of the Vaudois, of Pierre de Bruis, and above all, of Arnold of Brescia. The last-named of these rendered himself specially obnoxious by the activity and even turbulence with which he propagated this view, and the sentence of death under which he suffered was the penalty of rebellion quite as much as of heresy. Through the centuries which followed, the anti-papal controversies turned so entirely upon doctrine, that there was little room for the discussion of this question, and it is a mistake to suppose, as has not unfrequently been done, that it entered in any way into the conflict of Gallican and Ultramontane principles. Even the great Gallican champion, Bossuet, not only admitted the lawfulness of the pope's temporal sovereignty, but contended that it was in some sense necessary to the free exercise of his spiritual power, and to the independence of his ecclesiastical government. It was not until the aggression of the French republic upon Rome, and the annexation of the papal provinces called the Legations to the Cisalpine republic, and afterward to the kingdom of Italy, by Bonaparte, that the controversy assumed any practical interest. During the later conflict between Pius VII. and Napoleon I., the design which the latter entertained of a still further annexation of papal territory was one of the main causes of dispute; and still more recently, after the re-annexation of nearly the same portions of the papal states to the kingdom of Italy, the question once more agitated the entire Catholic world. No formal and authoritative judgment of the Roman church was pronounced regarding it; but a strong and almost unanimous expression of opinion was tendered to the late pope, Pius IX., in the form of letters and addresses from the bishops and others in every part of Catholic Christendom. The tenor of all these is nearly the same. They profess that the possession of temporal sovereignty is no essential part of the privileges of the successor of St. Peter; but they also regard the possession of a sovereignty independent of any particular sovereign, as the means providentially established for the protection of the spiritual independence of the pope, and of the free exercise of his functions as spiritual ruler of the church. The contrary opinion held by some distinguished members of the Roman church, although regarded with great disfavor, was not formally condemned by a doctrinal decision, nor was any action taken on it in the Vatican council. The recent annexation of the city of Rome itself to the kingdom of Italy elicited a still stronger expression. The event is noticed in the article **PAPAL STATES** (q.v.).

II. By the second signification of the phrase "temporal power of the pope" is understood what would more properly be called the claim of the pope, in virtue of his office, to a power over the temporalities of other kings and states.

This power may be of two kinds, *directive* and *coercive*. In the first sense, it is a claim which no Catholic, consistently with his belief of the spiritual supremacy of the pontiff, can be supposed to deny, as it imports nothing more than that the pope, as supreme moral teacher, has power to instruct all members of his church, whether subjects or sovereigns, in the moral duties of their several states.

If the power be regarded as coercive, it is necessary to distinguish the nature of the coercion which may be employed. That coercion may either consist in the threat or infliction of *purely spiritual censures*; or it may involve temporal consequences, such as suspension or deprivation of office, forfeiture of the allegiance of subjects, and even liability to the punishment of death. Considered in the former sense, the claim must be regarded as a natural consequence of the spiritual headship of the church, which is acknowledged by all Catholics; nor can it be denied that the power to compel sovereigns, by purely spiritual censures, to the fulfillment of the moral duties which their state imposes, is a natural concomitant of the spiritual primacy.

But the papal claim to authority over the temporalities of kings has gone far beyond these limits. Since the 10th c. popes have claimed and repeatedly exercised a power of coercing kings, and punishing them when refractory by suspension, by deprivation, and by the transfer of the allegiance of their subjects to another sovereign. This well-known claim has been a subject of controversy in the Roman Catholic church between the Gallican (see **GALLICAN CHURCH**) and Ultramontane (q.v.) schools; and in the Ultramontane school, two different theories have been devised for its explanation. The first and most extreme (which holds the power to be a direct one) supposes that this power was given directly by God to St. Peter and his successors, that the two powers are fore-shown by the "two swords" mentioned in Luke xxii. 38, and that the temporal power is a privilege of the primacy by divine law, equally with the spiritual sovereignty itself. According to the second, or *indirect* theory, the temporal power is not directly of divine institution, but is an indirect though necessary consequence of the spiritual supremacy; and is only given as a means of completing, and, in a corrupt and disorganized state rendering more efficacious, the work which the spiritual supremacy is directly instituted to accomplish. It was in this latter form that the theory of the temporal power was defended by the great champion of Ultramontanism, Cardinal Bellarmine, and the celebrated declaration of the Gallican clergy (*Declaratio Cleri Gallicani*) in 1682 (see **GALLICAN CHURCH**) was directed against it.

A third view of the temporal power, and one which has found many modern defenders, was propounded by the celebrated Fenelon (q. v.). According to Fenelon's theory, which is generally described as the historical theory of the temporal power, the pope does not possess, whether by direct divine appointment, or in virtue of the necessities of his spiritual office, any temporal power whatsoever. But he possesses the

plenitude of that spiritual power which is required for the government of the church, and he is empowered to enforce it by spiritual penalties, and especially by excommunication or deprivation of membership of the church. Now, although excommunication and such other penalties, of their own nature, are purely spiritual, yet the religious sentiment of the medieval period, and the awe with which it regarded the authority of the church, invested these penalties with certain temporal effects. See EXCOMMUNICATION.

The penalty of forfeiture of certain civil rights was attached by the law of England, in the case of private persons, to the spiritual censure of excommunication (q. v.). The same penalty was applied by the laws of other countries to the sovereigns themselves; by the law of Spain in the sixth council of Toledo in 638; that of France, as confessed by Charles the Bald in 859; the law of England, under Edward the Confessor, and the so-called Saxon and Swabian codes of Germany. The last-named codes recognize in the pope, in certain specified cases, the right to excommunicate the emperor himself; and ordain that in case the emperor should remain for twelve months without being absolved from the excommunication, he shall be deposed. In the appeal of the Saxon nobles to the pope against Henry IV., this law is expressly referred to. The contemporary historians, Paul of Bernried, Lambert of Aschaffenburg, Nicholas Roselli, and others, describe it as the ground of the emperor's deposition; and even Henry himself, without denying the force of the law, sought his defense solely in a denial of the charge of heresy which was imputed to him. The same spirit of the age is exhibited in the form of oath taken at the coronation of the sovereign in many countries, especially (although not exclusively) in those whose kings—as Roger of Sicily, Peter III. of Aragon, Guiscard of Naples, Godfrey of Jerusalem, and John of England—had made their kingdoms feudatory to the see of Rome; by which the monarch swore to be the protector and defender of the sovereign pontiff and the holy Roman church in all their necessities and utilities, and to guard and maintain their possessions, honors, and rights.

From these and similar indications of the public feeling of the mediæval time, the advocates of this theory of the temporal power infer that orthodoxy and obedience to the pope, in all essential matters of faith and discipline, were by the consent, express or tacit, of sovereigns and of peoples accepted as a condition of the tenure of supreme civil authority—a condition similar in its character and objects to that which forms the basis of the limitation settlement of the succession to the English crown, to the heirs of the princess Sophia of Hanover, “being Protestant.” Hence they conclude that the function really exercised by the popes in relation to heterodox or scandalously immoral sovereigns, or oppressors of the church and church liberties, was in itself a spiritual one, and that the civil consequences which it entailed of deprivation or deposition arose, not from the church law, but from the expressed or understood international civil law of the age. This notion of the origin and nature of the pope's power over sovereigns and states may be regarded as the view now commonly received, and it may help to a better understanding of some points of the controversy regarding the celebrated Syllabus. It may be added, that this view is not confined to Catholic writers, but is held by Leibnitz, Pfeffel, Eichhorn, Voigt, Frederick Hurter (while still a Protestant), and others.

On the other hand, it is difficult, if not impossible, to reconcile this theory with the language used by the popes themselves in enforcing their claim to temporal authority, and with the arguments upon which they rest that claim. Nor can it be denied that whatever is said of the cases of the exercise of such a power which occurred in the 12th and 13th centuries, the power continued to be claimed and to be exercised down to and even after the reformation, when it would be idle to suppose that any such public understanding, if it had existed in the middle ages, had not been revoked, if not by all, at least by those nations which had revolted from the Roman church.

The history of most of the principal instances of the exercise of this power by the popes, will be found detailed under the separate articles which refer to the particular popes or sovereigns who engaged in the contest of church and state.—See Gosselin's *Pouvoir du Pape au Moyen Age*.

TENACITY (Lat. *tenacitas*, power of holding) is that property of material bodies by which their parts resist a force employed to attempt to separate them. It is the result of the attractive forces exerted by the particles of matter upon one another through the infinitesimally small spaces which are supposed to exist between them; hence it differs in different materials, and even in the same material at different degrees of temperature. The practical bearings of the tenacity of solids (especially of wood and iron) are discussed in the article **STRENGTH OF MATERIALS**; and we shall therefore here only state a few of the conclusions at which Muschenbroek and other experimentalists have arrived regarding the modifications which the tenacity of metals undergoes in consequence of various processes. Forging and wire-drawing increase the tenacity of metals in longitudinal direction. Copper and iron have this property more than doubled, while gold and silver have it more than trebled by these metals being drawn into wire. Mixed metals have usually a greater tenacity than simple ones. See **ALLOY**.

TENAILLE, in fortification (q. v.), a work in low relief, constructed immediately in front of the curtain. It may either have two faces, in a line with the faces of the adjoining bastions, and meeting at the center in a re-entering angle; or three faces, of which two are prolongations of the bastion faces, and one parallel to the curtain. The tenaille

must be low enough for the defenders to be safe from the musketry-fire on one bastion defending a breach in the other bastion. This work protects the ditch, covers the postern from the enemy's view, etc. See *illus.*, FORTIFICATION, vol. VI.

TENANCY AT WILL, in point of law, means an occupation by a person in the character of a tenant, but for no fixed term other than the will or caprice of the landlord or proprietor. In general, courts are averse to assume a tenant to be a tenant at will, if there are materials to satisfy the description of a yearly tenant. Rent is payable, under a tenancy at will, according to the time of occupation, and the tenancy can be determined by either party at any time. But the tenant is not to be prejudiced by the sudden determination of the tenancy, so that if he has sown the lands, he is entitled afterward to re-enter the lands, to reap the crops; and, in like manner, he has a reasonable time to remove his furniture.

TENANCY IN COMMON, in point of law, means a right to hold or occupy lands, or possess chattels, along with another or other persons. In such a case, each has an equal interest; but in the event of the death of either, his share does not go to the survivors, as is the case in joint tenancy (*q. v.*), but to his heirs or executors. Tenancy in common applies to ownership as well as leasehold interests. Though each tenant has as much right to the whole property as the others, yet neither has a definite share set apart to himself exclusively. If one wastes or deals with the property to a greater extent than his share, the others can bring an action against him. Each can at any time compel a severance of the property. The undivided interests held by tenants in common need not be acquired at the same time or by the same title by all the tenants, and they need not be the same in amount. The share of each tenant is subject to his debts, and to dower and courtesy. His power over it is absolute. He may make a conveyance of it, devise it by will, or encumber it by mortgage. In most of the states the common law rule has been so changed by statute that what would be a joint tenancy in England is in this country a tenancy in common; so that persons who take land in undivided shares by will or deed are tenants in common. A tenant in common can always compel partition. See PARTITION.

TENANCY ON SUFFERANCE differs from a tenancy at will in this, that a tenant at will enters on a good title, whereas a tenant on sufferance has no title, and wrongfully continues. Thus, when the term has ended, and the tenant has got notice to quit, but does not, he continues a tenant on sufferance, and may be ejected at any time, unless the landlord elect to treat him as a tenant in continuation of the former lease.

TENANT FOR LIFE, in English law, means one who has not the absolute property, but an interest in the property, which ceases with his own life, or the life of another. An estate for life in lands is classed with freehold estates. Where the estate for life depends on the life of a third person, as it is the interest of the tenant that such third person should live as long as possible, frauds are often committed on the reversioner by misrepresenting the fact of such person being alive; hence, to prevent fraud, the reversioner may insist on the third person being produced, failing which he will be taken to be dead. An estate for life is usually created by deed, but there are two legal estates for life—namely, the widow's estate in dower, and the husband's estate by courtesy on his wife's death. As a general rule, a tenant for life of real estate is entitled to take wood to repair and burn in the mansion of the estate; but he cannot for other purposes fell the trees, nor open mines or pits, though, if these have been already opened, he may carry them on. Sometimes a tenant for life is declared by the deed or will to be tenant without impeachment of waste, in which case he can exercise most of the rights of an absolute owner, except cutting down ornamental timber, or defacing the family mansion. Tenants for life may now apply to the court of chancery for leave to raise money to drain the lands and make improvements. When a tenant for life dies between the usual terms for drawing rent, the rent is apportioned between his executors and the party next entitled. A tenant for life is called, in the law of Scotland, a life-renter. See FEE AND LIFE RENT.

TENANT IN FEE SIMPLE, in English law, is the old feudal description of one who is absolute owner, the fiction being that all were originally tenants of the crown. A tenant in fee simple has a freehold estate of inheritance, which is the highest degree of property known to the law. There is practically no feudal connection with the crown, and he can alienate or devise the property without the leave or sanction of the crown. A tenant in fee simple has an absolute right to the soil and the mines down to the center of the earth, and has a right to build as high as he pleases. If he dies, the estate goes to his heirs, *i. e.*, his heirs general; but he has power to devise it to whom he pleases, subject to certain restrictions, in cases where the donee is a charitable corporation or trustee for charitable purposes. See MORTMAIN. A tenant in fee simple is called, in the law of Scotland, a *fiar* (*q. v.*).

TENANT IN TAIL. See TAIL, ESTATE.

TENANT-RIGHT. This term is used by tenants to denote the various claims of right which they may maintain against their landlords, such as the right of occupancy not subject to removal; and the right to occupy at a rent not subject to increase on the ground of improvements; it being said to be inequitable to make

them pay rent for what they have themselves produced. It is in Ireland that the claims have always had most importance. In Ulster, and in the north of Ireland generally, the equity of them has long been recognized and acted upon. In the south of Ireland, on the other hand, tenant-right was never conceded by the proprietors; while the right of occupancy not subject to removal, has, *de facto*, been enjoyed by the tenants. The non-settlement of the question was long the cause of bitter controversy, and undoubtedly its evil condition was the root of much of the national misery. Owing to the old tenure of land as tribal or clan property, the people of the south of Ireland never received into their minds the notion of "contracting" with any one as the "owner" of land. They had the traditional feeling of being themselves the owners; and so much was this feeling a source of agrarian disturbances, that few Irish "landed proprietors" have ever ventured fully to exercise their rights of property. And nothing was more common in the south than to find that the land had been in the occupancy of the same families from time immemorial without lease or contract of any kind.

By the Land act of 1870 the Ulster tenant-right custom and all corresponding customs received the force of law, and when there was no definite custom, the outgoing tenant became entitled to compensation from the landlord to an amount varying from one to seven years' rent. The Land act (Ireland) of 1881 makes most beneficial changes in the position of Irish tenant farmers. A Land commission or court (with sub-courts throughout the country) was established, to which every tenant may have recourse in order to have a "judicial" rent fixed for a period of 15 years, at the end of which time the tenant may again apply to the court. During the 15 years the tenant cannot be evicted save for the breach of certain conditions, on non-payment of rent, and the rent cannot of course be raised. The tenant's right to sell his tenancy to one person at the best price he can get was recognized; and provision was made for advancing money to tenants willing to purchase their holdings absolutely.

The Irish claim of tenant-right very much resembles that made by the Indian ryots against their zemindars. In India, as in Ireland, until what may be called recent times, land belonged to families or communities, which held themselves to be composed of kindred; but by acts passed by our government, a class of mere tax-collectors have been converted into land-owners, in order to facilitate the collection of the revenue. Hence, there has been in India an agitation very much resembling that which prevailed in the south of Ireland. The ryot claim of tenant-right was made the subject of a suit before the supreme courts of India, when a majority of the judges favored the equitable claim of the ryots. In countries where the people have been trained in notions derived from the Roman or feudal laws, there has been little heard of this species of claim of right, and land has been recognized by the people as being, like other things, a fair subject for contract.

In Scotland and in the north of England farms are almost always let on long leases, and at such rents as are supposed to repay the tenant the capital which he may lay out in improvements; and the common case is, that the landlord binds himself to pay the tenant a stipulated sum as the value of his improvements, provided that these are found at the end of the lease to be of a certain stipulated value. Over England generally, on the other hand, tenancy can be ended by six months' notice on either side, and the evils incidental to this precarious tenure have been obviated or mitigated solely by the honorable conduct of the English proprietors. It is quite common in England to find that the son has succeeded the father as tenant-at will for many generations, often for centuries.

Since the admission of the claim to tenant-right in Ireland, it has been more frequently heard of in the other parts of the United Kingdom, especially in the form of a claim to compensation for permanent or unexhausted improvements made by the tenant. Of the equity of this claim there can be no doubt, and the Agricultural Holdings act of 1883 (see LANDLORD AND TENANT) in some measure recognized the British farmer's right to compensation in such cases. Without this, the law by which the ownership of improvement follows the ownership of land, is in the present condition of things in the highest degree unjust and inexpedient. The tenant's interest in all his improvements ending with his tenancy, he is very unlikely, at least toward the end of his term, to spend anything on the land which will be of benefit to it; and where he is a tenant-at-will, he is entirely without interest to improve it.

TENAS'SERIM, acquired by Britain after the war in 1825, is the third or southernmost division of British Burmah* (q.v.)—the other two divisions comprising the ancient kingdoms of Pegu and Aracan. On Jan. 31, 1862, these three maritime provinces were united under one local administration. Pegu has since been subdivided.

Tenasserim is a narrow line of coast about 500 m. in length, with a varying breadth of from 40 m. at its southern extremity to 80 m.; the latter distance being measured from the sea-shore at the mouth of the Salwen to the range of mountains on the e. that separates Tenasserim from Siam. It extends lengthwise from the southern

*The provinces of British Burmah extend along the eastern shore of the bay of Bengal from the Naf estuary, in about 20° 50' n. lat. to the Pak-chan river, in about 10° 15', with a coast-line of 900 English miles. Their area and population, according to the returns of 1891, are as follows: Aracan, area 14,526 sq. m., pop. 672,000; Pegu, area 9299 sq. m., pop. 1,456,000; Tenasserim, area 46,590 sq. m., pop. 978,000; Irrawadi, 17,542 sq. m., pop. 11,552,000.

border of Pegu in $17^{\circ} 50'$ n. lat. to near the tenth parallel of n. lat., and from $97^{\circ} 30'$ to $99^{\circ} 36'$ e. long., and has a total area of 46,730 sq. miles. Tenasserim is divided into six administrative districts, besides the town of Moulmein: Toungu, area 6,354 sq.m.; Schwe-gyen, 5,567 sq.m.; Salwen, 4,646 sq.m.; Amherst, 15,193 sq.m.; the town of Moulmein, 10 sq.m.; Tavoy, 7,200 sq.m.; and Mergui, 7,760. The principal town is Moulmein, the next in importance being Toungu and Mergui.

Physical Features.—The general aspect of the country is bold and picturesque. The numerous wooded ranges of hills take generally a course from n. to south. The northern part of the country is the most level; the southern portion is little else than a wilderness of thickly-wooded hills, inclosing long and narrow valleys. The soil of the plains is very fertile, and suited to the growth of rice, indigo, cotton, sugar, and vegetables. Tobacco grows chiefly on the banks of rivers in the hills. Only about $\frac{1}{15}$ of the country is under cultivation, and the forests occupy two-thirds of the entire area. The chief rivers are the Salwen, Gyne, Attaran, Yé, Tavoy, and Tenasserim. The Tenasserim, from which the country derives its name, is the most considerable river of the province. The principal ports of Tenasserim are Moulmein (q.v.), Amherst, Tavoy, and Mergui, of which Moulmein is the best. Amherst harbor, at the mouth of the Salwen, affords good anchorage for ships of any draught of water, but is difficult of approach. The Mergui archipelago, lying off the southern coast of Tenasserim, consists of almost innumerable islets, some of which are said to be rich in iron ore; and they are famous for their edible birds' nests. Numerous anchorages are found among the islands. The country possesses vast stores of mineral wealth, which now lie absolutely neglected. Gold-washing has been pursued with success at the head of the Tavoy river. At Kahan, on Mergui island, are rich and accessible tin-mines; and thousands of tons of good clean ore, yielding 75 per cent of the pure metal, could be raised not far from the surface of the ground. A very productive iron ore is obtained from Iron island, between Tavoy and Tiger island. Mergui province furnishes a valuable lead ore, and has extensive fields of coal. Manganese has been found on the Tenasserim river, where it is believed to be very plentiful.

Botany.—The botanical productions of Tenasserim may vie with those of any part of the world. There are more than one hundred different kinds of timber-trees, of which the teak is the most important. The celebrated *Amherstia nobilis* is the most splendid of the many flowering and ornamental trees for which Tenasserim is famous. The palm tribe are in great variety, and Dr. Griffith collected 1700 different species of plants in about 14 months.

The climate of Tenasserim is regulated by the monsoons; and the wet and dry seasons divide the year into two nearly equal parts. The average yearly fall of rain is about 194.28 inches, and this descends during the six rainy months from May to October. The greatest amount of rain ever recorded as having fallen in one day (May 27, 1857) is 12.78 inches; and the gauge for the week registered 40.27 inches (Dr. Walter). While the rains last, the temperature is very uniform, the thermometer ranging between 76° and 82° . The cool season lasts from the cessation of the rains in October, when the north-east monsoon begins, to the middle of February. During that time, the thermometer seldom reaches 90° in the shade, and occasionally falls at low as 56° , and now occurs the greatest thermometric range, which is sometimes as much as 30° in one day. The sun then gradually regains its power, and the heat increases daily till the south-west monsoon again brings clouds and rain. In the hot period, the thermometer at mid-day is not often below 92° in the shade, and not unfrequently stands at 95° .

Commerce.—The principal exports from Tenasserim are teak, timber, and rice. The trade of the province is, however, not on the increase. The first two articles of export mentioned are not continuous from year to year; and we accordingly find that the decrease in the value of trade is owing to the diminished demand for teak timber. Indeed the defective continuity of supply is to some extent a fact also as regards timber. Rice is the most reliable article of commerce.

Inhabitants.—In 1891 the pop. of the Tenasserim districts was as follows: Toungu, 162,000; Schwe-gyen, 199,000; Salwen, 31,000; Amherst, 417,000; Tavoy, 94,000; Mergui, 74,000; total pop. of Tenasserim, 978,000. Most are Burmans proper, but there are other races, as Talaings, or descendants of the ancient Peguans; Karens, a dispersed people, inhabiting secluded mountain districts—among whom Christianity has made some progress, through the labors of American missionaries; Touthoos, Khyengs, Shans, Europeans and their descendants, Chinese and Indians. Throughout Tenasserim and British Burmah generally, inheritance and marriage are regulated by Buddhist law, while at the seaports the English mercantile law and law of contracts are in force, and regulate the decisions of the courts.—*The Natural Productions of Burmah and the Tenasserim Provinces*, by the Rev. F. Mason, A.M. (Moulmein, 1850); *Six Months in British Burmah*, by Christ. T. Winter (Lond., 1858); Phayre, *History of Burma* (1883); Murray, *Handbook for Travellers in India, Ceylon, and Burma* (1895); Yoe, *The Burman, his Life and Notions* (2nd ed., 1896).

TENBY, a small parliamentary and municipal borough, and thriving watering-place, of South Wales, in the county of Pembroke, and 10 m. e. of the town of that name. Its charming situation on a peninsula, overlooking the bay of Caermarthen, its salubrity of climate, and the facilities for bathing which the extensive sands in the vicinity afford,

have made it a popular watering-place. A considerable part of the ancient embattled walls of the town still remains. There are also a handsome church and picturesque ruins of a castle. The season lasts from June till October. Fishing is extensively carried on, and some coal is mined in the vicinity. Pop. '91, 4542, but during the summer the number is greatly increased.

TENCH, *Tinca*, a genus of fishes of the family *cyprinidæ*, of a thick form, with small scales, and a barbel at each side of the mouth, the teeth on the pharynx compressed and club-shaped. The COMMON TENCH (*T. vulgaris*) is an inhabitant of ponds and other stagnant waters in Europe and the north of Asia. It passes the winter in a torpid state, concealed in the mud. It is of a deep yellowish-brown color, more rarely golden or greenish. Instances have occurred of its attaining a length of 3 ft., but a tench of half that length is unusually large. It is very tenacious of life, and, like the carp, can be conveyed to a distance alive in wet moss. It spawns in May and June, depositing its spawn among aquatic plants. The ova are very small and very numerous. The flesh of the tench is soft and insipid, except when it is very well fed, when it becomes delicate and pleasant. It is commonly placed in ponds along with carp; a much smaller number of tench than a carp, however, being deemed sufficient to stock a pond. In Britain, the tench is found only in England, and there sparingly in some of the slow and muddy rivers. It is not improbable that it may have been originally introduced as a pond-fish, although it has long been naturalized. Angling for tench resembles angling for carp. The same kinds of bait are used.

TENCIN, CLAUDINE ALEXANDRINE GUÉRIN DE, 1681-1749; b. Paris; at first a nun; absolved from her vows in 1714. She lived in Paris with her brother, afterward cardinal, where she gained riches out of John Law's schemes. She was the mistress of cardinal Dubois, of the regent, d'Argenson, Bolingbroke, and other eminent men; and was the mother of D'Alembert by the poet Destouches. She took an active part in the Jansenist controversy. She was arrested, but acquitted, in 1726, on the charge of having endeavored to make away with La Fresnay, one of her numerous admirers, who had committed suicide at her house. After her release she became a conspicuous figure in society, and her salon was the rendezvous for fashionable and literary people. She was the friend of Fontenelle, Montesquieu, and other literary men. Among her works are: *Le Siège de Calais*, an historical novel (1739-40); and *Les Malheurs de l'Amour* (1747). See *Œuvres de Mesdames de Fontaines et de Tencin*, edited by Garnier (Paris, 1864).

TENDA, COL DE, a pass over the Maritime Alps. See ALPS.

TENDER, as a legal term, means the formal offer to perform some obligation incumbent on the person tendering. It is more frequently used in reference to the payment of money due. See MONEY. When a tender of the debt is properly made, the legal consequence is this, that if the money is refused, the creditor will have to pay the costs of any action he may bring to recover it, and cannot claim interest afterward. In case such an action is brought, the debtor has nothing to do but to plead that he duly tendered the money, and if he then pay into court the sum which he had formerly tendered, the other party must stop the action, or continue it at his own risk. In order, however, that a tender should have the above effect, it must have been duly made—that is to say, it must have been made without imposing any conditions on the creditor, and at the proper time and place. The tender must be in money, and not by bill of exchange; and the paper money of the U. S. government and the national banks are legal tender for any sum. A formal tender of a larger sum than is due is good, but must not require change to be given, which the creditor is not obliged to find. Nor must any condition be annexed to the tender, not even the condition of giving a regular receipt, though on other grounds, by statute, a person receiving payment is bound to fill up a regular receipt on its being tendered to him, and to sign the same. A tender must, in general, be made to the creditor at the place he has indicated, and it is the duty of the debtor to find out and pay the creditor. With regard to payment of rent, however, it is enough that the tenant be ready to pay the rent on the premises at the time it is due, it being the landlord's duty to send or call for it, for the land is the proper debtor, and that is the place to apply to in the first instance. The silver coins of the United States of smaller denominations than \$1.00 are legal tender in sums not exceeding \$10. The nickel and copper coins are legal tender only to the amount of 25 cts. The silver "trade dollar" is not a legal tender.

TENDER, in naval language, a small vessel appointed for the service of a larger one. Steam gunboats are most commonly employed as tenders.

TEN DON is a term employed in anatomy to designate the white fibrous tissue reaching from the end of a muscle to bone or some other structure which is to serve as a fixed attachment for it, or which it is intended to move. In accordance with their form, tendons have been divided into the three following varieties: (1) *Funicular*, or rope-like, as the long tendon of the biceps muscle of the arm; (2) *Fascicular*, as the short tendon of that muscle, and as the great majority of tendons generally; and (3) *Aponeurotic*, or tendinous expansions, sometimes of considerable extent, and serviceable in strengthening the walls of cavities, as, for example, the tendons of the abdominal muscles.

The tendons commence by separate fascicles from the end of each muscular fiber,

and they similarly terminate by separate fascicles in distinct depressions in the bones, besides being closely incorporated with the periosteum. In some birds, whose tendons are black, the periosteum is black also, from this incorporation. If a tendon is ruptured by an accident, or divided by the surgeon, the two ends, if not too far separated, unite with extreme readiness, by the formation of intervening plastic material, which soon acquires great firmness. So rapidly is this process of repair carried on, that, according to Mr. Paget, a specimen, six days after division, could bear the weight of 25 lbs.; while in another specimen, the new material, at the end of 21 days, bore a weight of 56 lbs. When the interval between the two ends of a tendon exceeds a certain limit, there will be only an imperfect bond of union, and either a partial or total loss of the use of the muscle will result. For details regarding this process of repair, which has an intimate bearing on the treatment of ruptured tendons, the reader is referred to Mr. Paget's admirable *Lectures on Surgical Pathology*.

Among the diseases of tendons, *inflammation* requires especial notice. "Tendons," says Mr. Tatum, in his article upon *Affections of the Muscular System*, "together with their sheaths, are not unfrequently inflamed. Independently of gout and rheumatism, the most frequent cause is a sprain or wrench in the neighborhood of a joint. These injuries are occasionally productive of long-continued wearing pains, assuming much of a rheumatic character, and yield often slowly and unwillingly to the remedies, both local and general, employed in rheumatism."—Holmes's *System of Surgery*, vol. iii. p. 544. In one of the forms of whitlow (q.v.), known as *paronychia gravis*, or *tendinous whitlow*, "the tendons and their sheaths in the finger and hand are the seat of a severe and often most destructive inflammation, which, though often confined to one finger, not unfrequently extends to the hand and arm, attacking not only the tendons and softer parts, but exposing the bones, and disorganizing the joints."—*Op. cit.*, p. 544. It arises from slight punctures or wounds, with or without the inoculation of irritant or poisonous matter, and often without any apparent cause, except a derangement of the general health. It begins with severe and throbbing pain in the palmar surface of a finger, which extends upward along the arm. There is extreme tenderness, and a certain amount of redness and swelling, with great tenseness of the parts. If the inflammation is not checked, suppuration soon ensues, accompanied by much constitutional disturbance. The matter frequently extends among the muscles, and in bad cases occurring in unhealthy persons, the bones and joints became affected in the way already mentioned. In the early stage, free leeching, followed by hot fomentations, may be useful. The hand should be kept elevated, and an active purgative, with low diet, prescribed. If, as is often the case, these measures are unsuccessful, a free incision must be made along the center of the palmar aspect of the finger—an operation which gives extreme relief, by removing the tension, and allowing the escape of blood, even if little or no pus is discharged. A generous diet, stimulants, and tonics, are now advisable; and under this treatment the disease generally yields; although cases occasionally present themselves in which the suppuration produces such results as to render amputation of the arm necessary, or even to cause death. A permanently bent finger, from adhesion of the tendon to its sheath, is a common result in severe cases of whitlow of this kind.

Tendons are not very unfrequently the seat of syphilitic enlargements or tumors. Malignant tumors scarcely ever spring from tendons, but fibrous tumors and small cartilaginous enlargements are often found in tendons.

Rupture of the tendons is an accident which is frequently caused by violent muscular action, especially if, from illness or other causes, the muscles have been for some time in a state of inactivity. The long tendon of the biceps cubiti is very obnoxious to this injury, which, in this case, is more often due to the disorganization caused by chronic rheumatic gout than to mere mechanical violence. The other tendons most frequently ruptured are the tendo Achillis, and the tendons of the rectus femoris and the triceps humeri. When a tendon is ruptured or divided by a surgical operation (tenotomy), "the part which is attached to the muscle is drawn away from the opposite end for about an inch. Blood is poured out between the ends, but much less than in rupture of muscles. The pain is said not to be very great; a considerable shock, however, is felt, as from a blow received on the part, accompanied by cramp of the muscle, and a perfect inability to use the limb; and in rupture of the tendo Achillis, a feeling is described as if the heel were sinking into a hole in the floor."—Holmes's *System of Surgery*, vol. iii. p. 541. The essential point in the treatment of ruptured tendon is to keep the injured part in a state of constant rest and muscular relaxation, so that the separated ends may be approximated as much as possible, and to prevent any violent extension till firm union, by the process of reparation, has been established. The special methods of treating individual cases (as rupture of the tendons of the rectus femoris and the triceps, and of the tendo Achillis) are discussed in Holmes's *System of Surgery*, and other standard works on surgery.

TENEBRÆ (darkness), a service in the Roman Catholic Church appointed for Wednesday, Thursday, and Friday of Holy Week. The name is taken from the opening of the Responsorium following the fifth lesson on Good Friday, *Tenebræ factæ Sunt*. The service consists of sixteen Psalms and a Canticle from the old Testament, sung with their proper Antiphons in fourteen divisions, nine Lessons, nine Responsories, the Canticle, *Benedictus Dominus Deus Israel*, and the Miserere. Most of the service is in

unisonous Plain Chant. At the conclusion of each Psalm and Antiphon one of the fifteen candles in the immense triangular candlestick is extinguished with ceremony. During the singing of the Benedictus the six altar candles are put out one by one. The only light remaining is the candle at the apex of the candlestick. This is removed and carried behind the altar. A solo soprano sings the Antiphon, *Christus factus est pro nobis obediens usque ad mortem*. A silence follows, during which the Paternoster is whispered in secret, and soon after the Miserere begins pianissimo, swelling into a cry for mercy. A prayer is made and the candle is brought from behind the altar.

TENE BRIO. See MEAL-WORM.

TENEDOS (Turk. *Bogdsha-Adassi*), an island belonging to Turkey in the n.e. of the Ægean sea, off the coast of the Troad, and about 17 m. s. of the western entrance to the strait of the Dardanelles. It is about 5 m. long by 2 broad, rocky, but not unproductive, with a pop. of, '88, 4140, who are partly Greeks and partly Turks. The chief t., also Tenedos, or *Bogdsha*, has a trade in wine. Opposite Tenedos, on the coast of Asia Minor, is the bay of Besika.

TENEMENT, in the strict legal sense, includes everything of a permanent nature that may be an object of tenure, whether corporeal or incorporeal. The phrase *liberum tenementum*, or freehold, is thus applicable to offices and rents as well as to real estate. The term tenement took its origin in the feudal system, where all lands were held on condition of pecuniary or military service to a feudal lord; and the real estate or incorporeal hereditament became known as the *holding*, or *tenement*. The common use of the word to denote leased or rented houses is derived from the fact that such property was always occupied by tenants rather than by owners in fee. It is now very generally used to indicate rooms let within a building devoted to that purpose.

TENEMENT HOUSES. A tenement house is legally defined as a house occupied by more than three families, living independently, and doing their own cooking on the premises, or by more than two families on a floor, so living and cooking, and having a common right in the halls, stairways, yards, etc. This definition, however, might be made to cover many apartment-houses or flats: tenement houses, commonly speaking, are the poorest class of apartment-houses; they are generally poorly built, without sufficient accommodations for light and ventilation, and overcrowded; the middle rooms often receive no daylight, and it is no uncommon thing for several families to be crowded into one of these dark and unwholesome rooms. Bad air, want of sunlight, and filthy surroundings work the physical ruin of the wretched tenants, while their mental and moral condition is equally lowered. Attempts to reform the evils of tenement life have been going on for some time in many of the great cities of the world; for not only does the wretched condition of the tenants awake sympathy, but the filthy houses are found to be producers of diseases which menace the health of the entire community. In London, where the evils exist to an alarming extent, an earnest reformer, Miss Octavia Hill, has done excellent work of late years, by gradually educating tenants in some of the worst courts of the city to better habits; and she has been enabled by subscriptions to purchase some of the tenement houses, which under her management have been greatly improved. In the U. S., active reform measures have been lately begun in several of the large cities. Tenement houses were erected in New York first abt. 50 years ago. In Philadelphia, Brooklyn, and a few other large cities the bulk of the population still live in single dwellings, but in many American cities the flat system has been adopted—the result of rapid growth of population and increased value of real estate—and large tenement houses have been built accommodating from one to eight families on a floor. It is estimated that one fourth of the entire pop. of the U. S. now lives in cities, and this proportion is increasing. Earnest efforts were made to better the condition of tenement houses and their inmates in New York, 1879, when public attention was vigorously called to the subject by pulpit and press. In that city there is a greater overcrowding of human beings in comparison to the space occupied than has ever been known in any civilized country. Investigations revealed shocking details of tenement life. The N. Y. sanitary Reform Assoc. was organized, especially for reforming the evils of tenement life; and an act was passed, 1879, limiting the space to be occupied by any tenement house to 65 per cent. of the lot pertaining to it, requiring all bedrooms to have windows with direct light and air, and greatly increasing the power of the board of health to remedy the abuses in such buildings. Two associations were formed to build improved tenement houses; and houses for this purpose can now be erected only after the plans have been approved by the Board of Health. In other cities, notably Boston and Chicago, sweeping reforms have been carried out.

TENERA NI, PIETRO, 1789–1869; studied sculpture with Thorwaldsen and Canova at Rome. Among his more famous works are the "Angel of the Last Judgment;" the sarcophagus of Pius VIII. for St. Peter's; "Christ on the Cross," at St. Stephen's in Pisa; and "Flora," now owned by Queen Victoria. He was professor at the Academy of St. Luke, and in 1860 director of Roman museums. His works include a large number of groups, single statues and busts, many of which are remarkable for their beauty and lifelike appearance. Besides the works already mentioned, he executed a fine marble relief of the taking from the cross in the Torlonia chapel in the Lateran, and the relief for the tomb of the Countess of Lante.

TENERIFFE, the largest of the Canaries (q. v.).

TENERIFFE, **PEAK OF**, or **PICO DE TEYDE**, a famous dormant volcano, the highest summit in the Canary islands, stands in the s. w. of the island of its own name, and is 12,182 ft. above sea-level. The middle regions of the mountain are covered with forests, the base, as well as the valley and surrounding hills, covered with vineyards of olives and almonds, orange and fig trees; but the upper ridges, and the peak, properly so called, are wild, barren, and rugged in appearance. The peak and its two inferior neighbors—the *Montaña Blanca* and *Chajorra*—rise from a rugged circular plain of lava debris and pumice, 7000 ft. above sea-level, about 8 m. in diameter, and fenced in on all sides by an almost perpendicular wall of rock. From the crevices of these mountains sulphurous vapors are constantly exhaling. The peak can be seen from a distance of upward of 100 m.; but the view from it is generally destroyed by the dense masses of cloud which hang over the surrounding sea at an average elevation of 4,000 to 5,000 ft., the sky above being almost uniformly clear and bright. Mr. Piazza Smyth, in the summer and autumn of 1856, made here a series of experiments for the purpose of ascertaining how far astronomical observation could be improved by eliminating the lower third part of the atmosphere, and with this object observed for two months, first on Guajara (an elevated peak of the rocky wall, 8,903 ft. high), and afterward on Alta-Vista (on the side of the peak, 10,702 ft. high). See *Teneriffe*, by C. Piazza Smyth (London 1858).

TENESMUS (from the Gr. *teinein*, to strain), is the term employed in medicine to designate a straining and painful effort to relieve the bowels when no fecal matter is present in the rectum; the effort being excited by some adjacent source of irritation. All that is got rid of by the straining, which usually occasions more or less descent of the gut, is mucus, frequently stained with blood. Tenesmus is a common symptom in dysentery, irritation of the bladder, stricture of the urethra, etc.

TENIERS, **DAVID**, the elder, a Flemish artist of note, was born at Antwerp in 1582. For some years he was a pupil of Reubens; afterward, he visited Italy, where he studied under Adam Elzheimer, and, on his return, settled in his native city, where he died in 1649. The subjects of Teniers's pencil are, in general, very homely, and often low—the interiors and exteriors of public-houses, smoking-rooms, rustic games, weddings, etc.; but they are executed in the most vividly realistic manner, with such charm of color, and happy ease of composition, that they never fail to excite in the beholder a lively sense of pleasure. Teniers was almost constantly employed during his career as an artist.

TENIERS, **DAVID**, the younger, son of the preceding, was born in Antwerp, Dec. 15, 1610. He received his first lessons in art from his father, and appears to have learned much from study of the works of Adrian Brauer. He early exhibited works surpassing those of his father, and in 1632 was admitted as a master in the guild of St. Luke, where his name was inscribed on its ledger as "Tenier," a signature found on a number of his early paintings. In 1637 he married Anne Breughel, daughter of John (Velvet) Breughel, and in 1644 was chosen by the Common Council of Antwerp to preside over the guild of painters. About this time he was commissioned by the guild of St. George, to paint a picture which is now in the Hermitage Gallery in St. Petersburg—"The Jubilee Meeting of the Civic Guards." Among his many friends and patrons during his lifetime, were the King of Spain, who had, it is said, a whole gallery filled with the works of Teniers, Queen Christina of Sweden, the Prince of Orange, and the Bishop of Ghent, but his special patron was the Austrian Archduke Leopold William, governor of the Spanish Netherlands, who appointed Teniers gentleman of his bed-chamber and keeper of a collection of pictures he was forming. Up to this time Teniers had resided chiefly in the outskirts of Malines, where he had found numberless subjects for his canvases. In 1647 he removed to Brussels, assuming by the archduke's orders the rank and title of "Ayuda de Camara." Continuing his individual work, he also traveled for the archduke, visiting London, among other cities. Leopold's successor, Don John, was equally appreciative of the great artist, and also studied under him. The wife of Teniers died in 1656, and he married Isabella de Fren, the daughter of a councilor at the court of Brabant. Eager to be ranked among the nobility he petitioned the king for advancement to knighthood, Rubens and Van Dyck having already received that honor, but the monarch refused to grant it so long as Teniers continued to sell his work. Failing in this he acquired greater and lasting renown by founding at Antwerp an Academy of Fine Arts, and obtaining for it a royal charter in 1663. Teniers died in Brussels, Apr. 25, 1690; of his children, David, the eldest (d. 1685) attained celebrity, and a daughter Cornelia married an artist of note, John Erasmus Quellin (1634-1715).

Teniers founded no school, and only one of his scholars, Van Tilborgh, was successful as an imitator. He was a very rapid painter and fully 700 of his pictures have been described. They are scattered through the galleries of England and the continent, and include a large picture of resting pilgrims in the National Gallery in London, "Peter Denying his Master," in the Louvre, and several life-sized portraits in the Doria Pamphili Gallery in Rome. He painted marine views and animals, to some extent, but his pictures chiefly represent country life: peasants disposed in cottages or taverns, or enjoy-

ing themselves out of doors, and in open air scenes he excelled, his skies and landscapes being very luminous and beautiful. In etching he was equally facile. The best works in the Archduke Leopold William's collection were reproduced by him with the needle, and more than 500 plates were made from his own paintings. His genius found additional means of expression in some designs for the tapestry looms of Brussels.

TENIMBER ISLANDS. See TIMORLAUT.

TENNANT, DOROTHY. See STANLEY, HENRY M.

TENNANT, WILLIAM, still to be remembered as the author of *Anster Fair*, was born at Anstruther, in Fife, in the year 1784. A cripple almost from his birth, and doomed to propel himself through life on crutches, he betook himself naturally to study, as requiring no exertion of the limbs. In 1799 he went to the neighboring university of St. Andrews where, however, he only remained two years, leaving it to join his brother, a corn-agent, in business. In this his success was indifferent; and in 1812 he was fain to accept the situation of parish school-master at Denino, a small hamlet about 4 m. from St. Andrews, with a salary of £40 a year. The same year, he had published his *Anster Fair*, a poem of much sprightliness and humor, notable as the first attempt to naturalize in our language the gay *ottava rima* of the Italians; by Byron, soon after adopted with such splendid success in his *Beppo* and *Don Juan*. The piece gradually made its way, and in 1814 a highly laudatory notice of it appeared in the *Edinburgh Review*, from the pen of the then omnipotent Jeffrey. In 1816 Mr. Tennant became teacher of a school at Lasswade, near Edinburgh, whence three years afterward, he transferred his services to the academy of Dollar in Clackmannanshire. His attainments as a linguist were extraordinary; and in 1834 he was appointed professor of oriental languages in the university of St. Andrews—a post for which, perhaps, not many men then living had similar qualifications. In connection with his new duties, he published, in 1840, grammars of the Syriac and Chaldee languages. He died Feb. 15, 1848, at his residence near Dollar, where his summers were usually spent. He was one of the most genial and amiable of men. Besides other miscellanies in verse, he gave to the world, in 1822, *The Thane of Fife, a Poem*; in 1823, *Cardinal Beaton, a Tragedy*; and in 1825, *John Balliol, a Drama*. None of these later productions had much success, or did anything to increase the literary reputation which his first work had won for him.

TENNENT, GILBERT, 1703–64; b. Ireland; came to America with his father, 1718, and aided him in an academy in Philadelphia; studied medicine and theology; was ordained pastor of a Presbyterian church in New Brunswick, N. J., 1726, continuing the connection until 1743, though traveling and preaching with Whitefield in New England for several months; founded and became pastor of a church in Philadelphia, with which he remained connected until his death. In 1851 he visited England with president Davies to obtain aid for the college of New Jersey. He published *Lawfulness of Defensive War; Sermons on Important Subjects*.

TENNENT, Sir JAMES EMERSON, LL.D., 1804–69; b. Ireland; educated at Trinity college, Dublin, and called to the bar. He was a member of parliament, 1832–45; secretary to the India board, 1841–45; and civil secretary to the Ceylon colonial government, 1845–50. He was again elected to parliament in 1852, was secretary of the poor law board the same year, and a joint secretary of the board of trade, 1852–67, when he was made a baronet. Under his original name of Emerson (Tennent being added on his coming into the estates of his wife, a daughter of William Tennent), he published *A Picture of Greece in 1825* (1826); *Letters from the Aegean* (1829); and *History of Modern Greece* (1830–45). Among his later works are *Christianity in Ceylon* (1850); *Account of Ceylon* (1859); *Sketches of the Natural History of Ceylon* (1861); and *The Story of the Guns* (1864).

TENNENT, WILLIAM, D.D., 1705–77; b. Ireland; brother of Gilbert; came to America, 1718. While studying theology he was attacked with fever, and fell into a trance, giving no sign of life, except a slight tremor under the left arm, which led the physician to refuse consent to his interment, and the funeral was postponed for three days, when vitality became perceptible. His recovery was slow and painful, for months his memory and mental faculties seemed lost. At length he felt a sudden shock in his head, and by degrees recovered his recollection. He related that at the time of his apparent death he found himself in the midst of wonderful glory, among a multitude singing very sweetly, and that when about to join them some one said to him, "You must go back." At the shock of this announcement he awoke. He was ordained in Freehold, N. J., 1733, and continued as pastor 44 years. He published a few sermons.

TENNESSEE, a central southern state, and the third in order of admission; stretch-
in from lat. 35° to 36° 30' n.; and from long. 81° 37' to 90° 28' w.; bounded on the n. by Kentucky and Virginia; on the e. by North Carolina; on the s. by Georgia, Alabama, and Mississippi; on the w. by Arkansas and Missouri, the Mississippi river separating; greatest length e. to w. about 432 m.; greatest breadth, 109 m.; land area, 41,750 sq. m.; gross area, 42,050 sq. m., or 26,912,000 acres.

HISTORY.—The name of the state is derived from that given by the Indians to the Little Tennessee river—Tannassee. As early as 1754 emigrants from North Carolina entered what is now the eastern part of Tennessee, and in 1776, when the constitution of North

Carolina was framed, the settlements of what was then styled the District of Washington, sent deputies to the legislative body. The union was never a close one. The mother state neglected the remote and exposed villages beyond the mountains, and in 1784 voted to cede that section of her territory to the United States. Indignant at this action, the settlers asserted their independence, formed the state of Frankland, afterwards Franklin, chose John Sevier governor, elected delegates to a legislature which met in 1785 and requested admission to the union on their own responsibility. Both Congress and North Carolina refused to accede to this proposal, and in 1788 the state of Franklin practically came to an end. In 1789 the cession of Tennessee to the general government took place; in 1790, the territory was organized with Kentucky as the territory of the United States, south of the Ohio; in 1794 it was granted a distinct territorial government, and in June, 1796, it was admitted as a state, with Knoxville as its capital. At that time there were no settlements in western Tennessee, and but a few scattered ones in the middle part of the state. But the westward tendency of emigration soon led to encroachment on portions occupied by the Indians, who were finally removed, in 1819, to the Indian territory, and after that year the growth of Tennessee was rapid; from 1812-15 the legislature met at Nashville; from 1815-26 at Murfreesboro, and from 1826 on at Nashville, which was made the permanent capital in 1843.

In Jan., 1861, a proposal to secede from the Union was defeated, but was carried in June by a majority of 57,667, and in ten months' time the state raised 50 regiments for the Confederacy. The union army received 31,092 men from Tennessee, 20,133 of whom were colored, and the federal cause received enthusiastic support in the eastern mountain region. Nearly the whole state was a battle ground during the war. Severe battles took place at Fort Pillow, Stone River, Island Number Ten, Nashville, Chickamauga, Lookout Mountain, Missionary Ridge, Knoxville, Franklin, etc. In April, 1865, the state legislature met in Nashville, ratified the 13th amendment to the United States constitution, and reorganized the state government, and in 1866 the senators and representatives took their places in Congress.

TOPOGRAPHY, GEOLOGY, ETC.—T. for civil purposes is divided into east, west, and middle T., and comprises 8 great natural divisions. On its eastern borders rises, in huge, ridge-like masses and treeless domes, the Appalachian chain, the loftiest peaks of which attain an elevation of more than 6,000 ft. above the sea. This chain is composed of the Iron, Great Smoky, the Unaka and other mountains, and forms one of the natural divisions of T. Adjoining it on the w., and enclosed between them and what is known as the Cumberland table-land, is the valley of east T., one of the most important agricultural regions. Next comes the Cumberland table-land, an elevated plateau 2,000 ft. above the sea and 1000 ft. above the valley of east T. Then, resting against the western edge of the Cumberland table-land and extending to the Tennessee river, with an average elevation of 1000 ft. above the sea, are the highlands, rimlands, or terrace lands. In the center of these is the great central basin, elliptical in shape, and resembling the bed of a drained lake. Its soil is productive of all the crops suited to the latitude, and it is called sometimes the garden of the state. The western valley forms the sixth natural division, which is comparatively narrow, with spurs from the highlands pointing in towards it and here and there running down to the margin of the T. river. The seventh division is a plateau or slope of west T., and differs from all the others in having only a few rocks. Its soil is light, porous, siliceous, and very fertile. The eighth division is the bottom of the Mississippi, a low, flat, alluvial plain, which has a rank luxuriance of vegetable life that is almost tropical.

The Mississippi forms the w. boundary, receiving all other streams. The Cumberland flows for about 250 m. through the northern part, and the Tennessee crosses the state twice. Besides the affluents of the Tennessee (q.v.), the Big Hatchee, Forked Deer, and Obion are important streams. The eastern mountain-border consists mainly of silurian rocks, and in part is believed to be of the azoic age. It affords asbestos, kaolin, and red, green, and other granites. Valuable copper mines are also found in this region, and the foot-hills abound in iron ore, including rich pyrites, limonite, hematite, magnetite, and iron-manganese ores. In the valley of east T. are lithographic shale, dyestone, heavy-spar, millstone, slate, potters' clay, limestone, native blue vitriol, marble, and ores of lead and zinc. Coal-measures occupy about 5,100 sq. m., mainly occupying the Cumberland mountain plateau, from which an annual product of 900,000 tons is usually derived. Middle T. contains petroleum, saltpetre, alum, gypsum, glass-sand, marble, copperas, fictile clay, and iron. In west T. lignite coal is found in abundance, and there are beds of green-sand marl. In the limestone regions are numerous caves, mostly unexplored. Several in the Cumberland Mountains are 100 ft. deep, and miles in extent. A considerable river has been discovered in one at a depth of 400 ft.; another opening perpendicularly into a mountain has never been fathomed. In some of these caves are large deposits of fossil bones of extinct animals. In some localities are seen impressions of the feet of animals in limestone. Tracts of several acres have sunk into caverns 100 ft. deep. In many places are interesting remains of ancient mounds and fortifications, similar to those found in Ohio.

ZOOLOGY AND BOTANY.—The wild animals include the bear, deer, opossum, raccoon,

fox, and squirrel. The forests of the state have a large variety of timber-trees. In the east the white and other pines grow across extensive tracts; in the west the larch, cypress, and cotton-wood, and nearly everywhere may be found the tulip-tree, hickory, magnolia, sweet and black gum, black and white walnut, cherry, pecan, ash, maple, locust, beech, chestnut, and several kinds of oak. The persimmon, paw-paw, crab-apple, plum, fox-grape, haw, whortleberry, gooseberry and strawberry are common.

CLIMATE AND AGRICULTURE.—The general elevation of the state secures it from the oppressive summer heat of the Gulf States, and the winters are in no parts severe. Along a line running e. and w. through the middle of the state the mean temperature is 57° in east Tennessee, 58° in middle, and 59° in west Tennessee. On the southern boundary it is about 1° higher, and on the northern 1° lower. The only sickly region is the swampy part. The average annual rainfall at Memphis is 45.46 ins.

Tennessee has always been a large cotton-producing state, although since the "Less Cotton Convention" of 1891 the acreage has been greatly reduced. Prices, however, have advanced at least 40 per cent., and growers are slowly recovering from the effects of ruinous markets resulting from excessive production. In tobacco, Tennessee ranks next to Kentucky, North Carolina, and Virginia, with a yield of over 35,000,000 lbs. The principal crops, in round numbers, are—corn, 72,000,000 bushels; oats, 7,250,000 bushels; wheat, 7,000,000 bushels; potatoes, 2,150,000 bushels; hay, 500,000 tons; and cotton, 350,000 bales. Hemp, flax, broom-corn, sorghum, and rice are raised in certain localities, and garden vegetables nearly everywhere in abundance. The dairy products exceed annually 16,000,000 lbs. of butter, 120,000,000 lbs. of cheese, and 1,000,000 gallons of milk. Increased attention is being paid to the breeding of fine stock, especially horses. Belle Meade, said to be the largest and most complete establishment of its kind in the world, was founded over a century ago by John Harding. It embraces 5300 acres, including a deer park of 500 acres. The farms cover an area of over 20,000,000 acres, and with buildings and fences represent an investment of more than \$242,000,000. Farm and ranch animals exceed 3,500,000 head in number and \$35,000,000 in value, and are principally swine, cattle, sheep, and horses.

MANUFACTURES, INDUSTRIES, ETC.—The industries of Tennessee are both numerous and profitable. The U. S. census of 1890 reported for the state, 4559 manufacturing establishments employing \$51,475,092 capital and 42,759 persons, paying \$16,899,351 for wages and \$40,463,782 for materials, and having a combined output valued at \$72,355,286. The principal manufactures, according to the value of output, were flour and grist, lumber products, iron and steel, foundry and machine shop products, cotton goods, cotton seed oil and cake, brick and tile, leather, woolen goods, clothing, marble and stone work, and coke. Among other products are cars, carriages, furniture, metallic wares, tar, turpentine, and charcoal. There are copper, milling, and smelting works. Zinc and zinc paints are made at Clinton and Knoxville. The Tennessee marbles are considered the finest in the world, and are found in every variety. Copper is found in Polk county and lead in Bradford, Washington, and Monroe counties. There are over 40 coal mines in operation, yielding an annual output of over 2,500,000 short tons, valued at the mines at over \$2,350,000. The discovery of phosphate rock in Hickman and Lewis cos. has resulted in a new and important industry. In 1895 petroleum oil was struck in Fentress co., and within six months over \$8,000,000 capital was invested in oil plants, and over 400 wells were in operation.

COMMERCE AND TRANSPORTATION.—The state has no direct foreign commerce, although Memphis and Nashville are both river ports of entry. Both cities have very large annual shipments of cotton, tobacco, grain, and general produce. The entire wholesale trade of the state has been estimated at \$300,000,000. The state has over 4000 miles of railroad, more than three-quarters of which belong to local roads. The capital stock of all roads exceeds \$96,000,000; funded debt, \$112,000,000; cost of roads and equipments, \$202,000,000; net earnings, \$2,900,000. The principal roads are the Southern and the Louisville and Nashville, with their numerous branches.

BANKS.—On Oct. 31, 1896, there were 48 national banks, with capital \$8,275,000, and deposits \$14,835,903; 48 state banks, capital \$3,359,602, and deposits \$5,589,527; and 4 stock savings banks, capital \$250,000, and deposits \$1,135,972.

CHURCHES, EDUCATION, ETC.—The principal religious organizations are: Baptist, Christian, Congregational, Protestant Episcopal, Friends, Jewish, Lutheran, Methodist, Presbyterian, Roman Catholic, and United Brethren in Christ,—the Methodist, Baptist, and Presbyterian leading.

The educational interests of the state until 1873 were much neglected. Though there were many higher institutions, the common schools were allowed to go without system or state aid. At that date the legislature passed a general law establishing schools, and made provisions for their maintenance. For general supervision there is a state superintendent of public schools, nominated biennially by the governor and confirmed by the senate; for local supervision, a superintendent for each county is chosen by the county court biennially; and in each district there are three directors, elected by the people for three years, one going out each year. The law requires state and county superintendents to be persons of literary and scientific attainments and of skill and experience in the art of teaching. The public schools are free to all youth of school age (6-21), but separate schools must be maintained for white and colored. The value of public school property is about \$3,000,000; annual expenditure for public schools, \$1,600,000; school popula-

tion, over 625,000: enrollment, 485,000: average daily attendance, 350,000. The principal higher institutions are the university of Tennessee, Knoxville; Vanderbilt university, Fisk university, Roger Williams university, and university of Nashville, all at Nashville; U. S. Grant university, Chattanooga; Cumberland university, Lebanon; university of the South, Sewanee; and the Southwestern Presbyterian university, Clarksville. The charitable institutions include asylums for the insane at Knoxville, Nashville, and Bolivar; institution for the deaf and dumb, Knoxville; institution for the blind, Nashville; industrial school, Nashville; and a home for confederate soldiers, near Nashville.

GOVERNMENT, ETC.—The capital is Nashville. The constitution provides that every male citizen 21 years old, who has resided in the state one year and co. six months, shall be entitled to vote. The executive power is vested in a governor, who is chosen every two years (salary, \$4000); a secretary of state, elected by a joint vote of a general assembly every four years; a treasurer and comptroller of the treasury, elected in the same manner every two years; an attorney-general, appointed by the supreme court judges every six years; and a state superintendent of schools, nominated by the governor and confirmed by the senate every two years. The house of representatives has 99 members and the senate 33, who are elected for two years. The judicial power is vested in a supreme court of five judges, elected for eight years, with salary of \$4000 each, and in the usual minor courts.

The legal and only rate of interest allowed is 6 per cent.; the penalty for usury is forfeiture of excess of interest. Outside of incorporated cities it is unlawful to sell intoxicating beverages within four miles of an incorporated institution of learning.

The electoral votes have been cast as follows: 1796, Jefferson and Burr, 3; 1800, Jefferson and Burr, 3; 1804, Jefferson and Clinton, 5; 1808, Madison and Clinton, 5; 1812, Madison and Gerry, 8; 1816, Monroe and Tompkins, 8; 1820, Monroe and Tompkins, 7; 1824, Jackson and Calhoun, 11; 1828, Jackson and Calhoun, 11; 1832, Jackson and Van Buren, 15; 1836, White and Tyler, 15; 1840, Harrison and Tyler, 15; 1844, Clay and Frelinghuysen, 13; 1848, Taylor and Fillmore, 13; 1852, Scott and Graham, 12; 1856, Buchanan and Breckenridge, 12; 1860, Bell and Everett, 12; 1868, Grant and Colfax, 10; 1872, Greeley and Brown, 12; 1876, Tilden and Hendricks, 12; 1880, Hancock and English, 12; 1884, Cleveland and Hendricks, 12; 1888, Cleveland and Thurman, 12; 1892, Cleveland and Stevenson, 12; 1896, Bryan and Sewall, 12.

The funded state debt, Jan. 1, 1890, was \$14,110,900; unfunded, \$2,239,000; amount raised by taxation, 1890, \$1,295,000; amount of taxable property as assessed, \$347,508,000; rate state tax on \$100, 30 cts.; receipts for the year ending Dec. 19, 1889, \$2,093,000; expenditures, \$2,029,000. The outstanding new settlement debt, all interest-bearing, in 1897, was \$15,702,800; estimated amount of bonds then fundable, \$940,000; total assessed property valuation (1896), \$312,472,633.

POPULATION.—In 1790, 35,891—3417 slave, 361 free col'd; 1820, 422,771—80,107 slave, 2737 free col'd; 1840, 829,210—183,059 slave, 5524 free col'd; 1860, 1,109,801—275,719 slave, 7300 free col'd; 1880, 1,542,359—403,343 col'd; foreign born, 16,702; male, 769,277; female, 773,082; dwellings, 276,734; families, 286,539; persons to sq. m., 36.94; engaged in agriculture, 294,153; rank of state, 12th in pop., and 18th in value home manufactures; population, 1890, 1,767,518. There are 96 cos.; for pop., 1890, see Census Tables, Vol. XV. The largest cities, 1890, were Nashville, 76,168; Memphis, 64,495; Chattanooga, 29,100; Knoxville, 22,535.

See Ramsey's *Annals of Tennessee to the End of the Eighteenth Century* (Phila., 1853); Phelan's *History of Tennessee* (1888); Putnam's *History of Middle Tennessee* (Nashville, 1859); May's *Pioneers of Nashville and of Tennessee* (Nashville, 1880); Kirke's *The Rear Guard of the Revolution* (N. Y., 1886) and *John Sevier* (N. Y., 1887); Safford's *Geology of Tennessee* (1869); Killebrew's *The Resources of Tennessee* (Nashville, 1874).

TENNESSEE, a river of the United States, the largest tributary of the Ohio, has its origin in the union of the Clinch and Holston, which rise in the Alleghany Mountains of south-western Virginia, and, flowing s.w. in two parallel valleys, unite at Kingston in the w. of Tennessee state. The river flows still s.w. in the Alleghany valley, entering Alabama close by the n.w. corner of Georgia, whence it flows 60 miles further in the same course, then, turning to the w.n.w., re-enters Tennessee at the n.e. corner of Mississippi, flows northwardly across the state, then n.w. across Kentucky to its confluence with the Ohio at Paducah; length 800 miles, or, from the source of the Holston, 1100. Its chief branches are the Sequatchie, Paint Rock, Flint, Duck, North Branch, Hiawasse, Big Sandy, and Clark's. It is navigable 259 miles to Mussel Shoals—a series of broad shallow rapids—and 500 miles above. The river falls about 2000 ft. during its course. Chief towns, Florence and Decatur in Alabama; and Chattanooga, Tennessee.

TENNEY, in heraldry, orange color, one of the tinctures enumerated by heralds, but not of frequent occurrence in coat-armor. It is indicated in engravings by lines in bend sinister, crossed by other barways.

TENNEY, SAMUEL, 1748–1816; b. Mass.; graduated at Harvard, 1772; began practice as a physician in Exeter, N. H.; became a surgeon in the revolutionary army, and was present at the battles of Saratoga and Yorktown. From 1800 to 1807 he was a member of congress. He was one of the first members of the American academy of arts and sciences, and published many scientific treatises and political essays.

TENNEY, SANBORN, 1827–77; b. N. H.; educated at Amherst college, and studied natural history with Agassiz. He was for some years a lecturer on natural history,

of which he became professor in Vassar college at its foundation. He was called to a similar position at Williams college in 1868. Among his publications are: *Geology for Teachers, Classes, and Private Students; a Manual of Geology; Natural History Tablets; and Elements of Zoology.*

TENNEY, WILLIAM JEWETT, b. Newport, R. I.; 1814-83; a graduate of Yale college, 1832: He was co-editor of the *Journal of Commerce*, of the New York *Evening Post*, and editor of the *Mining Magazine*. He was one of the editors of Appleton's *Annual Cyclopædia*. He also edited an illustrated edition of *The Queens of England*, and prepared *The Military and Naval History of the Rebellion in the United States* (1865). He was at one time collector of the port of Elizabeth, N. J.

TENNIEL, Sir JOHN, English artist, born in London in 1820, and educated at Kensington. At an early age he manifested a marked taste for art, and may be said to have been entirely self-taught. In 1845 he was a successful candidate in a cartoon competition in Westminster hall, and in 1851 joined the staff of *Punch*, with which paper he has ever since been connected. His artistic work includes a fresco in the palace at Westminster, and many paintings, chiefly for private collections, besides numerous illustrations of Christmas and other books, such as *Æsop's Fables*, *Lalla Rookh*, *The Ingoldsby Legends*, *Alice's Adventures in Wonderland*, and its sequel *Through the Looking-glass*. He has been for many years a member of the Royal Institute of Painters in Water Colors, and was knighted in 1893.

TENNIS, a game of great antiquity, belongs to the class of ball-games, and finds its analogies in the *sphairistikos* of the Greeks, and the *pila* of the Romans. Under the name of *paume*, a name given to it from the ball being at that time struck with the palm of the hand, it is noticed in the Arthurian romances, and in the earlier records of the dark ages. In the 15th c. it was in great vogue in France among all classes, from the monarch to the meanest of his subjects; and about this time the use of a heavy glove to protect the hand in striking the ball was introduced, and a further improvement was subsequently effected by the adoption of the *racket*. The game in England kept pace with its progress in France, and, during the 16th, 17th, and 18th centuries, was generally practiced under the name of *tennis*. Many modifications have been introduced, but the legitimate descendant of the *paume* and tennis of former days is the present game of rackets. (See **LAWN TENNIS**). "Rackets" is played in a court 96 or 97 ft. long, by 33 or 34 feet wide, and surrounded by walls sufficiently high to prevent the balls from being lost. The players are either two in number, or four, divided into two parties. The player or party "in" serves the ball against the head-wall of the court, so as to rebound over a line drawn at a certain distance; it is returned by means of the racket by the player or party "out," who must make it rebound from the wall to the other side of the line; and the game is thus carried on till one player fails to strike the ball or cause it to rebound properly. If the player "in" fails, he changes places with the player "out;" if the latter fails, the former scores a point. The part of the court on which the player or party in is placed is called the "service" side; the other the "hazard" side. A similar game played without the racket is called *jives*, *hand-tennis*, or *hand-ball*. See **LAWN TENNIS**.

TENNYSON, ALFRED, first baron, b. in 1809 at Somersby, in Lincolnshire, of which parish his father was rector. He was the third of a large family, several other members of which shared with him in some measure the genius which has won for him undisputed rank as the first English poet of his time. Very early the bent of nature became obvious; and in 1827 Tennyson, along with his brother Charles, issued a small volume, entitled *Poems, by Two Brothers*, of which almost nothing has been preserved. Having gone to complete his education at Trinity college, Cambridge, he gained in 1829 the chancellor's medal by a poem in blank verse, entitled *Timbuctoo*, in which there is plainly to be traced some impress of his peculiar genius. His literary career, however, may properly be said to date from 1830, in which year a volume appeared of *Poems, chiefly Lyrical*, by Alfred Tennyson. It was not received with great favor by the public; but amid much that was weak and immature, it contained pieces which in no indistinct manner announced the advent of a true poet. In a notice of the book by prof. Wilson, in *Blackwood's Magazine*, the promise of the young writer was recognised in sufficiently express terms. The praise was, however, not unmixed with censure, which, though it seemed on the whole judicious, did not commend itself as such to the poet, who retaliated on "crusty Christopher" in his next volume, published in 1832. This consisted of a selection of poems from the previous one, carefully retouched by the writer, with the addition of pieces produced in the interval, many of which have scarcely been surpassed in beauty by anything he has since produced. Onward from this time the reputation of the writer slowly but surely extended itself; and the publication, in 1842, of *Poems, by Alfred Tennyson*, in two volumes, raised him to the position of absolute supremacy which he has ever since continued to occupy by almost universal consent. In 1847 appeared *The Princess, a Medley*; and in 1850 the series of elegies entitled *In Memoriam, A. H.*, a tribute of affection to the memory of Arthur Hallam, a son of the eminent historian, and the chosen friend of the poet in his earlier years at Cambridge. On the death of Wordsworth, in 1850, Tennyson succeeded him as poet-laureate, in which capacity he issued, in 1852, his *Ode on the Death of the Duke of Wellington*. In 1855 appeared *Maud, and other Poems*. The immediate reception of this little volume was not enthusiastic. While many of its lyrics instantly caught

the public ear, *Maud*, as a whole, at first rather puzzled the critics, and was little better than "caviare to the general;" and though it has since risen in estimation, the subtle and recondite art exhibited in the structure of the poem is probably even now appreciated by only a few of its admirers. But for any little falling off in Tennyson's popularity on this occasion, a noble *amende* was made him on his next appearance. *The Idylls of the King*, published in 1859, were everywhere received with enthusiasm. With scarce a whisper of dissent, this work at once took rank as one of the noblest poems in our language. It was followed in 1864 by a volume, containing *Enoch Arden*, one of his most finished and successful works; *Aylmer's Field*; a short piece, *Tithonus*, consummate in its beauty and finish; and a few other poems of a somewhat less elaborate character; one of which, however, *The Northern Farmer*, written in the Lincolnshire dialect, is singularly striking. Since then Tennyson has given us several new *Idylls*, which may be considered to complete his handling of the Arthurian romance: *The Holy Grail* and *Pelleas and Ettarre* (1869); and *Gareth and Lynette*, and *The Tournament* (1872). *The Window, or Songs of the Wrens*, appeared in 1870; *The Lover's Tale*, in 1879; *Ballads*, etc., in 1880. *Queen Mary*, a drama, published 1875, was followed by *Harold*, also a play, in 1876. *The Falcon* was acted in 1879; *The Cup*, in 1881; *The Promise of May*, in 1882; *Becket*, in 1884, and *The Foresters* (1892). The last two have been successfully put on the stage both in America and in England. The collected editions of Tennyson's works (since 1872) arrange the various *Idylls of the King* in the order, not of their publication, but of their proper sequence in the legend of Arthur, and enable the reader to appreciate the beauty and significance of the ideal story. Tennyson lived for the most part a retired life in the Isle of Wight, not much caring to cultivate society, but greatly beloved by his friends. He was made a baron, 1883; pub. *Tiresias* (1885); *Demeter* (1889).

It is not an easy matter to criticise the poetry of Tennyson dispassionately, so deeply is one apt to become enamored of its beauties. His verse is the most faultless in our language, both as regards the music of its flow and the art displayed in the choice of words. Nowhere in literature is the *callida junctura verborum* so wondrously seen. As a painter, no modern poet has equaled him. But it is neither to his color nor to his music alone that he owes his great popularity. His *virtue* as a poet doubtless lies in these things; but the pleasure which his poetry gives springs largely from the cordial interest he displays in the life and pursuits of men, in his capacity for apprehending their higher and more beautiful aspirations, and in a certain pervasive purity and strength of spiritual feeling. Lord Tennyson died Oct. 6, 1892. His widow, Lady Emily Tennyson, died Aug. 10, 1896. See Van Dyke, *The Poetry of Tennyson* (1889); Collins, *Illustrations of Tennyson* (1891); Ritchie, *Records of Tennyson* (1892); Stopford Brooke, *Tennyson* (1894), and the *Memoirs* by the poet's son, Baron Hallam Tennyson.

TENNYSON, Baron HALLAM, the eldest son of Baron Alfred Tennyson, was born at Twickenham in 1852, received his education at Trinity college, Cambridge. He published in 1897 *Alfred Lord Tennyson, a Memoir*. He has also edited and wrote (1880) a memoir for a volume of sonnets by his uncle, Charles Tennyson Turner, and has translated from the Saxon a poem, *Brunanbush*, later done into English verse by his father.

TENON, in carpentry, the square end of a timber, reduced about one-third its thickness, to fit the mortise or socket in another timber, so as to join the two.

TENOR, in music, one of the four classes into which voices are divided in respect of their compass. It is the higher adult male voice. Music for tenor voices is most properly written on the tenor or C clef, in which its principal tones come within the staff; but the treble clef is occasionally used, with the notes written an octave above their true pitch.

TENOTOMY, or the division of tendons, is a comparatively recent surgical operation, whose object is to relieve some variety of deformity by severing a permanently contracted muscle at its tendinous portion. The invention of subcutaneous tenotomy is due to Stromeyer (1831), and a lucid account of the history of this operation is given by Dr. Little in his *Treatise on Club-foot and Analogous Deformities* (Lond. 1839). The various kinds of knives that have been devised for severing tendons are termed *tenotomes*. The affections in which tenotomy is advantageously employed are club-foot, contractions of the upper extremity from spasm and paralysis, deformity from diseases of the palmar fascia, torticollis or wry-neck, ankylosis of the knee and other articulations, and squinting.

TENREC, or **TANREC**, *Centetes*, a genus of mammalia, nearly allied to moles and hedgehogs, usually ranked in the family *erinaceida*. The tenrecs are incapable of rolling themselves up like hedgehogs. They are nocturnal animals, natives of Madagascar and the Mascarene isles. Three species are known. They are remarkable for spending the hottest part of the year in a dormant state, as some animals in arctic regions spend the winter. Their flesh has a very peculiar flavor, but is acceptable to the natives of Madagascar.

TENSAS, a parish in n.e. Louisiana, lying on the Mississippi; drained by Tensas river and Macon bayou; 610 sq.m.: pop. '90, 16,647, chiefly of American birth; mostly colored. Surface low, level, and fertile; corn, cotton, and sweet potatoes are the staples. Parish seat, St. Joseph.

TENSE (Fr. *temps*, from Lat. *tempus*, time), in grammar, designates a set of changes which verbs undergo in order to mark the time of the action. See CONJUGATION.

TENT (Lat. *tentorium*, from *tentus*, stretched). Without speculating on the relative priority of tents and other forms of human dwellings, it is safe to assume, that among nomadic tribes, some shelter, easily framed and portable, must have been felt to be a primary necessity. The skins of animals, or the larger kinds of foliage, would form the earliest coverings, for which textile fabrics would be substituted as civilization advanced. In the book of Genesis, the patriarchs, Noah, Abraham, Lot, Isaac, Jacob, are represented as dwelling in tents, probably much the same as the modern Arab tents, which are large structures, very rude in form, covering a considerable space of ground, but of small height. Among the Nineveh sculptures is a representation of the tent of king Sennacherib, which, like modern tents, was supported by ropes: numerous tents of the officers and common people are likewise shown.

The early Greek, and afterward the Macedonian tents were small coverings of skins, under each of which two soldiers slept. Alexander the great is said to have had a pavilion of extraordinary magnificence. Its roof, one mass of gilded embroidery, was sustained by eight pillars covered with gold. In the center, was the royal throne; and 100 beds could be made up within the temporary edifice.

The Roman soldiers seem to have used two sorts of tents—one, a tent proper, of canvas or some analogous material, and constructed with two solid upright poles, and a roof-piece between them; the other, more resembling a light hut, of a wooden skeleton, covered by bark, hides, mud, straw, or any material which afforded warmth. Of these tents, the poles of the first would have been too cumbrous for carriage, and were probably cut afresh at each halting-place; the latter was evidently unsuited to removal, and was most likely only erected for winter-quarters, or a long sojourn. The Roman tent held 10 soldiers, with their *decanus*, or corporal.

In Persia, there are many tribes who pass their whole time in tents, which, naturally, they have brought to considerable perfection. They make them nearly hemispherical, with a wooden framework, and covered with felt, while worked hangings close the aperture. This felt admits of the exhibition of much taste in its decoration.

The Chinese lower orders live much in tents. They are ordinarily of matting. These people are clever in their construction, and make them of great size, and with considerable comfort.

Modern military tents are all made of linen or cotton canvas, supported by one or more poles according to shape, and held extended by pegs driven into the ground. British tents comprise the hospital-marquee, a large oblong tent with high side-walls; and the round-tent, or bell-tent, for troops. The latter is 12 ft. 6 in. in diameter, 10 ft. 4 in. high, weighing, with all its appurtenances, 68 lbs., and giving sleeping accommodation to 16 men; the appurtenances comprise 2 mallets, 50 pins, 20 ropes, 20 loops, and 2 long ropes, for use in storms in giving additional firmness round the central pole. In modern tents, there is a low side-wall of canvas, to give greater room inside. These tents are said to be comfortable and moderately healthy, if floored with tarpaulin, vulcanized india-rubber, or other waterproof material. The great drawback is the tendency to blow over. To obviate this, and the inconvenience arising from the conical shape, maj. Rhodes, a British officer, invented some years ago a new tent, which has found much favor both in this and in other countries. He does away with the central pole, and has a circular frame, hinging in the center like the ribs of an umbrella, over which the canvas is stretched. It is claimed for this tent, that it is more roomy than the regulation-tent, in proportion to its weight, is better ventilated, and possesses far greater stability.

TENTACULITES, a genus of obscure annulated tapering shells, found abundantly in some strata of silurian age. They are generally referred to annelids, but the structure of the shell seems to exhibit greater affinities to recent pteropodous mollusks.

TENTERDEN, a municipal borough and market-t. in the Weald of Kent, 18 m. s.s.c. of Maidstone. The church, which contains portions of early English, is surmounted by a massive and lofty perpendicular tower. Tradition asserts that a quantity of stones, which had been got together for the purpose of strengthening the sea-wall of the Goodwin Sands, were employed in the building of this tower, and that when the next storm came, the district of Goodwin Sands, which had formerly belonged to the mainland, was submerged. Thus arose the popular saying, that "Tenterden steeple was the cause of the Goodwin sands." Pop. '81, 3620; '91, 3429.

TENTERDEN, CHARLES ABBOTT, Lord, a distinguished English lawyer, was born at Canterbury, on Oct. 7, 1762. He was the son of a hairdresser. Being admitted on the foundation of the king's school connected with the cathedral, he distinguished himself by perseverance and extreme accuracy. A small exhibition in the gift of the chapter enabled him to proceed to Oxford, where, in 1781, he was elected scholar of Corpus Christi college; and a few years later he obtained what were then the chief distinctions at the university, the chancellor's two gold medals, one being for English, and the other for Latin composition. In due time he became a fellow of his college. After being a student of the Inner Temple in 1795, he was called to the bar. He joined the Oxford circuit; and in spite of a husky voice, a leaden and unmeaning countenance, and painfully timid manners, his great activity of mind, good taste, scholarship, scientific and legal knowledge, were soon appreciated, so that he rapidly acquired a large business. He

published, in 1802, his treatise *On Merchant Ships and Seamen*, in all respects the best written book which had till then appeared on one department of English law. It had the effect of increasing his employment in the more lucrative mercantile causes; and in 1807, it appears from his income-tax return that his fees amounted to upward of £8,000. In 1816 he accepted a puisne judgeship in the court of common pleas; and in 1818 he was knighted, and chosen to succeed lord Ellenborough as chief-justice of the king's bench. As a judge, his most marked characteristic was his evident impartiality and freedom from bias. The comparative leisure he enjoyed on the bench he spent in reading the classics and in the study of botany. He was, in 1827, raised to the peerage. In the house of lords he was the most influential speaker against the Catholic relief bill; and in his last speech he made a vow that if the reform bill, that "appalling bill," passed, he would never again take his seat as a peer. The success of the measure, it is believed, affected his health. He was seized with a violent attack of inflammation in Nov., 1832, when presiding at the trial of the mayor of Bristol for misconduct during the riots, and he died there on the 4th of that month.

TEN THOUSAND, RETREAT OF THE. After the battle of Cunaxa and the death of Cyrus, in the expedition of the latter against his elder brother Artaxerxes, the Greek army being in great straits chose Xenophon as one of their leaders, and by his firmness and prudence were conducted back to Greece after enduring many hardships and fierce warfare. The story is told by Xenophon himself in his *Anabasis, or Retreat of the Ten Thousand*, (see CYRUS and XENOPHON). The entire distance, going and coming was 1155 parasangs, or over 4,000 English m., and the time occupied in the retreat was 8 months. The course was through Media, across the Carduchi range, through Armenia and across the Euphrates, and then through the countries of the Taochi, Chalybes, Macrones, and Colchians, terminating in the Greek colony of Trapezus, on the Euxine sea.

TENUIROSTRÉS, a tribe or sub-order of birds, of the order *insessores*, characterized by a lengthened slender bill, which is sometimes straight, sometimes curved. Some of them feed on insects, some chiefly on the honey of flowers. To this tribe belong the creepers (*certhiadae*), sun-birds (*cinnyridae*), humming-birds (*trochilidae*), and hoopoes (*upupidae*).

TENURE OF LAND, in England, was an accompaniment or immediate consequence of the feudal system (q.v.) established during the middle ages throughout the greater part of Europe. Feuds were introduced by the barbarous tribes who poured themselves into the Roman empire during the 4th, 5th, and 6th centuries. The chief feature of feuds was, that the lands of the conquered country were parceled out to the leaders, on the condition of bearing arms whenever the sovereign required them. The relation thus created between sovereign and vassal was called a feud. The grantee held his lands at first for life only, but gradually it was developed into a hereditary character, and also into one which admitted of subinfeudation, i.e., the parceling out of the feudal land among vassals of the head vassal, who was the lord of his own vassals. This kind of relation between lord and vassal gradually was extended to all kinds of land, for the owners of allodial land voluntarily surrendered their land to some lord, so as to have the same advantages. The vassal did homage to the lord, and took the oath of fealty. Besides these characteristics, the holding came to be attended with the following incidents. 1. An aid, which was a payment granted to help the lord in his necessities. 2. A relief was a tribute paid by a new tenant on succeeding to his predecessor. 3. A fine was paid by a tenant to the lord on alienating the lands to a purchaser. 4. An escheat or forfeiture was the reverting of the estate to the lord when there was a failure of heirs or some violation of duty on the part of the vassal. The feudal system was extended to England by the Norman barons soon after the conquest, with the concurrence of William I., much to the dislike of the Saxons, whose grievances grew until they found vent in Magna Charta, which was in fact an attempt to restore their earlier constitution. The chief fiction, however, of a relation between the crown and the holders of land was not got rid of. The crown was nominally the lord paramount, and there were intermediate lords called mesne lords, of whom the tenants held. Gradually, the kinds of tenure were classed under free and base services—the former being those which a free-man might perform, as serving in war, or paying a sum of money; the latter, such as a peasant might perform, such as ploughing the lord's land, etc. These were afterward further distinguished according to the certainty or uncertainty of the extended service to be performed. Ultimately, the tenures were classed as three. 1. *Knight-service*, or chivalry, i.e., holding on condition of serving in the war, and taking the oath of fealty. This was accompanied by the incidents of descent, wardship (or guardianship of the knight's heir by the lord), marriage (i.e., the lord's right to give the knight's infant in marriage), aids, reliefs, primer seisin (i.e., one year's profits from an heir on his succession), fine, escheat, and forfeiture. These incidents gradually grew irksome. James I. proposed to commute knight-service into an annual fee-farm rent; but this not being done, the statute of 12 Ch. II. c. 24 swept the whole away, and converted it into free socage. 2. *Free socage* was a tenure by some certain and determinate service, as by paying a small fixed rent, or ploughing the lord's lands for a fixed number of days. The incidents were rather less burdensome than those of knight-service, being descent, wardship, marriage,

and reliefs, primer seisin, fines, escheat, and forfeiture. These incidents were all abolished by the above statute of 12 Ch. II. c. 24, and the tenure of free socage is now generally known as freehold. 3. *Villeinage service*, or copyhold (q.v.) tenure, which still exists nearly in its original state. The result is, that in England at the present day the two tenures are freehold and copyhold. The leading characteristic of freehold is, that practically the feudal relation between the crown and the holder is cut off, and the holder is entirely his own lord and master, can sell the estate, devise it by will, give it away, and do what he likes with it free from any interference or payment to the crown. As to copyhold, the feudal relation is kept up to a certain extent between the lord and the copyhold tenants, who must in form pay rents more or less nominal, and fines and heriots (q.v.) to the lord on alienating the lands or succeeding thereto. Yet, practically, the copyholder does not materially differ from a freeholder except that he is liable to these petty and harassing acknowledgments toward a stranger; and by recent statutes, he can compel the lord of the manor to commute these fines and incidents, and convert the tenure into freehold.

In Ireland the tenure of land is almost identical with that in England.

As to Scotland there is a marked difference between the tenure of lands there and the tenure in England. At the present day the feudal system prevails to a great extent, resembling in many respects the English copyhold tenure. Every piece of land there has generally its lord or superior and its vassal, that is say, the vassal has the *dominium utile*, or actual enjoyment, while the superior has a kind of superior interest, or *dominium directum*, which consists in his drawing a rent called a feu-duty, which the vassal is bound to pay, or to forfeit the land. On each alienation or death of the vassal, there must be certain forms superadded, implying a consent or recognition by the superior, and certain casualties or additional payments must be made on such occasions. Recent statutes have tended to extinguish several of these superfluous forms, and make the vassal more independent. But a great many remain unaltered. And not only is there this feudal relation between the crown and its vassals, but these may subdivide the property and create intermediate estates without limit.

TEOCALLI (House of God), the name given to the temples of the aborigines of Mexico, of which many still remain in a more or less perfect state. They were built in the form of four-sided pyramids, and consisted for the most part of two, three, or more stories or terraces, with the temple, properly so called, placed on a platform on the summit. The largest and most celebrated is the pyramid of Cholula, measuring 1440 ft. each way, and 177 in height; it is much defaced, and the temple on its summit has been removed. The teocallis in Yucatan are in far better preservation; they are not generally built in terraces, but rise at an angle of 45° to the level of the platform, with an unbroken series of steps from base to summit. The temples on their summit are sometimes ornamented with bas-reliefs in stucco and hieroglyphic tablets, and the roof is formed by courses of stone approaching each other, and furnished with projections like dormer windows. Not unlike the teocallis are the palaces of the Aztec kings or chiefs, which differ from them in having the pyramid smaller, less prominent, and oblong in plan, while the building, larger and more elaborate, consists for the most part of a stone basement, with square doorways, but without windows, surmounted by a structure which appears to be directly copied from wood-work. On some of these façades we have also rude pillars and grotesque carvings, and there are often a number of chambers in the interior. A palace and temple are sometimes found attached together; and in a few cases, such as the Casa de las Monjas, at Uxmal, the buildings are arranged round a court-yard. See MEXICO. See *ILLUS., ARCHITECTURE*, vol. I.

TEOS (now *Sighajik*), an ancient Ionian city on the w. coast of Asia Minor; on a peninsula s.w. of Smyrna. Here was a celebrated temple of Dionysus, and a theater, of which remains still exist. It was a member of the Ionian confederacy and prosperous till the Persian conquest, when a large part of its inhabitants withdrew to Abdera in Thrace. Its principal production was wine. It was the birthplace of the lyric poet Anacreon.

TEPEE, the Indian name for a tent or a hut constructed of brush, leaves, and saplings. See WICK-I-UP, WIGWAM.

TEPIC, a t. of Mexico, in the state of Jalisco, on a height 400 m. n.w. of the city of Mexico. Tepic is the residence, during the rainy season, of most of the wealthy inhabitants of the port of San Blas, about 25 m. distant. Pop. estimated at from 14,000 to 25,000.

TERAMO (anc. *Interamna*), a t. of southern Italy, in the province of the same name, at the junction of the Tordina and Vezzola, 35 m. s. of Fermo. It is well built, with long and rather wide streets, has a cathedral, a public library, a foundling-hospital, and a botanic garden, carries on an active trade in corn, wine, and olives, and had a pop. of 95,000, commune, 21,100.

Ancient *Interamna* (of which the name Teramo is an Italianized form) was a city of Picenum in the territory of the Prætutii. In the middle ages it also bore the name of Abrutium or Aprutium (supposed to be a corruption of Prætutii), whence the modern name of the district, Abruzzo. Vestiges of the ancient city—a gateway, theater, baths, aqueducts, etc.—are traceable, and many statues, altars, and inscriptions have also been discovered. In the plain below Teramo took place, July 27, 1460, between the army of John, duke of Anjou, and the Milanese allies of Ferdinand I. of Aragon,

one of the most sanguinary battles ever fought in Italy. After the contest at Castelfidardo (1860), Teramo was the first Neapolitan city that opened its gates and gave joyful welcome to king Victor Emmanuel.—Pop. of province '81, 254,986; '95 (est.), 267,801.

TERAPHIM (Heb. plur.), a word of uncertain derivation (connected by some with *Serapis*), denoting certain images, idols, or household gods occurring in the Old Testament, which were consulted as oracles, and probably even worshiped to a certain extent. The gods which Rachel stole are called *teraphim*, and Saul was reproached by Samuel for stubbornness which is like *teraphim*; his daughter placed a *teraph* into David's bed to conceal his flight, etc. There is no proof that this veneration for *teraphim* was not held perfectly compatible with the worship of Jehovah, spite of some reformatory attempts to sweep them away. Many and curious have been the explanations given of the nature of the *teraphim* by different scholars in and out of the synagogue. A vague but generally prevailing notion is that of their having been a kind of astrological automata, which somehow or other could be made to move and to utter certain sounds. All that is certain, however, is only the fact that the real meaning and character of this strange idol had been forgotten already at a very early period.

TERATOLOGY (Gr. *terata*, wonders, or monsters) is a term used in physiology as synonymous with "The History of Montrosities or Anomalous Formations." See **MONSTROSITY**.

TERBIUM, a very rare metal, whose oxide, *terbia*, is found in association with the rare earth yttria, the oxide of yttrium (q.v.).

TERBURG or (TER BORCH), GERARD, a Dutch painter, of an old and respectable family of Zwoll, was b. about 1608, studied first under his father, who was also an artist of note, and afterward visited Germany, Italy, Spain, England, and France. On his return to his native country he settled at Deventer, of which town he became burgomaster, and died in 1681. The elegant ostentatious life of his time, with its superfine courtly manners and splendid costume, found in Terburgh an admirable painter. The central figure in many of his pictures is a young lady with fair hair and dressed in white satin. His most famous piece, however, is a picture containing portraits of the 69 plenipotentiaries who drew up the treaty of Westphalia. In Dr. Waagen's opinion, Terburgh is the real founder of the art of painting conversation-pieces, and at the same time the most eminent master in this style. "In delicacy of execution he is inferior to none, and in a certain tender fusing of the colors he excels all others; but none can be compared with him in the enchanting harmony and silvery tone, and the observance of the aerial perspective. His figures, which are well drawn, have an uncommon ease of refinement, and are frequently very graceful." Terburgh's works are to be found in various English collections; as also in the galleries of Dresden, Munich, Vienna, the Louvre, Amsterdam, and Berlin. See *illus.*, KAULBACH, ETC., vol. VIII.

TERCE (Lat. *tertia*, i.e., *hora*, the third hour), one of the "lesser hours" of the Roman breviary, so called from the time of the day for which it is fixed. See **CANONICAL HOURS**.

TERCE, in the law of Scotland, is the interest or estate which a widow has in the land of her deceased husband at common law. This amounts to a life rent of one-third of such estates. In estimating the estate of the husband all real burdens must be first deducted, and certain other things—as the mansion-house, if there is only one, superiorities and patronage, leases and feu-duties. The mode by which a widow completes her title to the *terce* is by a process called *kenning to the terce* (q.v.), the object of which is to separate her portion from the rest, which goes to the heir, so that each may possess independently his and her portion respectively. She is then in the position of an ordinary proprietor for life. Though *terce* is a legal right, yet this right of the widow may be modified by an ante-nuptial contract, under which she is otherwise provided for.—In England and Ireland a widow has a similar right, called *dower* (q.v.).

TERCEIRA, one of the Azores islands (q.v.), and the second in size of that group, forms one of the central cluster, and lies eastward from San Jorge. Area, 220 sq.m.; pop. '90, 46,528. Steep rocks of lava almost everywhere line the coast; the island is accessible only at few places, and these are defended against invasion by fortifications. The soil is fertile; the plateaux of the mountains afford excellent pastures, and cattle breeding is an important branch of industry; the principal articles of export are wine, timber, and orchil. Chief town of the island, Angra, the capital (pop. 18,000), in the fort of which reside the governor and the bishop of the Azores.

TEREBINTACEÆ. See **ANACARDIACEÆ**.

TEREBRANTIA, a section of the insect order *hymenoptera*, distinguished by the females having an ovipositor. To this section belong sawflies (*tenthredinidæ*), ichneumons, gall-insects, etc.

TEREBRATULA, a genus of deep-sea brachiopodous mollusca. The animal is attached to the shell by a pedicel, and the brachial disk is three-lobed, the center lobe being elongated and spirally convoluted. The shell is smooth, with a truncated perforated beak, the foramen being circular. The shelly loop is very short and simple.

The shell of this genus, and some of its allies, is covered with minute quincuncial perforations, sometimes visible to the naked eye, but usually requiring a lens of a low power to distinguish them. The generic title is now restricted to shells with a short internal loop. The species with long loops are grouped together under the name *Waldheimia*. Of the restricted genus, there is only a single living species (*terebratulula vitrea*); but the fossil species are more than a hundred in number, and are found in all periods of the earth's history, from the Devonian age upward. See *illus.*, *MOLLUSKS*, vol. X.; *MUSCHELKALK PERIOD*, vol. X.

TEREDO, a genus of lamellibranchiate mollusks of the family *pholadidae*; very much elongated, and worm-shaped; the mouth very delicate, open in front and at its lower part, for the passage of the short foot; the shell rather thick, equivalve, destitute of hinge, gaping at both ends. The species are rather numerous, and are generally known by the name of *SHIPWORM* or *PILEWORM*, because they perforate and live in timber. Their perforations are made in the direction of the grain of the timber, except when a knot is met with or the shell of another *teredo*, when they accommodate themselves to circumstances by bending. The cavity is lined with a calcareous incrustation. The aperture by which the *teredo* enters is small, and it grows within the cavity which it makes. Two small valves form the true bivalve shell; the calcareous tube incloses the worm-shaped body of the animal. Its growth is very rapid, and its ravages are often terrible. A piece of deal has been found riddled by shipworms after forty days' immersion. Ships, piles, and all submarine woodwork are destroyed by it. Copper-sheathing is employed to protect ships from the shipworm, or the timber is driven full of short, broad-headed nails, the rusting of which forms a coating which it does not penetrate. The dykes of Holland have been threatened with destruction by its ravages. The *COMMON SHIPWORM* (*teredo navalis*) is said to have been introduced into Europe from warmer climates. It is now, however, extremely abundant in European seas. In the East Indies, a very large species (*teredo gigantea*) is found, generally in shallow water among mangrove trees; it is sometimes more than five feet in length, and at the thickest part three inches in diameter. See *illus.*, *MOLLUSKS*, vol. X.

TEREK', one of the most considerable streams of the Caucasus, rises near the lofty mount Kasbec (about 17,000 ft. high), flows n.w. through the defiles of the mountains, crossing the district of the Kabarda, and reaches the border of the government of Stavropol, where it curves eastward, forming the s. boundary of that government, until, reaching Kisliar, it divides into numerous branches, which form a delta 70 miles broad; and falls into the Caspian sea. It is not navigable. Length, from 300 to 390 m.

TERENTIUS A'FER, **PUBLIUS** (or **TERENCE**), the comic poet, was born at Carthage, about 185 B.C. He was the slave of the Roman senator Publius Terentius Lucanus, who, out of regard to his handsome person and unusual talents, educated him highly, and finally manumitted him. On his manumission, he assumed, of course, his patron's *nomen*, Terentius. His first play was the *Andria*, written in his 27th year, but not acted till 166 B.C. Its success was immediate, and introduced its author to the most refined society of Rome, where his engaging address and accomplishments made him a particular favorite. His chief patrons were Lælius and the younger Scipio, after living with whom in great intimacy for some years in Rome, he went to Greece, where he translated 108 of Menander's comedies. He never returned; and the accounts of how he came by his death are conflicting. He is supposed to have died in his 36th or 37th year, leaving one daughter. Six comedies are extant under the name of Terentius, which are, perhaps, all he produced—viz., *Andria*, *Hecyra*, *Heauton-timoroumenos*, *Eunuchus*, *Phormio*, and *Adelphi*. In conjunction with Plautus, Terentius, on the revival of letters, was studied as a model by the most accomplished play-writers. His language is pure almost to being immaculate, and though inferior to Plautus in comic power, he is more than his match in consistency of plot and character, in tenderness, in wit, and in metrical skill. His plays have an educational value, as dividing, with the works of Cicero and Cæsar, the honor of being written in the purest Latin. They have been translated into most of the European languages. The best editions of his works are those of Bentley (Cambridge, 1726), and of Parry (1857).

TERESA, SAINT, one of the most remarkable of the female saints of the modern Roman calendar, and the most admired of the modern mystic writers of that communion, born at Avila, in Old Castile, March 28, 1515, was the daughter of Alfonso, of the noble house of Sanchez de Ceyeda. Even as a child, Teresa was remarkable for piety of a most enthusiastic kind; and when she was but seven years old, she and her little brother, Rodrigo, fled from her father's house, with the design of offering themselves for the crown of martyrdom among the Moors, but were overtaken and restored to their parents. Her mother died while she was still young, and she was educated in a convent at Avila, from which, however, she was compelled by illness to return home when she was in her 16th year. During her illness, she resolved, notwithstanding the very earnest opposition of her father, to become a nun, and having in her 18th year entered a convent of the Carmelite order in her native city, she made her solemn vow on the 3d of November, 1534. In this convent she continued to reside for nearly thirty years, but it was not until about the year 1539 that her constitution became strong enough to permit her to follow, even in an imperfect way, the observances of conventual life. Her own

account of her mental and spiritual condition during this period, which extended to the year 1555, is extremely interesting, and, like the confession of St. Augustine, and other saints, has furnished endless materials to the spiritualists of more recent times. The change of heart and of purpose came in 1555-1556, and was as complete and decisive as her former condition had been purposeless or fluctuating. After a time her religious exercises reached a most extraordinary degree of asceticism. Her prayers were almost continual, and she was reported to be favored with visions, ecstasies, and other supernatural visitations, of which many curious details are related by her biographers, and in her own letters and papers. The fame of her sanctity spread not only throughout Spain, but into almost every part of the church. By some, the reality of the reported supernatural favors which were ascribed to her were called into question; and there were even some who threatened to invoke the rigorous investigation of the holy office; but the popular voice was freely accorded to her, and the authority of St. Francis Borgia, St. Peter of Alcantara, and other high names eventually disarmed the opposition. The most notable and permanent fruit of the enthusiastic spirituality of Teresa is the reform of the Carmelite order, of which she became the instrument. She commenced this work in concert with a few zealous members of her own sisterhood in the convent at Avila, where she had resided from the date of her profession; but after a time, she obtained permission from the holy see, under the direction of Peter of Alcantara, to remove with her little community to St. Joseph's, a small and very humble convent in the same city, where she established in its full rigor the ancient Carmelite rule, as approved by Innocent IV. in 1247, with some additional observances introduced by Teresa herself. This new convent was established in 1562, and in the end of that year, or the beginning of 1563, Teresa took up her abode therein; and in 1565 she obtained from Pope Pius IV., a formal approval for the rule as modified by her. For two years Teresa lived in great privacy and quiet in her convent of St. Joseph; but in 1567, the general of the Carmelite order, F. Rubeo, was so struck, during his visitation of the convents at Avila, with the condition of that over which Teresa presided, that he urged upon her the duty of extending throughout the order the reforms thus successfully initiated. Teresa entered upon the work with great energy, and although she met with much opposition, nevertheless succeeded in carrying out her reforms. In 1579, the Carmelites of the stricter observance established by Teresa were released from the jurisdiction of the old superiors, and united into a distinct association, with a separate head and a distinct organization, which was approved in 1580 by Pope Gregory XIII. Under this new constitution, the association flourished and extended; and within the lifetime of Teresa, no fewer than 17 convents of women and 16 of men accepted the reforms which she had originated. Teresa died at Alba, October 4, 1582, in her 68th year. She was canonized by Gregory XV. in 1621, her feast being fixed on the 15th of October. She left a number of works, which have at all times maintained a high reputation among the spiritualists of her own church, and whose merits, in many respects, are acknowledged by non-Catholic writers. They consist of ascetical and mystical treatises, instructions in the conventual life, meditations, etc., besides a large number of letters, which possess remarkable literary merit, quite independent of their doctrinal character. Her works in the original Spanish fill two folio volumes, and they have been in the whole or in part translated into almost every European language. Her life occupies nearly an entire volume of the new continuation of the *Acta Sanctorum*; and several more popular biographies have been written in Spanish, French, Italian, German—the best-known English one being that by the Rev. Canon Dalton. See *Leben der heil. Theresia* von Dr. Fr. Pösl (Regensburg, 1847).

TERHUNE, MARY VIRGINIA (HAWES), b. N. Y., 1835; married, 1856, the Rev. Dr. Edward P. Terhune, pastor of Bedford ave. Reformed church, Brooklyn, N. Y., 1884-91; contributed at the age of sixteen to *Godey's Lady's Book* a sketch entitled *Marrying from Prudential Motives*, which was copied into an English paper, thence transferred to a French journal, retranslated into English, and published in England and America as an English story. Her publications are: *Alone*; *The Hidden Path*; *Moss Side*; *Husbands and Homes*; *Miriam*; *Nemesis*; *Sunnybank*; *Husks*; *The Christmas Holly*; *Ruby's Husband*; *Phemie's Temptation*; *Helen Gardner*; *The Empty Heart*; *Common Sense in the Household*, a book of domestic recipes; *Loiterings in Pleasant Paths*, etc. She is best known by her nom-de-plume of Marion Harland.

TERLIZZI, a flourishing, well-built town of Italy, in the province of Bari, 17 m. s.e. of Barletta, and 8 m. from the Adriatic. It contains a cathedral, a parish church, and three convents. Pop. '81, 20,442.

TERM, in legal phrase, has several meanings, but that best known is when it denotes certain days of the year for calculating rent between landlord and tenant, and which have been adopted by immemorial usage, owing to the convenience of thus terminating the contract between the parties. In England and Ireland the year is for this purpose divided into four quarters or terms. These are—Lady-day, Mar. 25; Midsummer-day, June 24; Michaelmas-day, Sept. 25; and Christmas-day, Dec. 25. In Scotland, the terms as between landlord and tenant are divided into legal and conventional terms. There are two terms recognized by common law, viz., Whitsunday, May 15; and Martinmas, Nov. 11; while other two conventional terms subdivide these, viz.,

Candlemas, Feb. 2; and Lammas, Aug. 1.—There is also a subdivision of the year into law-terms (q.v.), adopted and sanctioned by statute for the purpose of the sittings of the law-courts. These are Hilary, Easter, Trinity, and Michaelmas terms.—There is a third and technical meaning of the word "term," when it means an estate for years in land.

TERMINI (anc. *Thermæ Himærenses*), a seaport town on the n. coast of Sicily, 21 m. e.s.e. of Palermo, at the mouth of the river San Leonardo. It is built partly on a plateau (the summit of which is crowned by a castle—now a prison—of mediæval construction), and partly on the slope and in the hollow beneath. Termini, with its noble background of towering hills, and its magnificent view of the Mediterranean, well deserves the title of *La Splendidissima*, bestowed on it by the emperor Frederick II. Many of the inhabitants are engaged in fishing for tunny and anchovies. Pop. '81, 22,733.

The ancient *Thermæ* (of which Termini is an Italian corruption) was founded 408 B.C., after the destruction of the Greek city of Himæra, and whence its name Himærenses. Whether it owed its origin to the Carthaginians themselves, or to the surviving citizens of Himæra, is doubtful; but it soon passed under the authority of the former, who here defeated the Romans with heavy loss (260 B.C.) during the first Punic war. After Sicily became a Roman province, *Thermæ* was treated with peculiar consideration by its new masters, and became a flourishing place. Relics of the ancient city, as the baths (which are still used), fragments of a theater and aqueduct, are still visible; and numerous inscriptions, statues, etc., are preserved in public and private collections.—See B. Romano's *Antichità Termitane* (Palermo, 1838); Battaglia, *Storia di Termini* (Palermo, 1896 ff.).

TERMINUS, a Roman divinity, supposed to preside over public and private boundaries. Originally he appears to have been the same as Jupiter himself, but gradually he was recognized as a separate and distinct god. Hardly any religious conception is more thoroughly characteristic of the Romans, that land-loving, law-reverencing people, than the conception of Terminus, whose worship was practiced down to a late period.

TERMITE, or WHITE ANT, *Termites*, a genus of insects of the order *neuroptera* (q.v.), and of the family *termitidæ* or *termitinæ*. They live in great communities, chiefly in tropical countries, and are almost omnivorous, in the larva, and pupa, as well as in the perfect state. In their communities there are five classes—males, females, workers, neuters, and soldiers. The workers, neuters, and soldiers seem all to be imperfectly developed females. The males and perfect females have four wings, which are long and nearly equal, and which are often suddenly cast off before the termination of their life; but the greater part of the community consists of workers, which are wingless. The "soldiers" are larger than the neuters, and have very large mandibles, which they are always ready to use upon any assault. The antennæ of the genus *termes* are long and thread-shaped, with about 20 joints; the eyes are small and prominent, and there are three *ocelli*; the abdomen has a pair of minute caudal appendages. Most of the white ants make their nests on the ground, but some of them among branches of trees, decayed or dry wood forming a principal article of their food. The species which make their nests on the ground make them conical, or turret-shaped, often 12 ft. and sometimes even 30 ft. high, in groups, like a little village. The soil where the white ants have labored is particularly good, and the south Africans take advantage of its excellent quality. The nest is divided internally into numerous chambers and galleries; there are generally two or three roofs within the dome-shaped interior, and the thick walls are perforated by passages leading to the nurseries and magazines of food. If a breach is made in the building, the soldiers appear, ready for defense. White ants are very useful in consuming every kind of decaying animal or vegetable matter. They even eat grass, and the snapping of multitudinous mandibles has been likened to the sound of a gentle wind among trees. They sometimes attack the wood-work of houses, and soon reduce the thickest timbers to a mere shell. Extraordinary and incredible stories are told of their attacking and devouring large animals, but it seems probable that they do so only when the animals are helpless from age or sickness. They come in vast hosts to any place where food is to be found, and are not easily driven off; multitudes pressing on, although previous multitudes have been destroyed. They gather great stores of corn into their nests, of which the natives of Africa often avail themselves. They are themselves also used as food in Africa, and are said to be delicate and pleasant. The abdomen of the pregnant female termite becomes dilated to an extraordinary degree, so as to exceed the rest of her body 1500 or 2,000 times, and she is then about 1000 times heavier than the male insect. Her fecundity is prodigious; she is supposed to lay more than 31,000,000 of eggs in a year.

The termites which live in trees construct nests of great size, like sugar-casks, of particles of gnawed wood, cemented by a kind of gluten, and so strongly attached to the branches as not to be shaken down even by violent storms. These species sometimes take up their abode in the roofs of houses, where they are very destructive to the wood-work.

T. mordax and *T. atrox* are among the African ground-building species. *T. lucifugus* is found in the s. of Europe, and has proved very destructive in the navy-yard of Rochefort, and elsewhere in the s. of France. Sulphurous gases and chlorine are forced into its galleries, without effecting its extirpation. *T. flavicollis* is very injurious to olive trees in Spain. *T. frontalis* extends as far n. in the United States as Massachu-

setts, and does mischief in vineries, not only attacking dead wood, but the roots of living vines. No true species of *termes* is found in Britain, but some of the *termitidæ* are British insects. One of them is *psocus pulsatorius*, one of the insects which emit a sound like the ticking of a watch in houses. The species of the genus *psocus* are very small, active insects, living beneath the bark of trees, in wood, straw, among books, etc.

In books of travels, the termites are often called ants, their habits being similar, although they belong to a different order of insects. See *illus.*, BEETLES, ETC., vol. II., *figs.* 1-8.

TERN (*Sterna*), a genus of birds of the gull family (*laridæ*), by some made the type of a distinct family (*sternidæ*); having the bill as long as the head, or longer, nearly straight, compressed, slender, tapering; the wings long and pointed; the tail long and forked. The plumage is very full. From their forked tail, manner of flight, and small size, the terns are often called sea-swallows. They are incessantly on the wing, skimming the surface of the water, and catching small fishes and other small animals from it. The species are numerous, and are found in almost all parts of the world. Some of them are of very wide geographic distribution. Many are birds of passage. Thus, all which occur on the British coasts, and in other northern parts of the world, are mere summer visitants. The COMMON TERN (*S. hirundo*) is abundant on the more southern shores of Britain, but rarer in the north. It is found also on the coasts of Europe, Asia, and Africa, from the Arctic circle to the furthest s.; but there is some doubt if its range extends to America, where a very similar species, WILSON'S T. (*S. Wilsoni*), was long mistaken for it.

TERNANT, JEAN DE, Chevalier, 1750-1816, b. France; was with the French army in America during the revolutionary war. Baron Steuben made him one of his inspectors in 1778. He was afterward lieut. col. and inspector of troops in the south, was captured at the surrender of Charleston in 1780. After his exchange he returned to his former position in the south. He was a col. in the French army during the French revolution, and minister to the United States, 1790-93.

TERNATE. See **MOLUCCAS**.

TERNAUX, GUILLAUME LOUIS, Baron, 1763-1833, b. Sedan, France. When but a boy he became manager of his father's woolen mill, and by his business sagacity rescued its finances from ruin. He was a deputy to the assembly, 1818-23 and 1827-30. The revolution of 1830 was brought about by the position taken by Ternaux and his party, and by it he lost a large fortune. He introduced improvements in manufactures and wrote several treatises on financial and industrial subjects. His nephew, HENRI TERNAUX-COMPANS, 1807-64, was noted as a collector of old books, his library of works bearing on the discovery and conquest of America being the finest in existence. He published a *Bibliothèque Américaine*, 1493-1700 (1836).

TERNAY, CHARLES LOUIS D'ARSAE DE, 1722-80, b. France; entered the French navy in 1738. In 1762 in command of a squadron he attacked Newfoundland, and captured St. John's, and several British vessels. He was governor of the island of Bourbon, 1772-79. The next year he commanded the French fleet bringing over to America count Rochambeau and his forces. He died at Newport soon after his arrival.

TERNI (anc. *Interamna*) a t. of central Italy, on the right bank of the Nera (anc. *Nar*), a little below its confluence with the Velino, 49 m. n.n.e. of Rome. It is encircled by a wall, with towers and five gates, is well-built, gives name to an archbishopric, and possesses a cathedral, several fine palaces and churches, a hospital, theater, and various monuments of antiquity, as the ruins of an amphitheater, temples, and baths—none of which, however, are of much importance. Terni manufactures silk and woolen fabrics. Pop. (communal), '81, 15,853. About 2 m. from the town is the famous cataract of Velino, 500 ft. high, celebrated by Byron in his *Childe Harold*.

Ancient *Interamna*, according to classic tradition, was founded only 80 years after Rome, but we have no knowledge of its history until it ceased to be an Umbrian, and became a Roman city. About the time of Marius and Sulla, it was (according to Florus) one of the *florentissima Italia municipia*, but at no period did it occupy a very prominent position. Its chief claim to notice arises from its being regarded (by some) as the birthplace of the historian Tacitus, and of his descendant, the emperor of the same name.

TERNSTROMIA CÆ, a natural order of exogenous plants, allied to *guttifere*, and consisting of trees and shrubs, natives of warm and temperate countries. About 150 species are known. They are most abundant in South America; a few are found in North America; some in India, China, and other parts of the east; only one African species is known; and Europe produces none. The leaves are alternate, leathery, in many species evergreen, generally undivided, sometimes dotted. The flowers are on axillary or terminal stalks, generally white, sometimes pink or red; with 5 to 7 concave, leathery, deciduous sepals, and 5 to 9 petals, which are often combined at the base; many hypogynous stamens, which are either free or variously combined: 2 to 7 filiform styles, more or less combined: the fruit a 2 to 7-celled capsule, either opening by valves, or leathery and indehiscent, the seeds large, few, and attached to the axis, the cotyledons very large, and often containing much oil. This order is very important as containing the tea-

shrubs. It is also interesting because of the great beauty both of the foliage and flowers of many of the species, of which the genus *camellia* affords the best-known examples. See TEA, CAMELLIA, and GORDONIA.

TERPAN DER, a Greek musician who flourished in the beginning of the 7th c. B.C. He was born at Antissa in the island of Lesbos; went to Sparta, and in 676 was crowned victor in the first musical contest at the feast of Apollo Carneius. He established there the first musical school in Greece. He enlarged the compass of the lyre to an octave, and was the first who regularly set poetry to music.

TERSICH ORÉ (Gr. delighting in the dance), one of the nine muses (q.v.), presided over choral song and dancing.

TERRACINA (anc. *Tarracina*), a t. of central Italy, in what was formerly the Papal States, is situated on the coast at the s.e. extremity of the Pontine Marshes, near the mouths of the Ufente and Amaseno. It is the seat of a bishop, possesses a cathedral (built on the ruins of a heathen temple), a square with a handsome fountain, and on the summit of a precipice overlooking the town, the ruins of an imposing *Temple of Venus*, supposed, until the excavations of 1894, to have been a palace of Theodoric, king of the Goths. The harbor, a naval station of the Romans, is now filled up. Pop. '81 (communal), 8572.

Tarracina was originally a Volscian town, and was called by the Volscians *Anxur*, a name which is often applied to it by the Latin poets. It fell into the hands of the Romans, 400 B.C., became the seat of a Roman colony, 329 B.C., and as long as there public and empire lasted was a flourishing and important city. So closely do the mountains here approach the sea that there was scarcely room for the celebrated "Applan way;" hence the importance of Tarracina as a military position. Numerous ruins of the ancient town are extant.

TERRA or **TELLUS**, in classical mythology, one of the oldest of divinities, the earth-goddess, wife of Uranus, mother of Oceanus, the Cyclops, the Titans, the giants, Themis, Mnemosyne, etc. Her festival was on April 15, and sacrifices were offered to her in spring and autumn. She corresponds to the Greek Ge, called by Hesiod the first-born of Chaos.

TERRA COT'TA, an Italian term signifying *baked clay*. It is applied chiefly, if not altogether, to manufactures of brick-earth used for ornamental purposes, especially those used architecturally. Formerly it was not uncommon in Britain, particularly about the beginning of the 18th c.; but after the reign of Queen Anne it was discontinued, and was scarcely ever used until about the year 1860. A complete revival has now taken place, and this material has been applied with admirable effect in some of the buildings lately erected, especially the South Kensington museum and many public buildings in the United States.

TERRA DEL FUEGO, or **TIERRA DEL FUEGO** (Land of Fire), an archipelago situated at the extreme s. of South America, and separated from the main land by Magellan's Straits, bet. 52° 28'-55° 59' s. lat. and 63° 42'-74° 48' long. w. from Greenwich, with a total area of about 28,400 sq. miles. It consists of one principal island, King Charles's South Land, containing 21,300 sq. miles, or about three-fourths of the whole area, the seven islands Desolation, Clarence, Dawson, Hoste, Navarin, Wollaston and State island, and numerous islets, the most southern of which ends in Cape Horn. All the islands are very irregular and cut by deep fiords, affording magnificent scenery. The eastern coasts are as a rule level, while the western coasts are rocky and mountainous, forming the southern extremity of the Cordillera system. Some of the peaks are over 6000 feet high and partly covered with perpetual snow, but there are no active volcanoes. The eastern part of King Charles's South Land contains some good pasture land, while gold has been found in paying quantities. The climate is raw and cold, and violent rain and snow storms occur, especially from June to October. The natives, whose number is estimated at about 8000, belong to two distinct races, those in the northeast of the main island, the *Ona* tribe, being tall, well-built men, closely resembling in speech and habits the tribes north of Magellan's strait, while the Fuegians, properly so called, and the *Jahgan* and *Alacaluf* tribes on the islands further south are small of stature, with coarse features and long, straight hair, and occupy a low rank in the scale of humanity. Their food consists mainly of fish and shellfish, seals, berries, etc. Their language possesses no expressions for numerals above three, yet it has a highly developed grammatical structure, the verb possessing three subjunctive forms, an interrogative form, and a form expressing impossibility, while substantives are declined in four numbers, singular, dual, trial, and plural. The English South-American mission has had a station in Uschuia for some years, with over three hundred native Christians, who occupy themselves with farming and cattle-raising. By a treaty concluded July 23, 1881, Chile and the Argentine Republic divided Terra del Fuego between them, the Argentine Republic receiving that portion of the main island east of 68° 34' w. long., together with State island, thereby getting about 8000 sq. miles, while Chile's share was over 20,000 sq. miles. The Chilean division has been attached to the territory of Magelanes; that of the Argentine Republic forms the government Terra del Fuego, with three departments. The seat of government, formerly at Uschuia, has been transferred to Buen Suceso.

The island of Terra del Fuego was discovered by Fernão de Magalhães, in 1520, but, although often visited, was never systematically explored until after the political division of 1887, since which time they have been explored by Bossi, Bove, Lista, Popper, Rousson and Willem. From Sept. 5, 1882, to Sept. 1, 1883, the island Hoste was the seat of a French polar station. See Fossarieu, *Ethnographie de l'Amérique Antarctique* (Paris, 1884); Bove, *Patagonia, Terra del Fuego, etc.* (Genoa, 1883), Serrano, *Derrotero de Estrecho de Magallanes, Tierra del Fuego, etc.* (Santiago, 1891).

TERRA DI LAVORO (*Campania Felix*), now CASERTA, a maritime province of s. Italy, bounded on the n.w. by what was formerly the Papal states. Area, 2086 sq. m.; pop. '90, (est.) 732,810. This is the famous *Campania Felix* of the ancients. Pliny extols its beauty and its fine situation. Florus calls it the finest country in the world. In ancient times it was inhabited by the Ausonii, the Osci, and later by the Campani. The finest part of Campania has been separated from it, and is that fertile tract of country which surrounds the gulf of Naples; another part has been added to the province of Molise.

TERRA DI SIENNA. See BURN'T SIENNA.

TERRÆ FILIUS. A Latin phrase from which comes our English expression, "son of the soil." Cicero and Persius use the expression. In one of his letters to Atticus the former says: "I cannot venture to trust a letter on matters of such importance to this son of the soil, when goodness knows who he may be." Tertullian explains its significance: "The people call those persons *sons of the soil* whose pedigree is doubtful," as does also Minucius Felix: "We call the ignoble and unlearned, 'sons of the soil.'" The transition from this last to the English meaning is an easy one.

TERRA FIRMA, a term frequently employed to denote continental land as distinguished from islands. But it was at one time more specially applied—1st, to all the mainland of Italy which acknowledged the supremacy of Venice—viz., to the duchy of Venice, Venetian Lombardy, the march of Treviso, the duchy of Friula and Istria; 2d, to that extensive tract of South America bounded by the Pacific ocean, Peru, the silvas of the Amazon, the Atlantic ocean, and the isthmus of Panama, which mostly belonged to the Spaniards during the last century. In a still more restricted sense, the term was applied by the Spaniards to the isthmus of Panama itself. Colloquially, the phrase *terra firma* is applied (but erroneously) to land as distinguished from water.

TERRANOVA, a seaport town on the s. coast of Sicily, province of Caltanissetta, on the right bank of the Maroglio, 18 m. e. from Licata. Pop. '81, 17,173. The town carries on a considerable trade. Terranova is believed to occupy the site of the ancient Gela (q. v.). The town now standing was built by Frederick II. in the 12th century. In its neighborhood is the village of Mazarino, from which the famous cardinal took his name.

TERRAPIN, the popular name of many species of fresh-water tortoises, of the family *emydæ* (see EMYS), natives of tropical and the warmer temperate countries. The neck can be wholly retracted within the shell; the head is flat, and the jaws prolonged into a beak. They feed partly on vegetable food, but also devour fish, reptiles, and other aquatic animals. They swim very well, and even on land move with much greater swiftness than land-tortoises. Their flesh is generally much esteemed. Several species are natives of North America.

TERREBONNE, a parish in s.e. Louisiana; bounded on the s. by the gulf of Mexico, on the w. by Atchafalaya bayou, drained by Black, Caillou, Chene, and Terre Bonne bayous; traversed by the Southern Pacific railroad; about 1800 sq. m.; pop. '90, 20,167. The principal productions are corn, molasses, and sugar. Parish seat, Houma.

TERREBONNE, a co. in s.w. Quebec, lying n.w. of the isle of Jesus, having the St. Lawrence river for its s. boundary; 545 sq. m.; pop. '91, 23,128. It is drained by the North river, which empties into the Ottawa. It has saw, grist, and woolen mills. Co. seat, St. Jerome.

TERRE HAUTE, city and co. seat of Vigo co., Ind., on the Wabash river, and the Chicago and Eastern Illinois, the Cleveland, Cincinnati, Chicago, and St. Louis, the Evansville and Terre Haute, the Vandalia line, and several other railroads; 73 miles w. of Indianapolis. It is built on prairie land on a bluff 60 feet above high water, is underlaid with block and bituminous coal, is within a few miles of the great block coal mines of Clay co., and is surrounded by a fertile farming region. The city is handsomely and regularly laid out; has several public parks and squares, of which Collett (30 acres) and Deeming (80 acres) are the most attractive; and has electric lights, electric street railroads, waterworks on the Holly system, well-paved streets and good sewerage. Terre Haute contains the state normal school, the Rose polytechnic institute, Coates female college, Rose orphan home, St. Ann's orphan asylum, Union home for invalids, old ladies' home, St. Anthony's hospital (R. C.), St. Mary's institute (R. C.), and the Rose dispensary. Other noteworthy buildings and institutions are the U. S. government building, co. court-house, city hall, union railroad station, high school, and

public, law, and school libraries. There are over 30 churches, national, state, savings, and private banks, and several daily, weekly, and monthly periodicals. The U. S. census of 1890 reported for Terre Haute 367 manufacturing establishments, employing \$4,965,184 capital and 5205 persons, paying \$2,154,001 for wages and \$6,785,616 for materials, and having a combined output valued at \$13,720,529. The principal manufactures are rolling mills, blast furnaces, flour and hominy mills, distilleries, breweries, nail works, railroad car shops, tool factories, paving brick, and other clay works. There are also large grain elevators. The town was founded in 1816, and was chartered as a city in 1852. Pop. '90, 30,217.

TERRELL, a co. in s.w. Georgia, drained by the Flint river and its creeks; traversed by the Central of Georgia railroad; about 320 sq. m.; pop. '40, 14,503. Co. seat, Dawson.

TERRE-PLEIN, in fortification, is the flat surface of the rampart, on the front portion of which the parapet and banquette are formed, and of which the rear slopes down to the general level of the inclosure.

TERRESTRIAL MAGNETISM. In the article **MAGNETISM**, it is shown that the earth itself is to be considered as a great magnet; and in the present article it is proposed to exhibit the chief results of observation on the earth's magnetism as seen in its action on artificial magnets. That action is simply *directive*; that is, it determines the way in which the magnet shall point, but has no tendency to translate or move it bodily. Terrestrial magnetism acts differently at different places; what are called the *magnetic elements* of a place are the direction of the needle in regard to the points of the horizon (*variation or declination*), its direction in regard to the vertical (*inclination or dip*), and the force that keeps it in these positions (*intensity*). For the first two elements, see DECLIN-

FIG. 1.

ATION-NEEDLE and DIPPING-NEEDLE. The element of intensity is more difficult to determine. The relative horizontal intensity is measured by the number of oscillations that a needle, of unit size and strength, when disturbed makes in a given time, the intensities of two places being as the squares of the oscillations. The total intensity is got by dividing the horizontal intensity by the cosine of the angle of dip. Gauss has succeeded in reducing this measurement from a relative to an absolute standard.

Magnetic Charts.—The magnetic elements have been ascertained with great care at different portions of the earth's surface. The knowledge thus obtained has been embodied in magnetic charts, in which the points at which the declination is the same are joined by lines, and similarly those where the dip and intensity are alike. The lines of equal declination are called the isogonic lines; those of equal dip, isoclinic; and those of equal intensity, isodynamic lines. As the magnetism of the earth is subject to a slow secular variation, such charts are only true for the time of observation. The chart, fig. 1, was drawn up by col. Sabine for the year 1840, and gives an approximate view of the lines of equal declination for that year. The change since 1840 has been small, so that an isogonic chart for the present time would differ but slightly from it. The chart sufficiently explains itself. Attention may, however, be given to one or two points. The declination is marked on each line. Thus, the line passing through England, for instance, is marked 25°, and that passing n.w. of the British islands, 30°. At places under those lines the needle points to a n. 25° and 30° w. of the true north. On the space intervening

between these lines, including Scotland and Ireland, a correction, varying from 0° to 5° , must be made according as the station lies more toward the one line than the other. The westerly line of no declination passing northward cuts off the eastern corner of South America, proceeds to North America, which it enters at North Carolina, traverses the continent by lakes Erie and Huron and the w. of Hudson's bay, and ends in the n. of the continent at Boothia. The easterly line of no declination passing southward enters Europe in the n. of Russia, crosses the White sea to the e. of Russia, of the Caspian sea, of Persia, and the Arabian sea; then turns eastward, and cutting off the w. of Australia, passes southward. The space included between those two lines, and which in the chart is left untinted, constitutes, so to speak, the hemisphere of westerly declination. It includes the e. of the two Americas, the Atlantic ocean, the whole of Europe and Africa, and the w. of Asia and Australia. The rest of the earth, which in the chart is tinted, has an easterly declination. There is an elliptic space in Eastern Asia which is left white, having a westerly variation, and forms an exceptional region in the eastern magnetic hemisphere.

It will be seen that the lines converge in the n. of North America, and in the s. of Australia. So far as experience goes, and so far as the most matter-of-fact theory (Gauss's) teaches, the convergence in both cases is to a point. The point in North America is the *north magnetic pole*, and that s. of Australia is the *south magnetic pole*. At these points, then, all isogonic lines converge, and a compass-needle lies indifferently in any position.

These isogonic lines, as seen from the chart, form a somewhat complicated system. This arises from the fact that we refer the indications of the needle to the geographical poles, which are, so far as we know, arbitrary or extraneous as regards terrestrial magnetism. Duperrey, by drawing what he calls *magnetic meridians and parallels*, draws a system of lines which have much the same conformation with regard to the magnetic poles that the meridians and parallels of latitude have to the geographical poles. A magnetic meridian, according to Duperrey, is the line that would be described by a person setting out, say from the south magnetic pole, and traveling always in the direction of the magnetic n. till he reached the n. magnetic pole. The magnetic parallels are lines drawn at right angles to the magnetic meridians.

In an isoclinic chart by the same author and for the same epoch in the upper part of the chart, which is left white, the n. end of the needle dips; and in the lower part, which is tinted, the s. end of the needle dips. The amount of dip is marked on lines. Thus, the line passing through the center of England is marked 70° . A dipping-needle, at any place cut by the line, is inclined 70° to the horizon. The line 75° passes to the n. of the British isles. In Ireland and Scotland, therefore, the dipping-needle has an inclination greater than 70° , and less than 75° . The line marked 0° is the line of no dip; at any station on it the dipping-needle is horizontal. This line is called the *magnetic equator*. It is not coincident with the geographical equator; it is not even a great circle of the earth, but is an irregular curve cutting the equator in two points, one near the w. coast of Africa, and the other in the middle of the Pacific ocean. The points on the earth's surface where the dipping-needle stands vertical, and where, in consequence, as before mentioned, the compass-needle lies in any direction, are called the magnetic poles. The n. magnetic pole was found in Boothia Felix by capt. Ross at $70^{\circ} 5' \text{ n. lat. and } 263^{\circ} 14' \text{ e. long.}$ According to Gauss's calculation, it should have been at the time (1831) some 3° n. of this point. From observations made at Hobart Town, the nearest station to it, the s. magnetic pole should lie $66^{\circ} \text{ s. lat. and } 146^{\circ} \text{ e. long.}$ These points are not diametrically opposite each other, as the geographical poles. If the lines of equal dip were drawn on a globe, they would form round the magnetic poles a system of irregular circles, somewhat resembling that of the parallels of latitude round the poles of the earth.

We do not add an isodynamic chart, as it would take up too much space. Col. Sabine's dynamical chart, along with the isogonic and isoclinic charts, will be found fully engraved and explained in Johnston's *Physical Atlas* (new edition). From this chart we learn that the magnetic intensity is least in the vicinity of the magnetic equator, and increases as we approach the magnetic poles. The lines of equal intensity, though running much in the same direction as the lines of equal dip, are neither coincident nor parallel with them. The line of least intensity, itself not an isodynamic line, runs nearly parallel to the magnetic equator, but lies, except in the western half of the Pacific, a few degrees to the s. of it. We thus learn that the changes in direction and intensity do not march together. We should fancy that at that point or points on the earth's surface where the dipping-needle stood erect we should be nearest to the center of free magnetic energy, and that there the force would be greatest; but this is not the case. The point in North America where the intensity is greatest is situated to the w. of Hudson's bay, some 18° s. of the n. magnetic pole. But this is not the only point of maximum force in the n. magnetic hemisphere. There is another, which was found by Hansteen in 1828, in Northern Siberia, about the longitude 120° . This maximum point is weaker than the American, in the proportion of 100 to 107 (Sabine). According to Gauss, there can only be one maximum point in the southern hemisphere which is stronger than either of the other two. It lies n.e. of the s. magnetic pole, and its intensity is 137 (Gauss) compared with 107, that of the principal northern center. At none of those

points does the dipping-needle stand erect. This want of coincidence of the points of vertical dip and of maximum intensity has led to some confusion in the use of the term magnetic pole; some writers meaning by it a point of vertical dip, and others a point of maximum intensity. In adopting the former definition we are only adhering to the popular meaning of the word, and to the opinion of Gauss, perhaps the greatest authority on the subject. Some of the best English authorities, however, attach to it the latter meaning.

Although the total intensity increases as we go northward or southward from the line of least intensity, the horizontal intensity diminishes. This arises from the fact that the greater the dip the less the horizontal intensity. Hence the compass-needle, which is affected alone by the horizontal intensity, oscillates more sluggishly as we leave the line of least intensity. A dipping-needle, for instance, oscillates faster at London than at Calcutta, because the total intensity which affects it is greater at London than at Calcutta; but with a compass-needle it is the reverse, from the horizontal intensity being greater at the latter than at the former station.

Variations of the needle.—The magnetic elements do not remain constant in the same place, but are subject to continual though small variations. These are regular and irregular. Under regular variations are included *secular*, *annual*, and *diurnal* variations. The secular variations take centuries for their completion. The following list of the declination and dip at London in different years will give an idea of the secular variations for these elements:

| Year. | Declination. | Year. | Inclination. |
|--------------|-----------------------|-----------|--------------|
| 1576..... | 11° 15' easterly. | 1720..... | 74° 43'. |
| 1657–62..... | 0° 0' no declination. | 1780..... | 72° 8'. |
| 1760..... | 19° 30' westerly. | 1800..... | 70° 35'. |
| 1815..... | 24° 27' 18" westerly. | 1830..... | 69° 38'. |
| | MAXIMUM. | 1850..... | 68° 48'. |
| 1850..... | 22° 29' 30" westerly. | 1865..... | 68° 9'. |
| 1865..... | 21° 6' “ | 1875..... | 67° 47'. |
| 1875..... | 19° 33' “ | 1882..... | 67° 31'. |

At present the annual decrease of declination at Kew is 8'. At this rate it would take rather more than 84 years for the compass-needle to shift through a whole point. From the observations of the dip we find that it has been gradually decreasing for the last 150 years. The annual decrease of dip is at present about 2.6'. The time during which observations have been taken of the declination and dip is far from comprehending a cycle of change in either, and it is a mere matter of speculation how long that may take. The magnetic history of London does not apply to other places, each place, so far as has been ascertained, having a magnetic history of its own. Thus, in Paris, the time of no declination was 1669; and of maximum declination, 1814; the latter amounting to 22° 34' west. Every place, according to Barlow, appears to have its own magnetic pole and equator. Magnetic intensity has been observed for so short a time that little as yet is known of its secular variation. At present the horizontal intensity is increasing in Europe, but that may arise partly from decrease of dip.

The magnetic elements are also subject to changes, which have a yearly and a daily period. In describing these shortly, we shall limit ourselves to the changes affecting declination, as these are of most general interest. The following are the chief particulars of the *annual variation* of declination given by Cassini: From April to July, or from the vernal equinox to the summer solstice, the western declination decreases. From the summer solstice to the vernal equinox, that is, during the other nine months of the year, the declination increases, the needle turning to the west. Its position in May and in October is nearly the same; so that in the winter months, from October to April, the westerly motion is slow. The range of the annual variation at Kew is 58'.85.

The mean *diurnal variation* for Kew is shown in fig. 2. The irregular line indicates the course of the n. end of the needle. A rise of this line indicates a change of the n. end to the e.; a fall, a change to the west. The interval between two horizontal lines corresponds to a deflection of the needle 1' to the e., and a fall 1' to the west. The line marked *o* is the magnetic meridian, or the mean daily position of the needle. The interval between two upright lines corresponds to an hour. The course begins at twelve at night, and ends at twelve the following night. At twelve at night, the magnet is 1½' e. of the mean position, and continues nearly in the same position, with only a slight westerly deviation, till 15 hours (three in the morning), when it veers eastward. At 20 hours (eight in the morning), it reaches its furthest e. point. From eight in the morning till one in the afternoon, it makes a sweep of 10' toward the w., and then stands about 6' to the w. of the mean. After one, it goes westward till midnight, when it again begins the same course. The needle stands in its mean position a little after ten in the morning, and a little before seven in the evening. The course here described is the course for the year. But the diurnal range is different in different months. In May, for instance, the average range between the extreme points is 12', which is the maximum range for the year; and in December, when it is a minimum, it is only 5' 28". The diurnal changes here described for Kew are much the same all over the n. magnetic hemisphere. The amount, however, is different. Near the magnetic equator the diurnal variation is little

or nothing, and it increases as we go northward. Captain Duperrey states that at or near the magnetic equator, the n. point of the needle in the morning shifts slightly e. or w. of the mean, according as the sun passes s. or n. of the station. In the southern magnetic hemisphere, the daily motions of the needle take place much in the same way as in the northern hemisphere, only the s. pole takes the place of the n. pole, and the direction of the deflections is reversed. The correspondence, and at the same time opposition, of the southern hemisphere is also shown from the time of maximum and minimum range. When the sun is in the northern signs of the zodiac, the range is a maximum in the northern, and a minimum in the southern hemisphere; and when the sun is in the southern signs, the reverse takes place. The diurnal variation is so small, that the ordinary compass-needle is not delicate enough to show it.

The *irregular variations* are those which break in upon the regular march of the diurnal variation, without in the main altering it. Instead, for instance, of the needle steadily going westward from 8 A.M. to 1 P.M., as shown in fig. 2, it makes, when affected by irregular variation, deflections eastward as well as westward, although it in

FIG. 2.

the main moves westward; so that the line between these hours, instead of being comparatively straight, would be an irregular zigzag. These disturbances of the mean course are sometimes considerable, amounting even to one or two degrees in extreme cases. On some days, the mean diurnal course is much disturbed, on others, very little; but it is never quite free from them. It has been found that places of the same longitude have similar disturbances at the same time; that those on opposite sides of the globe, or differing by 180° of longitude, have disturbances equal in amount, but opposite in direction; and that those situated 90° w. or e. of the disturbed regions, have little or no disturbance. The appearance of auroras is invariably accompanied by magnetic irregularities, and their effect extends far beyond the regions where they are visible. Earthquakes and volcanic eruptions have also a marked effect in this way. Humboldt gave the name of *magnetic storms* to these irregular disturbances. The frequency of these storms, and the amount of the diurnal variation, are found to be the greatest when sun-spots are most numerous. See SUN.

1. *Theories of Terrestrial Magnetism.*—The earliest theory was that suggested by Gilbert, in which it is supposed that a magnet in the middle of the earth extends from one magnetic pole to the other. On this supposition, the general phenomena of terrestrial magnetism may be accounted for—a needle, both by declination and dip, must point to the poles. This must always remain, from its simplicity, the popular theory on the subject. In consistency with his theory, Gilbert considered the n. pole of the magnet to be a s. pole, as he took the n. pole of the earth for his standard n. pole. If this theory were correct, the magnetic equator would be a great circle of the earth, and the magnetic poles would be 90° from it, which is far from the case. It is only a rough approximation to a just theory.

Halley endeavored to supplement Gilbert's theory by supposing two magnets of unequal strength crossing each other at the earth's center to be the cause of terrestrial magnetism. The theory of the two magnets or four poles was ably defended by Hansteen.

Barlow considered that the earth acted on the needle as if currents of electricity traversed it from e. to west. He imitated its action by wrapping a wire in parallel coils round a wooden globe, and causing a galvanic current to pass through it. Each turn of the wire represented a magnetic parallel, and the two ends of the coil the magnetic poles; and, to complete the analogy, the globe was movable on an axis, which stood in the same relation to the ends of the coil as the astronomical to the magnetic poles of the earth. When a small needle was placed on the globe, its declination and dip bore a striking resemblance to those of a needle similarly situated on the earth's surface. The objection to this theory is the difficulty of accounting for the origin of such currents in

the earth. To meet this, some suppose the earth to be a huge thermo-electric pile; and the heat of the sun falls on one side of it, currents are there generated which travel round the globe. But how, again, it may be asked, are the conditions of thermo-electricity implemented by the materials of the earth? This question still remains to be answered. The close connection between temperature and magnetism is shown by the diurnal variation of declination, the epochs of which closely correspond with those of the daily temperature, and by the fact that the isodynamic and isothermal lines manifest a marked correspondence. Sir David Brewster has also shown that there are two centers of maximum cold in the northern hemisphere, which are situated near to the two intensity poles.

Gauss did not start from any simple supposition of one or two magnets giving rise to the magnetism of the earth, nor did he assert or deny its electric origin. Considering the whole earth as magnetic, he aimed at determining how it must act as a whole at the different points on its surface. In order to make the equations he obtained theoretically in this attempt express the distribution on the earth, the magnetic elements of eight stations at a sufficient distance from each other on the earth's surface had to be ascertained and substituted in these equations. This done, from the longitude and latitude of any station he considered himself prepared to deduce its magnetic elements. The magnetic charts which he sketched, though founded on the imperfect observations to which he had access, are singularly in keeping with fact, and go far to establish the correctness of his reasonings.

The secular variations are as yet wholly unaccounted for. The cause of the diurnal variation is universally attributed to the sun. Secchi, who carefully studied the diurnal variation of the needle, considers that the sun, so far as they are concerned, acts upon the earth as a powerful magnet at a distance.

Historical Sketch.—The discovery of the change in declination at different places is generally attributed to Columbus, and was one of the many important observations of his memorable voyage across the Atlantic. Robert Norman, an instrument maker in London, first discovered the dip of the needle in 1576. He was led to it by finding that needles nicely balanced before magnetization had to be slightly loaded on the s. end, to keep them horizontal after being magnetized. Gilbert (1600) gave the first theory of terrestrial magnetism, viz., that of the single magnet. Halley, the astronomer-royal, published his theory of the four poles in 1683. In 1688 and 1689, at the expense of government, he made two magnetic voyages, the results of which he embodied in his charts of the lines of equal declination, published in 1701, which were the first magnetic charts ever published. In 1722, the diurnal variation was discovered by Graham, the celebrated instrument-maker of London. The first inclination chart was published by Wilke at Stockholm, 1768. Humboldt inaugurated the present system of careful observations of terrestrial magnetism by taking comparative measurements of the magnetic elements at Peru and Paris (1799–1803). Hansteen's work on the *Magnetism of the Earth* was published at Christiania, 1817; in 1826 he published the first isodynamic charts. Barlow (1831) suggested the electric origin of terrestrial magnetism. In 1831, captain Ross came upon the n. magnetic pole. In 1835, stations were established throughout Europe, and the observations were published by Gauss and Weber, 1836. Gauss (1833–1840) perfected his theory. In 1837, Col. Sabine published an isodynamic chart of the whole globe. Observations were made (1840–1854) at stations throughout the British empire by British officers, under the direction of Col. Sabine.

TERRESTRIAL TEMPERATURE. The distribution of heat over the globe is represented by isothermal lines, or lines drawn through all places having the same mean temperature.

The part of the globe having the highest mean annual temperature forms an irregularly shaped belt, lying along the equator, and comprised between the n. and the s. isothermals of 80°. On either side of this warm belt the temperature diminishes towards the poles; and the lines in a chart showing successively this diminution are, speaking in a very loose sense, arranged parallel to the equator, thus showing the all-predominating influence of the sun as the source of terrestrial heat. The coldest portion of the earth's surface is a small oval-shaped patch near to but not surrounding the n. pole, its mean temperature being —4°. Its narrowest diameter lies n. and s., nearly touching the pole on the one side, and extending on the other as far s. as 72° 30' n. lat. in 130° w. long. On looking at a chart representing the isothermal of 0°, one might be led to suppose that there are two centers of greatest cold, one n. of Siberia, and the other n. of British America. Such, however, is not the case—the apparent double center of greatest cold being solely due to the isothermals being drawn on Mercator's projection of the earth; for if an isothermal map be drawn on a polar projection, the lines of mean annual temperature inclose one connected space of greatest cold, and not two such spaces, as is not unfrequently stated.

While the decrease of temperature in advancing toward the poles corresponds in a general way to what may be called the solar climate, there are deviations brought about by disturbing causes too important to be overlooked. These disturbing causes are (1) the currents of the sea; (2) the prevailing winds; and (3) large surfaces of water which are frozen during part of the year.

The influence of an oceanic current depends on the temperature of the place it leaves and the place at which it arrives. Hence the great equatorial current, flowing from east to w. does not require to be considered here, because the heat remains the same throughout its course; but only those currents which convey the waters of the sea to higher or to lower latitudes. Of these, the most marked and important is the Gulf stream in the North Atlantic, which, by conveying warm water to the arctic regions, pushes the isothermals many degrees to the northward. There is a similar, though much feebler, current passing from the North Pacific to the Arctic Sea through Behring's strait, and there, accordingly, the isothermals are pushed a little to the northward. In the southern hemisphere, there are two currents, one discovered by Humboldt, passing from the Antarctic Ocean northward by the coast of Peru as far as Lima; the other flowing from the cape of Good Hope northward along the w. coast of Africa: these currents, flowing from colder to warmer latitudes, lower the temperature, and thus drive the isothermals toward the equator. Again, the great equatorial current, after impinging on the e. coast of Africa, turns southward, and by the warmth it imparts, pushes the isothermals into higher latitudes. For the same reason the current flowing southward past the coast of Brazil, raises the temperature in the e. of that country. The influence of these great currents is more distinctly marked in the forms of the isothermals for January and July. Thus, in January, when the relative excess of the temperature of the Gulf stream is greatest, the isothermals are driven very far to the north; and similarly in the southern hemisphere, the currents from the Antarctic Ocean being coldest in July, the isothermals are deflected more toward the equator during that month. The most remarkable lowering of the isothermals occurs in Labrador and Newfoundland during May and June, and is caused by the icebergs which then descend on these coasts from Davis's strait.

Since winds bring with them the temperature of the regions they have crossed, the equatorial current is a warm wind, and the polar a cold wind; also winds arriving from the ocean are not subject to such variation of temperature during the year as winds from a continent. As an atmosphere loaded with vapor obstructs both solar and nocturnal radiation, it follows that moist winds are accompanied with a warm temperature in winter, and a cool temperature in summer; and dry winds with cold winters and hot summers. The direction of mountain-ranges is also an important element to be taken into account in estimating the influence of winds on temperature. These considerations explain the position of the isothermals in the north temperate zone, where the prevailing wind is the s.w. or anti-trade (see WIND). In January, the western parts of each continent enjoy a comparatively high temperature, from their proximity to the ocean, whose high temperature the winds waft thither; and they are further protected from extreme cold by their moist atmosphere and clouded skies. But in the interior of the continents it is otherwise; for the winds getting colder as they advance, and being deprived of their moisture as they cross the mountains in the w., the soil is exposed to the full effects of radiation during the long winter nights, and as a consequence, the temperature rapidly falls. In the center of Siberia, the January temperature falls to -40° , which is 9° colder than the coldest part of the American continent; and this center of greatest cold lies near the eastern part of the continent of Asia. On the other hand, in July, the interior of continents is much warmer than their western parts. Hence the interior and eastern parts of Asia and America are characterized by extreme climates, and the western parts by equable climates.

The great fresh-water lakes of North America—lakes Superior, Huron, Erie, Michigan, Ontario, Bear lake, etc.—exercise an important influence on the climate of the central parts of North America, for in winter, America, with its frozen lakes, is a truly unbroken continental mass, and its winter climate is therefore continental; whereas in summer its numerous large sheets of fresh water communicate to it many of the features of an insular summer climate.

The whole effect of the disturbing causes is seen at once, if we compare the observed temperature of a place with its normal temperature, that is, the temperature due to it in respect of its latitude. In the northern hemisphere, in January, the sea and the western parts of the continents are in excess of their normal temperature; elsewhere, there is a deficiency. There are two centers of excess, one to the n.e. of Iceland, amounting to 41° ; the other in Russian America, amounting to only 18° ; and two centers where the temperature is deficient, one at Irkutsk, amounting to 41° ; and the other w. of Hudson's bay, amounting to 27° . In July, the United States, Europe, Asia, the Indian ocean, the n. of Africa, and the extreme n. of South America, have their temperature in excess, while elsewhere it is deficient. The centers of excess are: n. of Siberia, $13^{\circ}.5$; Red sea, $11^{\circ}.0$; and n.w. of the United States, $4^{\circ}.5$; and the centers where the temperature is deficient are: the entrance to Hudson's bay, $11^{\circ}.0$; and the Aleutian islands, $11^{\circ}.0$.

TERRIER, a small kind of dog, remarkable for sagacity, vivacity, courage, and eagerness in the pursuit of "vermin," which it readily follows into burrows; whence apparently the name terrier, from Lat. *terra*, the earth. The courage of the terrier, however, is such that it will readily attack animals much larger than itself; and it has been observed in India that terriers will fearlessly rush at the largest carnivora, when even the bull-dog hesitates. Terriers are of great use for killing rats in places much infested by them. They are also used for compelling the fox to leave his retreat; and a large

variety called the *saufinder*—that is, boar-seeker—is employed in Germany to rouse the fiercest beasts of the forest from their lairs. The varieties of terrier are numerous. In Britain, two are particularly prevalent, known as Scotch and English terriers—the former with long, rough, wiry hair, with which even the face is much covered; the latter with smooth, short hair. The ears are either erect and pointed, or have pendent tips. The Skye terrier is a breed of Scotch terrier, peculiarly prized. The BULL TERRIER is probably a cross between the terrier and the bull-dog (q.v.).

TERRITORIES, in the United States and under similar governments, are those portions of the public lands set off by congress and still under its direct authority, while having the capacity to become states whenever congress gives its consent. Each territory has a governor, a judiciary, and other administrative officers appointed by the president; and has a territorial legislature, the exercise of whose powers, limited in their degree, is subject to congressional revision. Usually, as soon as a territory has a population sufficient to entitle it to a representative in congress, it is empowered by act of congress to adopt a state constitution, whereupon it is admitted into the union. See ADMISSION OF NEW STATES.

TERRY, a co. in the Staked Plain of Texas; formed, 1876; unorganized, and attached to Martin co. for judicial purposes; 900 sq.m. Pop. '90, 21.

TERRY, ALFRED HOWE, b. Conn., 1827; educated at the Yale law school. He was clerk of the Connecticut superior and supreme courts, 1854-60; col. of a Conn. regiment at the beginning of the war of the secession; and took part in the first battle of Bull Run. In command of another Conn. regiment he was at the capture of Port Royal. He took command of Fort Pulaski after its capture; was made brig. gen. of volunteers in 1862, took part in the operations around Charleston, and at Forts Sumter and Wagner. In 1864 he led a division of the army of the James, participated in the Virginia campaign, and was at Bermuda Hundred and the siege of Petersburg. He led a second expedition against Fort Fisher in 1865, and took it by storm Jan. 15. He was soon made a brig. gen. in the regular army, and maj. gen. of volunteers for this victory. He assisted in the capture of Wilmington, and commanded the 10th corps during the North Carolina campaign; on the death of Gen. Hancock, was made maj.-gen., U.S.A.; died Dec. 1890.

TERRY, ELLEN ALICE (Mrs. E. A. WARDELL), was b. at Coventry, England, Feb. 27, 1848; and made her first appearance on the stage during Charles Kean's Shakespeare revivals in 1858, playing the parts of Manilius in *The Winter's Tale* and Prince Arthur in *King John*. When only fourteen she was a member of Mr. Chute's Bristol company, which included Mrs. Kendal and several other now prominent members of the profession. She made her debut in London, March, 1863, as Gertrude in *The Little Treasure*, and until Jan., 1864, played Hero in *Much Ado about Nothing*, Mary Meredith in *Our American Cousin*, and other secondary parts. In that year she married and left the stage, but reappeared again in Oct., 1867, in *The Double Marriage*, at the new Queen's theater, London. She afterwards joined Mr. and Mrs. Bancroft at the Prince of Wales's theater, where she acted the part of Portia. On Dec. 30, 1878, she made her first appearance at the Lyceum, and has since, in conjunction with Sir H. Irving, played in the longest runs ever known of *Hamlet*, *The Merchant of Venice*, *Romeo and Juliet*, and *Much Ado about Nothing*. She has also appeared as Viola in *Twelfth Night*, Henrietta Maria in *Charles I.*, Camma in Tennyson's tragedy of *The Cup*, and Ruth Meadows in *Eugene Aram*. She achieved immense success as Marguerite in W. G. Wills' play of *Faust*. She accompanied Sir Henry on his American tour in 1887 and many times thereafter, and afterwards reappeared at the Lyceum in *Faust*, and (1888) at the same theater played as Lady Macbeth and in *Dead Heart*. In Sept., 1890, Miss Terry appeared as Lucy Ashton in *Ravenswood*, with great success.

TERSCHELLING, one of the chain of islands to the n. of Holland, lies in 53° 24' n. lat., the principal villages being Hoorn, Westerschelling, and Midsland. It consists of fertile, arable, and meadow lands, is protected on the s. by large dykes, and in other parts by downs, which are carefully preserved. Area about 45 sq. m. Pop. '89, 3730. There is a good haven, a shipbuilding-yard, woolen dyeworks, etc.

TERTIAN FEVER. See AGUE.

TERTIARY (Lat. *Tertiarius*, one of the third rank), a name given by church writers to a class in the Roman Catholic church, who, without entering into the seclusion of a monastery, aspire to practice in ordinary life all the substantial obligations of the scheme of virtue supposed to be laid down in the gospel. Whatever earlier traces of this institution may be observable, there is no dispute that it was under St. Francis and the mendicant orders generally that the institute of tertiary, reached its full development. The rules of the institution of tertiary, such as they have since substantially been maintained, were made public in 1221. The associates must, of course, all be members of the church; and it is moreover required that all shall be of good repute and blameless life. The intending members must restore all ill-gotten goods, must renounce all evil practices, and abandon all feuds and enmities with their neighbors. Wives cannot be received without the consent of their husbands. The obligation of tertiary once accepted, is irrevocable, unless the party should be released, or should enter into a more strict religious order. The members are required to renounce luxury

of life, profane exercises and amusements, costly or unseemly dress, and the use of arms, except in the necessity of self-defence. They must frequent the sacraments: hear mass, if possible, daily; observe the fasts of the church, as well as certain special austerities; avoid contention, litigation, and unnecessary oaths; cultivate charity toward all, with special obligations toward needy, sick, or afflicted brethren, and practice with more than common fervor the great Christian virtues. The tertiary are placed under the authority of superiors elected at intervals, and for a stated period, and are liable to an annual visitation, conducted by a priest appointed for the purpose. It is to be observed, however, that none of these obligations were supposed to bind the members under pain of mortal sin.

TERTIARY, the term applied in the science of geology (q.v.) to all the strata of the earth's crust above the cretaceous rocks, with the exception of those superficial beds which have recently been raised to a distinct group, under the title of the quaternary system, or recent period. There is considerable difference of opinion as to the division-line between the two systems, some including the boulder clay and its associated beds in the one, and some in the other group. Tertiary is synonymous with *cainozoic*, and is divided into the *pleistocene* (q.v.), *miocene*, and *eocene* (q.v.) periods.

TERTULLIAN, a father of the church, and one of the earliest who used the Latin language in written compositions. In one passage, the genuineness of which there is no reason to doubt, he calls himself *Septimius Tertullianus*. The best manuscripts call him *Quintus Septimius Florens Tertullianus*. He was the son of a proconsular centurion—that is, a centurion who attended on the proconsul. He was born in Carthage. He was brought up a heathen, and from his own writings we learn that he was licentious in his conduct, and fond of the public shows. We know nothing more of his heathen life. Eusebius describes him as a man exceedingly well acquainted with the laws of the Romans, and his writings bear out the assertion. From this circumstance, some have identified him with a Tertullianus whose name occurs in the index of the *Pandects*, and have supposed that he acted as an advocate; but the supposition is a mere conjecture. We know nothing of his conversion. He became a presbyter in the church, but whether he held this office in Rome or in Carthage, is matter of dispute, and there are no data to determine the question. It is certain that he visited Rome, and was well acquainted with the affairs of the Roman church. He also married; and as his wife was a Christian, it is supposed that his marriage took place after his conversion. After remaining a presbyter until he had reached middle age, he became a Montanist. Jerome attributes his adoption of Montanism to the insulting treatment which he received at the hands of the Roman clergy. But this is not likely an entirely accurate account of the matter. Jerome himself had been ill treated by the Roman clergy, and was therefore inclined to blame them; and in the character and general tendency of Tertullian's opinions, we have ample explanation of his passing over to Montanism. See **MONTANUS**. He lived to a good old age, remaining a Montanist to the last. We have no clue to precise dates in the history of Tertullian. Jerome states that he flourished under Severus and Antoninus Caracalla. Allix places his birth at 145 or 150 A.D., and his death at about 220 A.D.; but these are conjectures.

Tertullian was a man of strong and violent passions: he loved and hated with intensity. He possessed considerable culture, and was well versed in Roman law, in ancient philosophy, history, and poetry. He was not deficient in philosophical power, but he was narrow, bigoted, and uncharitable. He shows no sympathy with Greek speculation or with freedom of human thought; and he shows little sympathy with the joys and pleasures of man, being strongly inclined to asceticism. We need not wonder, therefore, that he came to believe in the paraclete of Montanus as the revealer of the perfection of Christianity, and that he adopted the Montanist opinions, that second marriages were adulteries, and that it was unlawful to flee in times of persecution, and wrong to receive the lapsed back into the communion of the church.

His writings are numerous. Attempts have been made to divide them into those which were written before he became a Montanist, and those written after that event; but the attempts have failed; for in treating many subjects he would have no occasion to say a word in regard to the paraclete, second marriages, or persecution.

His works are interesting, throwing much light on the internal circumstances of the church, on the social questions which perplexed Christians, on the opinions of heretics, and on the development of doctrine. Of his theology, Neander remarks: "In Tertullian we find the first germ of that spirit which afterward appeared with more refinement and purity in Augustine, as from Augustine the scholastic theology proceeded, and in him also the reformation found its point of connection." Among the peculiar opinions which he held may be mentioned his belief in the corporeality of the human soul.

His writings had great influence on the subsequent ages, but especially on Cyprian. Jerome says: "I saw at Concordia, in Italy, an old man named Paulus. He said that, when young, he had met at Rome with an aged amanuensis of the blessed Cyprian, who told him that Cyprian never passed a day without reading some portion of Tertullian's works; and used frequently to say: *Give me my master*, meaning Tertullian."

There are many editions of Tertullian; the best is by Franciscus Oehler (3 vols. 8vo, Lps. 1853). The third volume contains the principal dissertations on the life and writ-

ings of Tertullian. The works of Tertullian, with many dissertations and notes, form the first and second volumes of Migne's *Patrologia Latina*. The English reader will find a full and satisfactory account of Tertullian's life, writings, and opinions in bishop Kaye's *Ecclesiastical History of the Second and Third Centuries, Illustrated from the Writings of Tertullian* (8vo, 2d ed. Cambridge, 1829); and in Neander's *Anti-gnosticus or the Spirit of Tertullian*, translated by J. E. Ryland. A good translation of Tertullian's works will be found in Clark's *Anti-Nicene Christian Library*, edited by Drs. Roberts and Donaldson.

TERUEL, a province in n.e. Spain, adjoining Tarragona, Valencia, Saragossa, Castellon, Cuenca, and Guadalajara, and forming part of Aragon; drained by the Tagus, Guadalupe, Guadalaviar and smaller streams; 5,494 sq. m.; pop. '87, 241,865.

TERZA RIMA (Italian, *terza*, third, and *rima*, rhyme). A method of versification in vogue among the Italian poets, and borrowed by them from the troubadours. Three lines make a stanza, of which the first and third line rhyme, the second furnishing the exterior rhyme of the following triplet, and so on. Example :

Noi leggevamo, un giorno, per diletto
Di Laucilotto, e come amor lo strinse
Soli eravamo, e senz' alcun sospetto.

Terza rima is not common in English and French poetry.

TESCHEN, a t. of Austrian Silesia, on the right bank of the Olsa, 60 m. w.s.w. of Cracow. Pop. '90, 15,220. Here, in 1779, a treaty of peace was concluded between Maria-Theresa and Frederick II., by which the dispute of the Bavarian succession was brought to an end.

TESLA, NIKOLA, was born in Austro-Croatia in 1857. After a course in the schools of his native province, he went to Gratz to prepare for work as a professor of mathematics and physics, but becoming interested in electricity, he left Austria for Paris in 1881, and the next year, came to America. He is the inventor of various minor electrical appliances, but is principally known for his researches in the matter of alternating currents of high frequencies and very high potentials. He received the degree of LL.D. from Columbia College in 1894.

TESSERÆ, the small square tiles or cut stones used in forming tessellated pavements.

TEST ACTS, otherwise called *corporation acts*, the popular name given to two English statutes imposing certain oaths on the holders of public offices. Act 13 Car. II. c. 2, directs that all magistrates shall take the oaths of allegiance and supremacy, as well as an oath renouncing the doctrine that it is lawful to take arms against the king, and provides that they must receive the communion according to the rites of the church of England within a year before their election. Act 25 Car. II. c. 1, imposed the like conditions on the holders of all public offices, civil and military, and obliged them in addition to abjure all belief in the doctrine of transubstantiation. These acts, which were practically evaded to a large extent by means of an act of indemnity passed every year, were repealed by 9 Geo. IV. c. 17, in so far as regarded the administration of the sacrament, for which a declaration set forth in that act was substituted. A statute of William IV. substituted a declaration for an oath in most government offices. A new form of oath has been substituted for the oaths of supremacy, allegiance, and abjuration.

TESTAMENT. See BIBLE.

TESTAMENT. See WILL.

TESTER, or **TESTOON**, a flat canopy over a tomb, pulpit, etc.

TESTICLES. See REPRODUCTION.

TESTING, in chemistry, embraces a series of processes, the details of which would occupy far more space than the general plan of this work would admit of. Indeed, testing may be regarded as equivalent to qualitative analysis. As a simple illustration of the process of testing, we will assume that the most common of all chemical compounds, a salt, is submitted for examination. The student must pursue some such course as the following: 1. He must examine the dry substance before the blow-pipe, and note whether (a) it is volatile, as are the salts of ammonia and mercury; or (b) fusible, as are the salts of potash and soda; or (c) infusible, as are the salts of zinc, alumina, magnesia, lime, strontia, and baryta; or (d) reducible, as are the salts of silver, tin, lead, bismuth, antimony, and cadmium; and (e) whether it gives a coloration to the borax bead, and what that color is. 2. Having made his blow-pipe examination, he must bring his substance to a finely-divided state, and dissolve it, if possible, in water, and if it is insoluble in that fluid, even with the aid of heat, in hydrochloric or nitric acid. The solution, whether in water or acid, to which no test or reagent has been applied, is termed by Odling (*A Course of Practical Chemistry*, 2d ed. 1865) and others the *original solution*; and to this are added various tests, such as hydrogen sulphide, ammonium sulphide, ammonia, nitrate of silver, etc. The most common effect resulting from the addition of a gaseous or liquid reagent is to cause a *precipitate* or solid deposit of either the base or acid sought for. These precipitates differ in their color, consistency, etc.; and the student must note not only the color of the precipitate (although this is the most important point).

but also whether the deposit is crystalline, gelatinous, clotty, etc. 3. He must then ascertain to which group the base he is seeking for belongs. There are three great groups of bases; the members of the first group being precipitated from their acid or acidified solutions by hydrogen sulphide (hydrosulphuric acid); those of the second group not being thrown down by this reagent, but being precipitated from neutral solutions by hydrosulphate of ammonia (ammonium sulphide); while those of the third group are not thrown down by either of these reagents. The first group includes tin, arsenic, antimony, bismuth, mercury, lead, silver, copper, and cadmium; the second, nickel, cobalt, manganese, iron, chromium, aluminium, and zinc; and the third, barium, strontium, calcium, magnesium, potassium, sodium, and ammonia. (See Odling, *op. cit.* p. 64). 4. Having ascertained to which base the group belongs, the next point is to identify it. For information on this point the reader is referred to any of the standard works on qualitative analysis, or on practical chemistry. 5. The base being thus determined, it remains to determine the acid, and in searching for it the student will be much assisted by a knowledge of the solubility of the most important classes of salts. Knowing, for example, the insolubility of the sulphates of baryta and strontia, he need not search for sulphuric acid in a soluble salt of one of these earths. On the other hand, a salt insoluble in water is not likely to be a nitrate or chlorate, or acetate or chloride (the only chlorides insoluble in water being chloride of silver and calomel). We cannot enter into the testing for acids further than to observe that the nitrates and chlorates deflagrate; the tartrates and citrates char; the carbonates effervesce when acted on by an acid more energetic than carbonic acid; the silicates, borates, and benzoates are precipitated by hydrochloric acid; and the arseniates and chromates react with hydrogen sulphide. The presence of any particular acid is more or less indicated by its behavior, while still in union with the base, with strong sulphuric acid, which in many cases causes the evolution of characteristic fumes or vapors; and among the tests especially applicable for the detection of the acids (in acid solutions) are solutions of nitrate of baryta, nitrate of silver, chloride of calcium, and perchloride of iron. As the above remarks apply merely to the detection of the base and acid contained in a single salt, it will readily be understood how much the difficulties are increased when there is a mixture of several salts, or where, in place of a metallic oxide, an organic base is present, or where we have to deal with a complicated mixture of organic and inorganic substances, as, for example, in the investigation of the contents of the stomach in a case of suspected poisoning.—The following works on the subject may be referred to: Fresenius's *Qualitative Analysis*; Noad's *Qualitative Analysis*; Greville Williams's *Outlines of Chemical Manipulation*; Bowman's *Practical Chemistry*; and Odling's *Practical Chemistry*.

TEST-PAPERS are made by dipping unsized paper into an alcoholic solution of a vegetable coloring matter which changes color when exposed to the action of an acid or alkaline solution. The paper, after being gently dried, is cut into slips of a suitable size. Hence, by dipping the appropriate test-papers into any solution, we can ascertain whether it is acid, alkaline, or neutral. Litmus and turmeric are most commonly used as the coloring matters; litmus for the detection of acids, and turmeric for that of alkalis.

TEST TUBE. A thin cylindrical glass tube, with a rounded bottom and a smooth lip, extensively used in chemical experimentation, especially for testing and analyzing liquids. While comparatively inexpensive they are indispensable in the chemical laboratory. When made of the best German glass they are not liable to break in the handling and can be heated to a considerable temperature with impunity. They are manufactured of various lengths and sizes, but the most convenient size for general use is about six inches long and $\frac{1}{4}$ of an inch in diameter. Distilled water and a test tube brush are their best cleansing agents.

TESTUDO. See TORTOISE.

TESTUDO, in ancient warfare, was a defensive arrangement of the shields, by means of which a body of men advancing against a wall for assault or mining sought to protect themselves from the darts and weapons of the defenders. The men standing in close order joined their shields above their heads, the edges overlapping, until the whole resembled the shell of a tortoise (*testudo*).—The name was also applied to a machine moving on wheels, and roofed over, under which soldiers worked in undermining or otherwise destroying the walls in a siege. See BATTERING-RAM.

TET'ANUS (derived from the Gr. *teinein*, to stretch), is one of the most formidable diseases of the nervous system, and is characterized by an involuntary, persistent, intense, and painful contraction or cramp (see SPASM) of more or less extensive groups of the voluntary muscles, nearly the whole of the body being sometimes affected. There is usually a certain degree of order in which the different sets of muscles are affected. The muscles of the neck, jaws, and throat are almost always the first to give evidence of the presence of the disease. "The patient," says Dr. Watson, who has written a most graphic description of this terrible malady, "feels a difficulty and uneasiness in bending or turning his head, and supposes that he has got what is called a stiff neck. He finds also that he is unable to open his mouth with the customary facility. At length the jaws close; sometimes gradually, but with great firmness; sometimes (it is said) suddenly and with a snap. In four cases, perhaps, out of five, the disease begins in this way with

trismus or *lock-jaw*; so that this last is the vulgar name for the complaint. Along with this symptom, or very soon after it, the muscles concerned in swallowing become affected; and in a short time there comes on, what is often the most distressing part of the disorder, an acute pain at the lower part of the sternum, piercing through to the back. This pain depends, it can scarcely be doubted, upon cramp of the diaphragm, and is subject to aggravation in paroxysms. The spasm extends to the muscles of the *trunk*; to the *large* muscles of the extremities; the muscles of the *face*; and last of all, in general to the muscles of the tongue, and of the hands and fingers, which often remain movable at the will of the patient, after all the other voluntary muscles of the body have become fixed."—*Lectures on the Principles and Practice of Physics*, 4th ed., vol. i. p. 568. The muscles that are affected remain permanently contracted till either recovery or death ensues, and some of them, as, for example, the muscles of the abdomen, are so rigid, as when struck by the fingers, to resemble a board, although a perfect remission of the spasm scarcely ever occurs, except sometimes during sleep. Exacerbations of the spasms, on the other hand, commonly occur every ten minutes or quarter of an hour, usually beginning by an increase of the pain at the sternum, and lasting for two or three minutes; and as the disease advances, these paroxysms become more frequent. The powerful muscles of the back generally overcome the muscles in the front of the body, and when this excess of morbid power in the back is marked, the result is that the patient during the paroxysms rests solely on his head and heels, while his body is raised in an arched form. Occasionally the muscular contraction predominates in the opposite direction, and brings the head and knees in contact; and still more rarely, the body is bent to one side.

During the exacerbations, the face of the patient often presents a positively frightful appearance. The tongue is apt to get bitten during the contractions, which are occasionally so violent as to break the teeth, rupture powerful muscles, and at least in one case, to fracture the thigh-bone. Death usually results from a mixture of causes, but mainly from apnœa (breathlessness), due to the fixed condition of the respiratory muscles, associated with asthenia (loss of power), and flagging of the heart's action.

There are two principal causes of this disease, viz. (1) exposure to cold and damp, and (2) bodily injuries. When tetanus arises from the *first* of these causes, it is termed *idiopathic*; and when from the second, *traumatic*. Idiopathic tetanus is so rare, at all events in this country, that we may pass on at once to the consideration of the traumatic variety. The disease is liable to follow any kind of injury, from a trifling cut or scratch to a compound fracture or the most severe operation, and is much more common in tropical than in temperate climates. The following table, given by Mr. Poland in his article "Tetanus" in Holmes's *System of Surgery*, vol. i. p. 306, gives the relative proportions which the occurrence of tetanus bears to various classes of surgical lesions observed at Guy's hospital during seven years:

There were of—

| | | |
|---------------------------------|------|-----------------------------|
| Major and minor operations..... | 1364 | cases—tetanus occurred in 1 |
| Wounds of all varieties..... | 594 | " " " 9 |
| Injuries and contusions..... | 856 | " " " 1 |
| Burns and scalds..... | 458 | " " " 3 |
| Compound fractures..... | 396 | " " " 9 |
| Total..... | 3668 | 23 |

From the large experience thus afforded, it appears that tetanus is most frequently met with in the more severe varieties of injury and accident, such as compound fractures, burns, and injuries to the fingers and toes. It is still a disputed point, whether the seat of the injury forms any special connection with the disease. Hennen, one of our greatest authorities on military surgery, observed it oftener after wounds of the elbow and knee; others, again, more frequently from injuries of the thumb and great toe. There is certainly a popular belief that wounds of the ball of the thumb are especially likely to be followed by tetanus.

The interval between the reception of the injury and the first tetanic symptoms commonly varies from the 4th to the 14th day, and rarely exceeds 22 days, some time in the second week being the most common period. As a general rule, the more rapidly the disease comes on, the more fatal will be the result.

Mere *trismus* or *lock-jaw* may be induced by affections of the teeth, especially by difficult dentition of the wisdom-teeth; but this is a purely local affection, in which the muscular contraction, though persistent, is never increased by painful spasmodic paroxysms, and which usually disappears on the removal of the exciting cause; and the general knowledge of this fact may tend to remove unnecessary terrors. Hysteria sometimes mimics the phenomena of tetanus with marvelous fidelity; and hydrophobia and tetanus have been mistaken for one another, in consequence of the spasm of tetanus sometimes affecting the muscles of deglutition, and inducing a fear of swallowing. There is, however, seldom any serious difficulty in detecting the difference between tetanus and any other disease. But there is a form of poisoning which produces almost every symptom of tetanus, and which may be termed *artificial tetanus*. If strychnia or brucia, or their salts, or vegetable matter containing either or both of these alkaloids, as *nux vomica*.

St. Ignatius's beans, or the juice of the *upas tiente*, be administered, either by the stomach or by inoculation, into the system, it induces all the symptoms of intense tetanus, and there is no test by which to distinguish the results of the disease and of the poisoning, except that, according to Dr. Christison, the disease never proves so quickly fatal as the rapid cases of poisoning with strychnia. See *NUX VOMICA*.

In the way of treatment, almost every known medicine has been prescribed, and whatever plan be adopted, a vast majority of the cases terminate fatally. As is the case with certain fevers, so tetanus seems to have a definite course to run; and as Mr. Poland wisely suggests: "All we can do is to enable our patient to weather out the storm by giving him as much strength as possible, and not adding fuel to the fire by all sorts of applications and internal remedies, which have over and over again signally failed. If we can help our patient on one day after another, we gain much: constant watching and constant attention are required by night as well as by day; an unflinching perseverance on the part of the sufferer in carrying out these views; besides the avoidance of all causes of excitement, and more especially the cold air or winds; taking care to preserve a uniform temperature as much as possible." When, in consequence of the strong contraction of the muscles of the jaw, it is impossible to open the patient's mouth, food and physic should be introduced into the stomach by means of a flexible tube passed through one of the nostrils. See *TRISMUS NASCENTIUM*.

TETANUS, or LOCK-JAW, occurs in most of the domesticated animals, but most frequently in horses and sheep. It is usually produced by cold and wet, by intestinal worms, obstinate constipation, or injuries. The symptoms usually come on gradually, involve tolerably equally most of the muscular structures, which become hard and rigid; the nose is protruded, the limbs move stiffly, the tail is upraised, the bowels are constipated. The patient must be kept perfectly quiet, and in an airy but tolerably warm place, and plentifully supplied with cold water, and with soft, sloppy, but tolerably nutritive food, which he will usually greedily suck in through his firmly-closed teeth. A full dose of purgative medicine must at once be given; extract of belladonna repeated twice or thrice daily is occasionally serviceable; any discoverable wound or injury should be fomented or poulticed; bleeding, sedatives, and all causes of irritation must be avoided. In adult animals most cases are fatal; but among young animals, especially when the attack results from exposure to cold, many recoveries occur.

TÊTE À TÊTE (Fr., "head to head,") denotes conversation of an easy, confidential nature—a familiar chat. It is also the name of a small piece of furniture resembling a sofa, intended for seating two persons. The *tête-à-tête* is sometimes formed of two chair-like seats which are attached and face in opposite directions.

TETRAHEDRON (Gr. *tettares*, four, *hedra*, a side), one of the five regular geometric solids, is a solid bounded by four equilateral triangles. The best idea of it is gained by considering it as a triangular pyramid, whose three sides and base are equilateral (and therefore equal) triangles. It is a form assumed by some crystals, and in crystallography is considered as a secondary form of the octahedron (q. v.), produced by removing the alternate angles or edges of the latter.

TETRALOGY. 1. In Greek drama, three tragedies and a satyric drama presented in sequence. The satyric drama was in some cases connected with the tragedies in subject, but its main purpose was to relieve the tension caused by the trilogy. The tetralogy represents the last stage in the development of Attic tragedy.

2. A musical drama in four parts. Wagner's most famous tetralogy contains *Rheingold*, *Die Walküre*, *Siegfried*, *Götterdämmerung*. See *TRILOGY*.

TETRAPOLITAN CONFESSION, the creed of a body of Lutherans who held the doctrine of Carlstadt and of Zwingli concerning the Lord's-supper. It was drawn up by Bucer, 1531, was defended by Capito, and presented at the diet of Augsburg. The four cities which gave it a name—Constance, Strasbourg, Memmingen, and Lindau—held to it for many years.

TET RARCH (Gr. *tetrarches*, Lat. *tetrarcha*, "governor of the fourth part," i. e., of a country), a title originally designating what is signified by its etymology, the governor of one of four divisions of a kingdom or country; but, in the usage of the later Roman empire, given undistinguishingly to all minor rulers, especially in the east, possessing sovereign rights within their territory, but dependent on the emperor, and in many cases removable at his pleasure. This was especially the case in Syria, where the princes of the family of Herod are called indiscriminately by this title (Luke iii. 1) and by that of king (Matt. xiv. 9). The tetrarch in this latter sense was in truth a sovereign, although a dependent sovereign; and there are instances in which it seems to have been applied to really independent sovereigns of small principalities.

TETTER, the popular name for skin diseases of the kind described under *PSORIASIS* and *HERPES*.

TETUAN, a seaport t. and small province on the n. coast of Africa, 22 m. s. of Ceuta and 40 m. s. of Gibraltar. Pop. 25,000. It is surrounded by walls, flanked with towers, and is defended by a castle. Tetuan was taken by the Spaniards under O'Donnell (q. v.), Feb. 1860, but was evacuated next year.

TETZEL, or **TEZEL** (properly *Diez* or *Diezel*), JOHN, well known in connection with the controversy regarding indulgences, out of which the first beginnings of the reforma-

tion took their rise, was b. at Leipsic between 1450 and 1460. His father was a goldsmith of that city. Tetzel, after completing the ordinary studies of the period in the university, entered the Dominican convent of St. Paul in 1489, and soon established a reputation as a popular and effective preacher. His personal character is a subject of much controversy. The questions as to the teaching of Tetzel are more important. His ability and success as a preacher led to his being intrusted with the charge of preaching an indulgence, first on behalf of the Teutonic knights, and afterward, in 1516, on the far more momentous occasion of the celebrated indulgence published in favor of contributors to the fund for building the church of St. Peter's at Rome. In the discharge of this commission it cannot be doubted that Tetzel went to extremes which it is impossible to justify; but the worst charges, and especially that of preaching the efficacy of indulgences without repentance, and of offering anticipatory pardons for future sin, are strongly denied by Roman Catholic writers as being contradicted not only by contemporary authorities, but also by the very instructions contained in his official commission. Much of the obloquy which he drew upon his cause was produced by the pomp and apparent luxury in which he traveled about upon his mission. It was in opposition to the preaching of Tetzel that Martin Luther published his celebrated theses, on Oct. 31, 1517. Tetzel replied first by publicly burning these obnoxious propositions; but he afterward published a series of counter-theses (which were burned in retaliation by the students of the university of Wittenberg); and in May, 1518, a detailed reply to Luther's celebrated sermon on indulgences. On the arrival of the papal delegate Miltitz, Tetzel addressed to him a letter in reply to the charges of his adversaries; but, notwithstanding this defense of his conduct, he was summoned to appear before Miltitz in Leipsic in the January of the following year, and underwent a severe rebuke for the excesses in language and the improprieties in proceeding which had brought so much scandal upon the church. Miltitz threatened him, moreover, with the severest animadversions on the part of the pope. He was required in consequence to withdraw to his convent at Leipsic, where he died in the August of the same year, 1519, according to some of the plague, but according to another account, of the chagrin and mortification resulting from the judgment of the papal representative.
